Effects of incidental take on survival and reproduction of reptiles and amphibians are likely during construction. Dewatering for construction activities has the potential to result in injury or death to amphibian eggs or tadpoles, and construction equipment poses a risk of enhanced mortality to all reptiles and amphibians, particularly those that move at a slower speed, such as salamanders. Snakes shed their skin multiple times annually. While shedding, snakes have reduced mobility and may be more vulnerable to incidental take during construction (Ministry of Natural Resources and Forestry, 2018). Additionally, common gartersnakes often hibernate communally, within a variety of structures including mammal burrows, voids in roost systems, and rock piles and crevices (Rowell, 2012). Incidental take of multiple eastern gartersnake is possible through the destruction of hibernacula caused by the construction of the Project.

Collisions with Vehicles and Equipment

Survival and Reproduction

Effects on the survival and reproduction of reptiles and amphibians from collisions with vehicles are very likely during construction and were also noted as a concern by Indigenous communities including Métis Nation of Ontario (Métis Nation of Ontario,

2023) and Kashechewan First Nation (MNP LPP, 2024a). The reptiles and amphibians present in the study area are small and slow moving, making them sensitive to incidental mortality from vehicle traffic. Common gartersnakes may also use areas such as roads and other cleared areas for thermoregulation. Across common gartersnake range road mortality is considered the biggest threat to populations (Colino-Rabanal and Lizana, 2012). Due to their preference for upland habitats and the boarders of watercourses and wetlands, the highest mortality rates for common gartersnake are expected to occur in areas where the road right-of-way crossed upland terrestrial habitat adjacent to wetlands and watercourses (Rowell, 2012; Jones et al., 2024).

During construction, public access to the Community Access Road will not be permitted.

Areas with wetland habitat on one or both sides of the road experience high amphibian mortality rates (Colino-Rabanal and Lizana, 2012). Animals moving across the work area will also experience an elevated risk of mortality. Construction may also take place at night while amphibian species are likely to be most active, adding to the risk for these species.

9.4.3.3.15.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

Mitigation measures will be implemented to avoid, minimize, and restore the effects of habitat loss and alteration from the Project on reptile and amphibian habitat availability, distribution, and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

The following mitigations will be implemented during construction to limit effects from habitat loss and alteration on amphibians and reptiles:

- A cleared width of less than 100 metre will be maintained unless otherwise required for construction;
- Vegetation clearing activities will be limited to the extent necessary for construction;
- All temporary construction infrastructure will be reclaimed as soon as possible following construction;
- Buffer zones of 30 metre will be maintained around waterbodies, clearing of riparian vegetation will be limited to the extent practicable and to the requirement of the access road and alignment clearing width only;
- Additionally, an Environmental Protection Plan and a Cleanup and Reclamation Plan will be developed and implemented;

- Where necessary, seedling planting will occur to improve reclamation success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified;
- Reclamation plans will be confirmed through engagement with Indigenous communities, the Ministry of Natural Resources and local foresters;
- Effectiveness of reclamation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities; and
- If required, adaptive management will be employed to modify or enhance any reclamation efforts.

Sensory Disturbance

Mitigation measures will be implemented to avoid, minimize, and restore the effects of Sensory Disturbance from the Project on reptile and amphibian habitat availability, and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

The following mitigation measures will reduce the effect of sensory disturbance on reptiles and amphibians:

- Construction traffic will be restricted to designated areas;
- During construction, access to the Community Access Road corridor will be restricted to construction personnel;
- Noise-producing equipment will be fitted with noise-reducing components, where feasible, and these components will be maintained;
- Unnecessary idling of vehicles and equipment will be limited on construction sites;
- Industry best practices will be used for blasting activities, including scheduling when in the vicinity of sensitive wildlife sites;
- Forest buffers will be retained around quarries to reduce noise, where feasible;
- Speed limits will be enforced at work areas during construction;
- Wildlife awareness training will be provided for road construction workers to reduce vehicle speeds and associated noise and dust emission levels; and
- Best management practices and environmental approval conditions, permits, or authorizations issued for the Project will be followed, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources.

Incidental Take

Mitigations outlined will be implemented to minimize effects from incidental take on reptile and amphibian survival and reproduction in the wildlife effects assessment Local Study Area during construction.

The following mitigation measures will reduce the effect of incidental take on reptiles and amphibians:

An Environmental Protection Plan will be developed that includes a worker awareness program. These are some additional mitigation measures:

- Construction traffic will be restricted to designated areas.
- Speed limits will be enforced on site during construction activities.
- Any reptiles or amphibians found within work areas will be relocated to suitable habitat nearby. Safe handling practices will be used to move turtles, snakes and other herpetofauna to areas away from the construction (for example, Ontario Species at Risk Handling Manual: For *Endangered Species Act* Authorization Holders).
- Construction personnel will traverse the path of construction equipment, to induce frogs, toads, and snakes to be scared away from the path of oncoming machinery.
- The Project footprint will be limited to the extent feasible; and,
- Calcium salts will not be used for dust control.

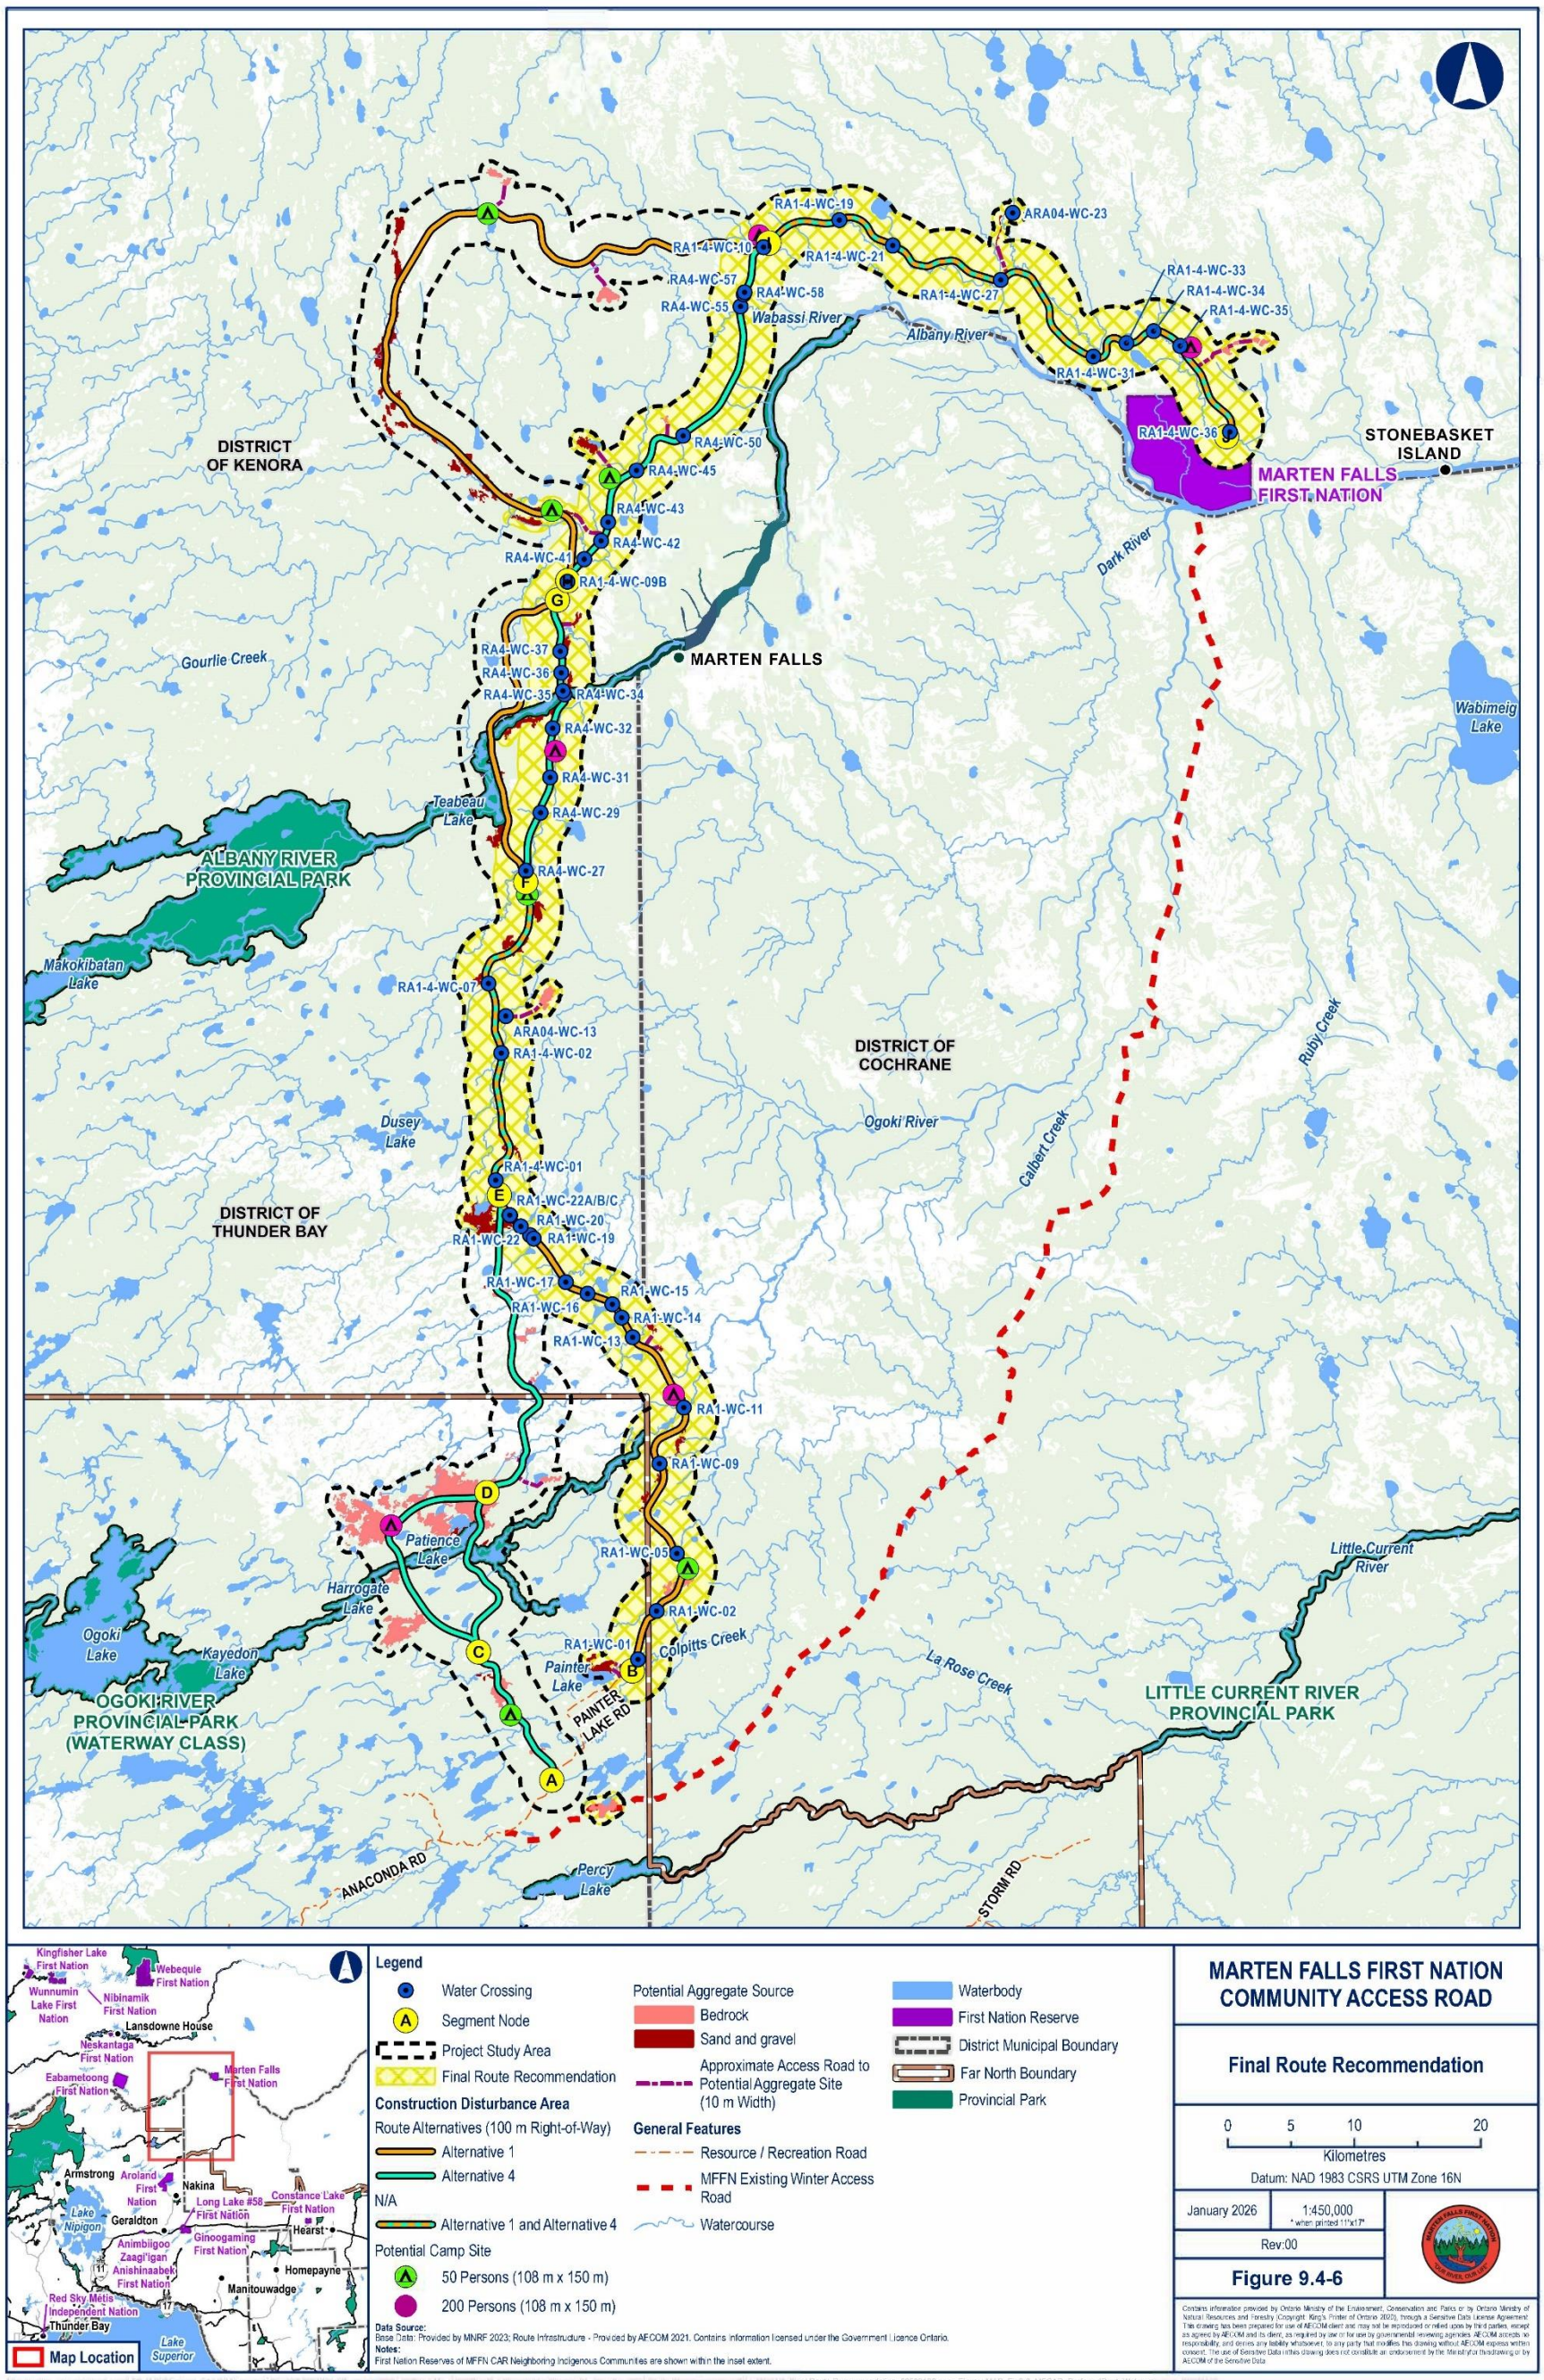
The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Collisions with Vehicles and Equipment

Mitigations will be implemented to minimize effects from collisions with vehicles and equipment reptile and amphibian survival and reproduction in the wildlife effects assessment Local Study Area.

An Environmental Protection Plan will be implemented utilizing the Ministry of Transportation's Environmental Guide for Mitigation Road Impacts to Wildlife (2017b) and includes the following measures to minimize collisions between wildlife and vehicles during construction and operations: provide driver training to Construction workers to understand the importance of reducing vehicle speeds, spread awareness of local wildlife, give wildlife the right-of-way, communicate the presence of wildlife along access roads and on site to

other employees, mandatory reporting of wildlife collisions. Appropriate speed limits will be implemented and enforced. Worker transportation to work sites will be coordinated to reduce traffic volumes. Best management practices and environmental approval conditions, permits, or authorizations issued for the Project will be followed.



During the next phase of the Project, in the Detail Design stage the incorporation of sub-surface eco-passages and exclusion fencing at strategic locations such as culverts, are predicted to partially mitigate the effect of collisions with vehicles and equipment during operations.

At culvert locations along the north-south segment of the Preferred Route (C-01, WA-03, WA-09, WA-12, WA-13, WA-14, and WA-36), modified culverts will be designed to incorporate safe, sub-surface road passage (**Figure 9.4-6**). All culverts along the north–south portion of the Community Access Road have been identified as priority locations for implementing enhanced culvert designs to reduce road mortality risk due to the presence of amphibian breeding habitat, the present of high-suitability common gartersnake habitat, and the higher traffic volume predicted along this segment compared to the east-west segment of the road. However, subsequent Project design and planning phases will consider similar wildlife passage design modifications at all suitable locations.

Culvert design for the incorporation of sub-surface eco-passage will be implemented to provide safe passage for amphibians and reptiles by installing modified box and corrugated steel pipe or arch culverts. Box culverts will be open bottomed with natural substrates, or standard box culverts with floors embedded in natural, local materials. Corrugated steel pipe culverts will consist of open bottom arch culverts or large round culverts with embedded bottoms to be installed to maintain flat, natural substrates through the crossing. Culverts will include a bench attached to the side wall for dry passage during high-water periods; this bench will be positioned above the high-water mark, will connect to ground level at both ends, and will be at least 50 centimetres wide. Modified culverts will have a minimum openness ratio of 0.1 metres opening to length or greater (in other words, 1 m^2 opening: 10 metres culvert length) for sufficient visibility and encourage wildlife movement through the structure. To guide amphibians and reptiles toward these crossings and prevent them from entering the road, permanent exclusion fencing will be installed and maintained in accordance with the Best Management Practices for Mitigating the Effects of Roads on Amphibian and Reptile Species at Risk in Ontario (Ministry of Natural Resources and Forestry, 2016a). Fence lengths will be determined based on site specific habitat conditions.

Using appropriate design and construction techniques has been shown to demonstrate successful implementation of eco passages as a mitigation strategy (Baxter-Gilbert et al., 2015).

Figure 9.4-6 Final Route Recommendation with Water Crossing Locations

9.4.3.3.15.3 Predicted Residual Effects

Habitat Loss and Alteration

A permanent loss of 2,095 hectares of suitable amphibian breeding habitat is expected, representing about 0.6 percent of the total suitable habitat within the effects assessment Regional Study Area. An effect on reptiles of similar extent is expected. The implementation of mitigation and enhancement measures is expected to limit negative effects. However, there are residual effects predicted after implementation of the mitigation measures.

The effect of habitat loss and alteration is considered negative, irreversible, continuous, and certain to occur. The direct effect of habitat loss will be confined to the Construction Disturbance Area. The effects of habitat loss and alteration will result in the fragmentation of contiguous habitat. The effects of fragmentation of habitat are predicted to occur at the scale of the Local Study Area.

After mitigation, the effects from habitat loss and alteration on the ability of reptile and amphibian populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **low** in magnitude.

Sensory Disturbance

Sound, vibration, and light from construction areas cannot be completely mitigated, and some level of sensory disturbance will still be present during construction. Most reptiles and amphibians are not considered to have high sensitivity to sensory disturbances, and the Construction Disturbance Area covers a relatively small percentage of the Local Study Area. However, sensory disturbance could result in decreased mating success for anurans if calling is reduced or degraded by noise disturbance.

There is a predicted residual effect after the implementation of mitigation measures described previously. Reduced reproductive capacity is possible among affected reptiles and amphibians with breeding habitat within the effects assessment wildlife Local Study Area.

The effect is considered negative, local to the wildlife effects assessment Local Study Area, medium-term and reversible during construction, permanent and irreversible during operations, continuous, and probable to occur. After mitigation, the effects from sensory disturbance during construction of the Project on the ability of reptile and amphibian populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

Incidental Take

Mitigation measures will reduce, but likely not eliminate the risk of incidental take of reptiles and amphibians during construction. Effects on mortality will be localized to work areas and transportation corridors and will likely include only a small number of animals.

There is a predicted residual effect after implementation of the mitigation measures.

The effect is considered negative, confined to the Construction Disturbance Area, medium term, infrequent, during construction, and probable to occur. After the implementation of mitigation, the effects from incidental take on the ability of reptile and amphibian populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **low** in magnitude.

Collisions with Vehicles and Equipment

With mitigation, reptile and amphibian mortalities from collisions with vehicles and equipment during construction could be minimized. There is a predicted residual effect after the implementation of mitigation measures described previously.

Implementation of mitigation measures are expected to be effective at minimizing the likelihood of reptile and amphibian collisions with Project vehicles and equipment during construction but are not expected to be as effective during operations because they will be less enforceable amongst public users of the Community Access Road. Because of this, effects are predicted to be probable during construction, irreversible, continuous, and confined to the Construction Disturbance Area. After mitigation, the effects from collisions with vehicles and equipment on the ability of the reptile and amphibian populations in the wildlife effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative but **low** in magnitude.

9.4.3.3.16 Changes to Pollinating Insects

9.4.3.3.16.1 Potential Effects

Habitat Loss and Alteration

<u>Habitat Availability</u>

Although all five insect Species at Risk in the effects assessment Regional Study Area are habitat generalists, changes to habitat will occur during construction. Pollinating insects will directly lose 4,695 hectares of habitat. A conservative assessment has been made by assuming that the entire effects assessment Construction Disturbance Area

(4,700 hectares) is cleared of vegetation. Yellow-banded bumblebees will likely lose underground cavities such as abandoned rodent burrows and decomposing logs that are used for nesting during clearing and grubbing (Committee on the Status of Endangered Wildlife in Canada, 2014a, 2015b, 2019). Since Ashton's cuckoo bumble bees and Suckley's cuckoo bumble bees are parasites on other bumble bee species, including yellow-banded bumble bees, they will also lose nesting habitat with these alterations. A loss of leaf litter in the cleared areas of the effects assessment Construction Disturbance Area will also cause a loss of overwintering habitat for all three bee species as well as both lady beetle species.

Distribution

Habitat loss and alteration during construction will affect the distribution of food resources for insects within the effects assessment Construction Disturbance Area. This will affect the distribution of insects on the local scale. Lady beetles are predators on aphids and can be found on a variety of tree and shrub species (Committee on the Status of Endangered Wildlife in Canada, 2016a, b), whereas bumble bees have varied food preferences for flowering plants. Ashton's cuckoo bumble bee prefers flowering plants located near wooded areas (Committee on the Status of Endangered Wildlife in Canada, 2014a), while the yellow banded bumble bee prefers flowering herbs over shrubs (Gibson et al., 2019), and Suckley's cuckoo bumble bee does not collect pollen and eats nectar from the Asteraceae family (Committee on the Status of Endangered Wildlife in Canada, 2019). All species are dependent on plant habitats for foraging and may prefer to move to the edge of the effects assessment Construction Disturbance Area during construction or forage outside of this area.

Survival and Reproduction

Loss of nesting and overwintering habitat could result in lower survival and reproduction of the populations of pollinating insects within the effects assessment Construction Disturbance Area. Some areas cleared for construction will be allowed to regenerate and will likely provide habitat for pollinating insects (in other words, temporary access, construction camps, and laydown areas).

Sensory Disturbance

Habitat Availability and Survival and Reproduction

Sensory disturbance during construction and operations could result in the indirect loss or degradation of suitable pollinator habitat if individuals avoid areas with sensory disturbance. The effects of noise and artificial light on pollinating insects are unknown. There is inconclusive evidence of whether bumble bees and lady beetles are

considered sensitive to anthropogenic disturbances such as noise and light; however, current scientific understanding suggests that further research on the subject is required.

Incidental Take

Survival and Reproduction

Incidental take of pollinating insects may occur during the Project as a result of either the destruction of individuals or bumblebee nest or bumblebee / beetle overwintering habitats through clearing and grubbing or from collisions with Project vehicles, equipment, or public vehicles using the Community Access Road or associated infrastructure.

During construction, incidental take may lead to mortality in pollinating insects if bumblebee nests or bumblebee / beetle overwintering spots are removed, and when insects are affected by vehicles and equipment. Incidental take may also occur intentionally at construction camps if interactions between Project personnel and stinging insects such as bees require nest removals or killing of bees. This is unlikely to have a measurable effect on insect populations in the wildlife effects assessment Regional Study Area.

Collisions with Vehicles and Equipment

Insects may be killed by collisions with vehicles and equipment during construction. Insects that fly through open areas and edge habitat are particularly at risk. Risks are highest on the Community Access Road corridor as well as temporary access roads when vehicles are travelling to or from work areas. Bumble bee queens in particular are more susceptible to road mortalities when they are searching for nest sites in the spring.

During construction, public transportation on the Community Access Road will not be permitted.

9.4.3.3.16.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

Mitigation measures will be implemented to avoid, minimize, and restore the effects from the Project on pollinating insect habitat availability, distribution, and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

The Project footprint will be limited to the extent feasible. Existing access roads will be used where possible. Decommission and rehabilitate temporary access roads, staging areas, camps, and debris and / or timber stockpiles following construction.

An Environmental Protection Plan and a Cleanup and Rehabilitation Plan will be developed and implemented. Where necessary, seedling planting will occur to improve reclamation success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified. Rehabilitation plans will be confirmed through engagement with Indigenous communities, the Ministry of Natural Resources and local foresters. Effectiveness of reclamation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities. If required, adaptive management will be employed to modify or enhance any reclamation efforts.

Buffer zones of 30 metres will be maintained around waterbodies, clearing of riparian vegetation will be limited to the extent practicable and to the requirement of the access road and alignment clearing width only.

If seeding is necessary for reclamation of temporary construction infrastructure, a native plant seed mix will be used. Roadside ditches / rights-of-way present a mitigation opportunity for native pollinators. Through establishment of appropriate plant communities and implementation of Integrated Vegetation Management, a suitable forage habitat can be maintained while still performing the safety / functionality of rights-of-way (Wojcik and Buchmann, 2012; United States Environmental Protection Agency, 2008).

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Sensory Disturbance

Mitigation measures will be implemented to avoid, minimize, and restore the effects of sensory disturbance on pollinating insect habitat availability, and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

Although bumble bees and lady beetles may not be considered to be sensitive to sensory disturbances, mitigations for sensory disturbance in other valued components may benefit these species.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Incidental Take

Mitigation measures will be implemented to avoid, minimize, and restore the effects of incidental take on pollinating insect and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

Measures taken to avoid incidental take of other valued components, including the implementation of speed limits during construction, will likely decrease the incidental take of insects. Prohibiting the use of chemical insecticides and herbicides is expected to reduce incidental take. Restricting the use of chemical salts for dust suppression will further reduce incidental take.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Collisions with Vehicles and Equipment

Mitigation measures will be implemented to avoid, minimize, and restore the effects of collisions with vehicles and equipment on pollinating insect and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

An Environmental Protection Plan will be implemented utilizing the Ministry's of Transportation's Environmental Guide for Mitigating Road Impacts to Wildlife (2017b) and includes the following measures to minimize collisions between wildlife and vehicles during construction: provide driver training to construction and maintenance workers to understand the importance of reducing vehicle speeds, spread awareness of local wildlife. Appropriate speed limits will be implemented and enforced. Worker transportation to work sites will be coordinated to reduce traffic volumes. Best management practices and environmental approval conditions, permits, or authorizations issued for the Project will be followed.

9.4.3.3.16.3 Predicted Residual Effects

Habitat Loss and Alteration

The Project will result in the removal of 4,700 hectares of mostly undisturbed natural habitat, the majority of which is vegetated and provides suitable nesting, overwintering and foraging resources for pollinating insects. This loss of habitat represents a small

portion of the available habitat within the wildlife effects assessment Regional Study Area. There is a predicted residual effect after the implementation of mitigation measures described previously.

The effect is considered negative, irreversible, continuous, and certain to occur. The direct effect of habitat loss will be confined to the Construction Disturbance Area. The effects of habitat loss and alteration will result in the fragmentation of contiguous habitat. The effects of fragmentation of habitat are predicted to occur at the scale of the Local Study Area.

After mitigation, the effects from habitat loss and alteration on the ability of pollinating insect populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

Sensory Disturbance

Bumble bees are tolerant to sensory disturbances such as sound and light but may be sensitive to artificial electromagnetic fields. Lady beetles are not known to be sensitive to sensory disturbances. This effect is expected to have **no** effect on pollinating insects of concern during construction and operations. No residual effect of sensory disturbance on pollinating insects is predicted.

Incidental Take

Mitigation will reduce but not eliminate incidental take. The population of insects within the Construction Disturbance Area is expected to be a small fraction of the insects within the Local Study Area. There are residual effects predicted after implementation of the mitigation measures.

The effect is considered negative, local to the Construction Disturbance area, medium-term and irreversible during construction, permanent and irreversible during operations, infrequent, and probable to occur. After mitigation, the effects from incidental take on the ability of pollinating insect populations in the wildlife effects assessment Regional Study Area to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

Collisions with Vehicles and Equipment

Insect mortality will occur from collisions with vehicles and equipment during both construction and operations. It is unlikely that a large percentage of the pollinating insects within the effects assessment Regional Study Area will use the Community Access Road and consequently be subject to this risk. There are residual effects predicted after implementation of the mitigation measures.

The effect is considered negative, confined to the Construction Disturbance area, irreversible, continuous, and probable to occur. After mitigation, the effects from collisions with vehicles and equipment on the ability of pollinating insect populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

9.4.3.4 Residual Effects – Operations Phase

9.4.3.4.1 Changes to Wildlife through the Introduction and Spread of Invasive Plant Species

9.4.3.4.1.1 Potential Effects

During operations, regular vehicle traffic on the Community Access Road could transport invasive plant seeds or plant parts into the wildlife effects assessment Local Study Area. Effects from the introduction and spread of invasive plants during operations would be the same as for Construction (see section above). If invasive plant species are introduced and spread within the effects assessment Construction Disturbance Area, this could degrade the quality of habitats used by wildlife, ultimately reducing the availability and distribution of suitable habitat during operations.

9.4.3.4.1.2 Mitigation and Enhancement Measures

A list of mitigation measures to control weeds during operations is provided in the Vegetation Technical Support Document (**Appendix J**) and Peatlands Technical Support Document (**Appendix I**). The effectiveness of mitigation measures will be evaluated during operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.3.4.1.3 Predicted Residual Effects

During construction and operations, invasive plant species may occasionally be introduced within the effects assessment Construction Disturbance Area. Best management practices and mitigation measures for controlling the spread of invasive species are well understood and the methods have been demonstrated to be effective. Should invasive plants be introduced from construction vehicles, the plants will be contained and removed quickly resulting in a small, localized effect in the Construction Disturbance Area that is reversible in the short-term and therefore the effect is not predicted to reduce or degrade wildlife habitat. After implementation of mitigation, effects on wildlife valued components from the introduction of invasive plants during operations are predicted to be reversible over the long term and confined to the effects assessment Construction Disturbance Area. During operations, effects are possible and

infrequent. Effects from the introduction of invasive plants on the ability of the wildlife populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative but **negligible** in magnitude.

9.4.3.4.2 Changes to Wildlife from Emissions of Criteria Air Contaminants

9.4.3.4.2.1 Potential Effects

During operations, emissions would be generated mainly from the use of fossil fuels associated with vehicle use of the Project and road maintenance (general, seasonal, and special maintenance). As discussed in the Atmospheric Environment Technical Support Document (**Appendix S**), air criteria contaminants were predicted to be below Canadian Ambient Air Quality Standards and / or Ontario Ambient Air Quality Criteria thresholds during operations.

9.4.3.4.2.2 Mitigation and Enhancement Measures

A comprehensive list of mitigation measures that will be implemented to limit air particulate emissions during operations is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).

9.4.3.4.2.3 Predicted Residual Effects

As discussed in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I**), emissions of criteria air contaminants are anticipated to have negligible, possible effects on vegetation ecosystems, and, ultimately, wildlife habitat. As such, this interaction was determined to have no residual effects on wildlife habitat availability and distribution and is not carried forward in the assessment.

9.4.3.4.3 Changes to Wildlife from Fugitive Dust Emissions

9.4.3.4.3.1 Potential Effects

Fugitive dust emissions are expected to be produced during operations from activities such as travel on the gravel Community Access Road. Potential effects from fugitive dust emissions on wildlife habitat availability and distribution are outlined in the Construction section above.

During operations, threshold exceedances for the Project are predicted for particulate matter less than 2.5 micrometres, particulate matter less than 10 micrometres and total suspended particulate. The particulate matter less than 2.5 micrometres levels are predicted to reach the 24-hour and annual criteria thresholds at 115 metres and 134 metres from the road, respectively. Levels of particulate matter less than

10 micrometres are predicted to reach the 24-hour threshold at 1,986 metres from the road. Emissions of total suspended particulate total suspended particulate are predicted to reach the 24-hour and annual thresholds at 3,004 metres and 899 metres from the road, respectively.

9.4.3.4.3.2 Mitigation and Enhancement Measures

A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during operations. A comprehensive list of mitigation measures that will be implemented to limit dust deposition during operations is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).

9.4.3.4.3.3 Predicted Residual Effects

Although mitigations will be implemented to reduce dust emissions, dust deposition during operations are predicted to degrade vegetation immediately adjacent to the Project and dust deposition is expected over the life of the Project (long term). There are currently no plans to decommission the Community Access Road, therefore, residual effects are largely irreversible. Effects from dust emissions during operations are predicted to be certain, irreversible, continuous, and confined to the wildlife effects assessment Local Study Area. Effects from dust emissions on the ability of the wildlife populations in the wildlife effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and **negligible** in magnitude.

9.4.3.4.4 Changes to Wildlife from Erosion and Sedimentation

9.4.3.4.4.1 Potential Effects

Erosion and release of sediments in watercourses and adjacent terrestrial habitat may also occur during operations. Large precipitation events may lead to run-off from the road and sedimentation in low lying areas such as wetland and riparian habitats. Similar to construction, the effects would be localized, intermittent and variable.

9.4.3.4.4.2 Mitigation and Enhancement Measures

An environmental monitoring program will be developed and implemented during Maintenance and will contain mitigation measures to control erosion and sedimentation. Similar to Construction, erosion and sediment control measures will be developed and implemented in accordance with Ontario Provincial Standard Specifications for erosion and sediment control measures (OPSS, 2021a and OPSS, 2021b) during Maintenance. Additionally, mitigation identified in the Ministry of Transportation’s Maintenance Quality

Standards and Maintenance Best Practices for highway maintenance (Ministry of Transportation, 2003) will be implemented to minimize erosion and sedimentation during operations. The mitigation measures established and refined using adaptive management during Project Construction should be maintained during operations.

A comprehensive list of mitigation measures that will be implemented during operations is provided in Vegetation Technical Support Document (**Appendix J**) and Surface Water Technical Support Document (**Appendix F**).

9.4.3.4.4.3 Predicted Residual Effects

Environmental protection and monitoring plans developed for operations are expected to limit erosion and sedimentation. After implementing mitigation, the Project is not predicted to result in residual effects on the condition of peatland, upland, wetland and riparian ecosystems (in other words, wildlife habitat), relative to existing conditions (Vegetation Technical Support Document; **Appendix J**). As such, this interaction was not carried forward in the assessment.

9.4.3.4.5 Changes to Wildlife resulting from changes to Surface Water Quantity

9.4.3.4.5.1 Potential Effects

Removal of forested and peatland habitat during Project Construction, and subsequent conversion of treed and peatland habitats to open or shrubby habitats could result in changes to surface water quantity during operations of the Project (Surface Water Technical Support Document; **Appendix F**). Potential effects from changes to surface water quantity on wildlife habitat availability and distribution are discussed in the Construction section, above.

9.4.3.4.5.2 Mitigation and Enhancement Measures

The mitigation measures established and refined using adaptive management during Project Construction should be maintained during operations. Follow Ontario Provincial Standard Specification 411 and regularly inspect and maintain culverts and bridges. Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during operations.

A comprehensive list of mitigation measures to limit changes to surface water quantity during operations is provided in the Surface Water Technical Support Document (**Appendix F**). The effectiveness of mitigation measures will be evaluated during

operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.3.4.5.3 Predicted Residual Effects

Operations of the Project could result in small, localized changes to surface water quantity. After implementing mitigation, changes to surface water quantity are anticipated to be of negligible magnitude. As such, no net residual effects on wildlife habitat availability and distribution are predicted and this interaction was not carried forward in the assessment.

9.4.3.4.6 Changes to Wildlife resulting from Changes in Surface Water Quality

9.4.3.4.6.1 Potential Effects

During operations, mechanical vegetation maintenance activities along the right-of-way could result in changes to surface water quality. For example, organic debris may be transported to nearby waterbodies, which could increase concentrations of suspended solids in the receiving water (Surface Water Technical Support Document; **Appendix F**). This in turn, can affect the quality of wildlife habitat.

9.4.3.4.6.2 Mitigation and Enhancement Measures

During the winter maintenance periods, sand will be used on the Community Access Road for de-icing instead of road salt, as required. Herbicides or pesticides will not be used at any stage of the Community Access Road. Non-chloride containing compounds will be used for dust suppression on the Community Access Road during operations, as required.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during operations. During the winter periods, sand will be used on the Community Access Road for de-icing instead of road salt. Herbicides or pesticides will not be used during operations. The mitigation measures established and refined using adaptive management during Project Construction should be maintained during operations.

A comprehensive list of mitigation measures to limit changes to surface water quality during operations is provided in the Surface Water Technical Support Document (**Appendix F**). The effectiveness of mitigation measures will be evaluated during operations and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.3.4.6.3 Predicted Residual Effects

As described in the Surface Water Technical Support Document (**Appendix F**), Operations of the Project is predicted to result in changes to surface water quality that are negligible in magnitude. As such, no net residual effects on wildlife habitat availability and distribution are predicted and this interaction was not carried forward into the residual effects characterization.

9.4.3.4.7 Changes to Wildlife resulting from Changes to Groundwater

9.4.3.4.7.1 Potential Effects

Effects from changes to groundwater levels on wildlife habitat availability and distribution from the potential settlement of the road base structure and underlying peat material, and from potential sediment accumulation in the road base material restricting the flow of groundwater, will continue through Operations of the Project.

9.4.3.4.7.2 Mitigation and Enhancement Measures

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during operations.

As discussed in the Groundwater Technical Support Document (**Appendix H**), the mitigation measures established and refined using adaptive management during Project Construction should be maintained during operations. It is expected that a robust monitoring program will be undertaken, and adaptive management measures implemented, as required. This monitoring program is described in more detail in the Peatlands Technical Support Document (**Appendix I**).

9.4.3.4.7.3 Predicted Residual Effects

With the implementation of mitigation measures, changes to groundwater regimes will be minimized and impacts to retained vegetation communities and wildlife habitat availability and distribution should be minimal. However, there are still anticipated to be measurable changes to vegetation due to change to groundwater quantity, which are predicted to result in a residual effect on wildlife habitat availability and distribution. As such, this interaction is carried forward to the residual effects characterization.

Pit dewatering and dredging and settlement of the road base structure and underlying peat material or sediment accumulation in the road base material during operations are expected to change groundwater quantity. Effects from changes to groundwater

quantity on wildlife habitat quality are predicted to be **probable, irreversible (long term), continuous,** and confined to **the effects assessment Local Study Area**. Effects from changes to groundwater quantity on the ability of the wildlife populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be **negative** but **negligible in magnitude**.

9.4.3.4.8 Changes to Wildlife from Increase in Wildlife Attractants

9.4.3.4.8.1 Potential Effects

As discussed in the Construction section above, wildlife may be attracted to food smells and waste, petroleum-based chemicals, and roadkill during operations. However, the potential of attracting wildlife from food wastes, petroleum products, and gray water and sewage is expected to decrease during operations once the temporary construction camps are decommissioned.

9.4.3.4.8.2 Mitigation and Enhancement Measures

During Operations, inspections of the road and rest areas will occur two days of each week and, based on these inspections, debris and litter will be collected when detected (Ministry of Transportation, 2003). Additionally, Ontario Ministry of Transportation will remove roadkill when reported by drivers on the highway or when observed during the two-time-per-week highway inspections (Ministry of Transportation, 2003). As per the Ministry of Transportation's Debris Control Maintenance Quality Standard (MQS-331), debris less than one metre in diameter, including roadkill, will be removed within 48 hours; debris greater than one metre in diameter will be removed as detected (Ministry of Transportation, 2003). Generally, roadkill will be removed from the effects assessment Construction Disturbance Area and relocated to adjacent brush areas, as per the Waste and Excess Materials Management Environmental Protection (EP-9) requirements in the Ministry of Transportation's Maintenance Manual (Ministry of Transportation, 2003). As per the Waste and Excess Materials Management Environmental Protection requirements in the Maintenance Manual, depending on the location and weather at the time of roadkill removal, burial of small mammals occur in the roadside ditches, if this activity is permitted under a Certificate of Approval for Waste Management System (Ministry of Transportation, 2003).

Rest areas will be available every 50 kilometres along the road during the operation of the road. The rest areas will be staggered every 25 kilometres, alternating on each side of the highway. These rest areas will contain waste receptacles. As per the Ministry of Transportation's Rest Area/Picnic Site Maintenance Best Practice (MBP-325), during the rest areas operating season (in other words, months during the year when temperatures remain above 0°C and closing no sooner than October 15), litter in waste

receptacles will be removed from rest areas when waste receptacles are 75 percent full (Ministry of Transportation, 2003).

9.4.3.4.8.3 Predicted Residual Effects

Human activity during operations may increase wildlife attractants (smells, garbage, food) in the effects assessment Construction Disturbance Area. Mitigation should limit wildlife attractants and attraction of predators that may use valued components as a prey resource to the Project. However, there is potential that carnivores, including wildlife valued components, may be attracted to the Project during construction and operations, which may affect predator-prey relationships. Effects are predicted to be possible, irreversible, continuous, and confined to the effects assessment Construction Disturbance Area. Effects from wildlife attractants and changes to predator-prey relationships on the ability of wildlife populations within the effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude.

9.4.3.4.9 Changes to Wildlife from Blasting and Associated Fly Rock

9.4.3.4.9.1 Potential Effects

Explosives may be used at quarry sites to excavate materials to be used for maintenance of the Community Access Road. Blasting activities may produce fly rock that has the potential to strike wildlife in the vicinity and cause injury or death. The risk of mortality from being struck by fly rock would be greatest for wildlife who occupy territories that overlap blasting sites. Blasting will be infrequent during operations, and the risk of mortality to wildlife from fly rock is anticipated to be much lower during operations relative to Construction.

The potential effects on wildlife from the sensory disturbances associated with blasting during operations are addressed separately under Sensory Disturbance.

9.4.3.4.9.2 Mitigation and Enhancement Measures

A comprehensive list of mitigation measures that will be implemented during operations is provided in Acoustic and Vibration Technical Support Document (Appendix P).

During Operations, quarry blasting will be suspended within 4 km of known or potential wolverine denning areas during the denning period to minimize sensory disturbances (January 15 to May 31).

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry

of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources, will be followed during operations.

9.4.3.4.9.3 Predicted Residual Effects

Due to the infrequent timing of blasting, and with the implementation of mitigation, blasting and fly rock from the Project during operations is not expected to result in injury or mortality of wildlife. There is no residual effect predicted for this Project–environment interaction on wildlife survival and reproduction. Therefore, this interaction was not carried forward in the assessment.

9.4.3.4.10 Changes to Wildlife from Chemical or Hazardous Material Spills

9.4.3.4.10.1 Potential Effects

There is the potential for accidental spills of fuels and other materials from vehicles and vehicle collisions during operation of the Preferred Route during the operation phase and from malfunctions of equipment or spills during equipment or vehicle refuelling during Maintenance of the Preferred Route activities. Effects from spills on water, soil, and vegetation quality during the operation phase are the same as discussed in the construction section.

9.4.3.4.10.2 Mitigation and Enhancement Measures

Mitigation measures described in the Surface Water Technical Support Document (**Appendix F**), Groundwater Technical Support Document (**Appendix H**), Physiography, Terrain, and Soils Technical Support Document (**Appendix N**), and Vegetation Technical Support Document (Appendix J) will be implemented to minimize effects from chemical and hazardous material spills in the wildlife effects assessment Local Study Area during operations.

Mitigations during operations include adherence to federal and provincial regulations and guidelines regarding fuel and residue, chemical product, petroleum product, and hazardous substance collection and storage, use and handling, and disposal and treatment, such as the federal *Transportation of Dangerous Goods Act*, the Ontario *Dangerous Goods Transportation Act*, and the Ontario Environment Act. Maintenance owner / operators will receive similar training as Construction owner / operator, described above.

During Operations, mitigations will include a posting and enforcement of a speed limit on the highway, which should reduce potential for chemical or hazardous material spills by reducing vehicle collision risk.

9.4.3.4.10.3 Predicted Residual Effects

Effective implementation of the mitigation measures described previously are anticipated to minimize the frequency, spatial extent, and severity of spills. Effects on wildlife from spills in the Project footprint are anticipated to be unlikely due to the implementation of the mitigation measures and are not expected to result in measurable environmental changes and were determined to have no residual effect on wildlife survival and reproduction. Therefore, this potential effect (chemical or hazardous material stored on the Project footprint, or spills can adversely affect wildlife survival and reproduction) is not carried forward to the residual effects characterization.

9.4.3.4.11 Changes to Bats (Little Brown Myotis and Northern Myotis)

9.4.3.4.11.1 Potential Effects

Habitat Loss and Alteration

Habitat Availability

Although habitat will be initially removed during construction, the effects on little brown myotis and northern myotis habitat availability from habitat loss will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Distribution

Although habitat will be initially removed during construction, the effects on little brown myotis and northern myotis distribution from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Survival and Reproduction

Although habitat will be initially removed during construction, the effects on little brown myotis and northern myotis distribution from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Sensory Disturbance

Habitat Availability

The effects of sensory disturbance on bats will be greater during operations because traffic will not be restricted to daylight hours. Sensory disturbance during operations may be related to vehicular traffic on the Community Access Road as the produced

noise can impair echolocation efficiency (Finch et al., 2020; Schaub et al., 2008; Siemers and Schaub, 2011). Sensory disturbance will occur along the entire length of the Community Access Road and will occur at any time of day or night during operations.

Bat activity may decrease across the Construction Disturbance Area and in proximity to it as a result of sensory disturbance during operations (Kitzes and Merenlender, 2014). Bats have been noted to have decreased activity across roads, they can act as a barrier and restrict bats from accessing critical resources (Claireau et al., 2019; Kitzes and Merenlender, 2014; Pauli et al., 2017).

During Operations, noise is predicted to reach 50 A-weighted decibels at 100 metres from the edge of the effects assessment Construction Disturbance Area (Acoustic and Vibration Environment Technical Support Document [Appendix P]). Although A-weighted decibels measure the loudness of sounds as perceived by the human ear (audible range), and bats hearing is more sensitive at higher frequencies, bats are known to avoid foraging in proximity to noise disturbance including roads.

As a precise threshold of avoidance by little brown myotis and northern myotis is not known, habitat that was within 100 metres of the Project was assumed to be negatively affected by sensory disturbance as a precautionary approach. The effects of sensory disturbance on bats are predicted to be greatest during foraging, and all terrestrial, wetland and open water habitats may provide foraging habitat (Environment Canada, 2015). Therefore, the areas of bat habitat that may be indirectly affected by sensory disturbance include all areas within 100 metres of the effects assessment Construction Disturbance Area. A total of 236 hectares of potential bat foraging habitat may be indirectly affected within 100 metres of the effects assessment Construction Disturbance Area. This represents 0.16 percent and 0.05 percent of the effects assessment Local Study Area and effects assessment Regional Study Area, respectively.

Survival and Reproduction

During Operations, noise is predicted to reach 50 A-weighted decibels at 100 metres from the edge of the effects assessment Construction Disturbance Area (Acoustic and Vibration Environment Technical Support Document [Appendix P]). Sensory disturbance can occur along the entire length of the Community Access Road and can occur at any time of day or night during operations. Although sensory disturbance from traffic may result in periodic changes to bat foraging behaviour, it is unlikely to have a measurable effect on bat survival and reproduction due to the abundance of unaffected bat foraging habitat available in the wildlife effects assessment Regional Study Area.

Incidental Take

Survival and Reproduction

During operations, incidental take of bats is unlikely, but may occur if mature trees are removed for maintenance activities during the roosting period.

Collisions with Vehicles and Equipment

Bat mortalities from collisions with vehicles and equipment are most likely to happen during operations when public vehicles are travelling along the Community Access Road. Areas where canopy heights adjacent to the road are lower may have a higher risk of bat mortality due to bats flying lower to the ground (Russell et al., 2009).

A total of 700 vehicles per day have been modelled to be using the north-south (to the Ring-of-Fire) segment of the Project, and 100 vehicles per day have been modelled to be using the east-west segment (to Marten Falls First Nation) (Appendix W). Most vehicular traffic on the north-south segment of the Project will be medium and heavy truck usage, consisting of 71 percent of traffic (AECOM, 2024). Most traffic on the east-west section of the Project is expected to be light vehicle traffic (77 percent of all traffic) (AECOM, 2024). The increase in Project-related traffic during operations, may increase the number of bat-vehicle collisions relative to existing conditions.

9.4.3.4.11.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

A Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed to counterbalance little brown myotis and northern myotis habitat loss. As the Preliminary Biodiversity Offset Plan is further developed, it is anticipated that artificial bat roost structures will be installed within temporary disturbance areas and in appropriate areas within the effects assessment Local Study Area to mitigate the removal of tree roosts for little brown myotis and northern myotis. During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Preliminary Biodiversity Offset Plan, cleanup and reclamation plans, and the protocol/system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

Sensory Disturbance

Mitigations will be implemented to minimize effects from sensory disturbance on little brown myotis and northern myotis habitat availability and survival and reproduction in the wildlife effects assessment Local Study Area during operations. The effectiveness of mitigation measures will be evaluated, and mitigation measures will be modified or enhanced as necessary through adaptive management.

During Operations, work will be completed as quickly as possible to reduce the duration of disturbance associated with maintenance activities. The Environmental Protection Plan will be implemented to minimize sensory disturbance by owner / operator, including prohibiting use of engine retarder brakes, enforcing speed limits, and restricting maintenance traffic to designated areas. Ongoing use of inactive areas will be prevented through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Preliminary Biodiversity Offset Plan, cleanup and reclamation plans, and the protocol/system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

Mitigations to reduce sensory disturbance by the general public during operations are difficult to enforce; however, speed limits may reduce noise associated with vehicle traffic. Owner / operator employed to conduct maintenance activities will follow the same mitigations as outlined for construction.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources, will be followed during construction and operations.

A Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed to achieve a net positive outcome for little brown myotis and northern myotis habitat. Over the long term, measures undertaken as part of the Preliminary Biodiversity Offset Plan would be implemented to achieve a net increase in functional bat habitat relative to existing conditions.

Incidental Take

Mitigation measures described above will be applied during operations as required. During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Preliminary Biodiversity Offset Plan, cleanup and reclamation plans, and the protocol/system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

Collisions with Vehicles and Equipment

Collision risk during operations will be minimized with implementation of the Environmental Protection Plan, which includes measures to minimize collisions between wildlife and vehicles. Speed limits will be posted and enforced to reduce vehicle speeds and associated collisions with wildlife.

Signage will be posted where the road crosses the Albany River and Ogoki River (important bat flyways) to notify motorists of the elevated risk of collisions with bats in these areas at night between May and November to encourage reduced travel speeds during that time.

During Operations, the ongoing use of inactive areas by the public will be minimized through physical control measures such as rollback, removal of creek crossings, felling of timber across temporary access roads, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access. Progressive reclamation and revegetation will be implemented as non-permanent features will be decommissioned and reclaimed or revegetated naturally.

During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Biodiversity Offset Plan, cleanup and reclamation plans, and the protocol/system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

Mitigations will be implemented to minimize effects from collisions with vehicles and equipment on little brown myotis and northern myotis survival and reproduction in the wildlife effects assessment Local Study Area during operations.

9.4.3.4.11.3 Predicted Residual Effects

Habitat Loss and Alteration

Suitable roosting habitat within the effects assessment Local and Regional Study Area will be reduced by roughly 694 hectares which corresponds to an 11.81 percent loss and 2.59 percent loss of the available suitable habitat in the respective study areas. Habitat within temporary Construction Disturbance Areas will regenerate and / or be restored after construction; however, mature forest stands recover slowly, making this habitat unsuitable for bat maternity roosting for up to 80 years (Ministry of Natural Resources and Forestry, 2017). Habitat fragmentation may permanently alter foraging around the Community Access Road during operations.

The mitigation measures proposed are anticipated to reduce potential mortality due to clearing and grubbing of suitable roosting habitat to negligible levels.

There is a predicted residual effect of habitat loss after implementation of the mitigation measures described previously. The effect (reduced maternity roost habitat from loss or alteration of vegetation) is carried forward to the characterization of predicted residual effects.

The effect is considered negative, irreversible, continuous, and certain to occur. The direct effect of habitat loss will be confined to the Construction Disturbance Area. The effects of habitat loss and alteration will result in the fragmentation of contiguous habitat. The effects of fragmentation of habitat are predicted to occur at the scale of the Local Study Area.

Effects from habitat loss and alteration on the ability of little brown myotis and northern myotis populations in the wildlife Regional Study Area to remain self-sustaining and ecologically functional are predicted to be **low** in magnitude.

Sensory Disturbance

Sensory disturbance is probable during construction, though mitigation through identifying roosting areas and limiting noise production will reduce this. Bats are moderately tolerant to sensory disturbance but may avoid the Project area during construction and operations. The effects of sensory disturbance are expected to be permanent and irreversible during operations, continuous, probable, and limited to a local scale. Effects from sensory disturbance on the ability of little brown myotis and

northern myotis populations in the wildlife effects assessment Regional Study Area to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

Incidental Take

Mitigation measures, polices, and practices for construction activities are expected to avoid and limit incidental take of roosting bats relative to existing conditions. However, these measures are not anticipated to eliminate the risk of incidental take, there are residual effects predicted after implementation of the mitigation measures.

The mitigation measures for construction activities are expected to avoid and limit incidental take of roosting or hibernating bats. Effects from incidental take on the ability of bat populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

Collisions with Vehicles and Equipment

The implementation of mitigation is anticipated to limit Project-related changes to the survival and reproduction of bats from increased collision risk with vehicles and equipment. A limited number of bat mortalities during operations may occur. As such, there is a predicted residual effect after the implementation of mitigation measures described previously.

Effects are predicted to be possible, irreversible, continuous, and confined to the Construction Disturbance Area. Effects from collisions with vehicles and equipment on the ability of the little brown myotis and northern myotis populations in the wildlife effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be negative but **negligible** in magnitude.

9.4.3.4.12 Changes to Furbearers (Wolverine)

9.4.3.4.12.1 Potential Effects

Habitat Loss and Alteration

<u>Habitat Availability</u>

Although habitat will be initially removed during construction, the effects on wolverine survival and reproduction from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

During Operations, temporary construction infrastructure will be allowed to regenerate. Newly regenerating forest stands are likely to provide good habitat for wolverines for foraging. However, wolverines may avoid denning areas within 4 km of an active road (Scrafford et al., 2018, Scrafford and Ray, 2022). Alteration of habitat due to road effects may make high-quality denning habitat within 4 km of the Project unsuitable for use as denning areas. A total of 189,145 hectares are within 4 km of the Construction Disturbance area. Suitable denning habitat within this area may be indirectly affected because of habitat alteration due to a road effects.

Habitat within the effects assessment Construction Disturbance Area is conservatively assumed to be permanently removed from the available habitat for wolverines. Loss of habitat through fragmentation, which begins in construction and continues through operation and will most likely be worse when high road traffic volumes occur.

Distribution

Although habitat will be initially removed during construction, the effects on wolverine habitat distribution from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated). Effects on wolverine distribution may occur due to the tendency of females to avoid establishing natal dens in proximity to roads. Denning areas previously used by females may be completely or partially abandoned due to the road effects on denning habitat. This effect may occur up to a distance of approximately 4 km from the Construction Disturbance Area (Scrafford and Ray, 2022).

Survival and Reproduction

Although habitat will be initially removed during construction, the effects on wolverine survival and reproduction from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Changes to abundance associated with habitat loss during operations are likely to include the continued loss of denning habitat within the corridor, and indirect effects on suitable denning habitat within 4 km of the Construction Disturbance Area through road effects. Denning areas previously used by females may be completely or partially abandoned. Road effects may result in females avoiding high-quality denning habitat in favour of lower quality habitat located further from the road, which could affect reproductive success. Additional habitat loss may occur if denning habitat is removed during maintenance, such as during additional clearing within the corridor. This effect is unlikely as wolverines do not typically construct dens near roads (Scrafford et al., 2018).

The habitat fragmentation caused by the Project may decrease population connectivity which could result in genetic isolation and demographic fragmentation (Sawaya et al., 2019).

Habitat loss and alteration may also affect wolverine survival and reproduction through changes to food resources. Ungulates are an important food resource for wolverines for much of the year, and ungulate species (in other words, caribou and moose) in the effects assessment Regional Study Area are also noted to be sensitive to both sensory disturbance and anthropogenic linear features. There may be areas modified during the Project where additional non-animal forage, such as berries that grow well in disturbed environments and edge habitat, may become more abundant. Foraging in the edges of cleared habitat, such as aggregate pits and newly regenerating forest, has been documented (Scrafford et al., 2017). Shifts from higher quality to lower quality food resources in the wolverine effects assessment Local Study Area resulting in changes to ungulate distribution may affect the energy budget of wolverines, particularly those with home ranges close to the Project. This may influence mortality and reproductive success.

Sensory Disturbance

Habitat Availability

Sensory disturbance may also modify wolverine habitat use within the wolverine effects assessment Local Study Area during operations. Maintenance activities will have an effect on the noise levels in the effects assessment Construction Disturbance Area, and traffic from road use may also disturb wolverines near the road right-of-way (Sawaya et al., 2019).

Noise modelling indicates that vehicle traffic on the Community Access Road during operations will result in noise levels ranging from 41 to 53 A-weighted decibels at the edge of the effects assessment Construction Disturbance Area. Noise levels at 500 metres from the effects assessment Construction Disturbance Area are predicted to range between 38 and 41 A-weighted decibels, which are below the daytime level of 45 A-weighted decibels that is typical of rural and remote areas, as described in the Guidance for Evaluating Human Health Effects in Impact Assessment: Noise (Health Canada, 2023). In addition, ground vibrations induced by vehicle traffic during operations are predicted to be negligible beyond 25 metres of the right-of-way of the Community Access Road (Acoustic and Vibration Technical Support Document [**Appendix P**]).

Wolverines are known to avoid constructing dens near active roads. In the Red Lake area of Ontario, den sites were observed at an average of 1 kilometres from smaller

industrial roads and 4.8 kilometres from major roads (Scrafford and Ray, 2022). Maintenance activities will be short-to-medium term disturbances that happen repeatedly during the operation of the Community Access Road, while traffic will be a continuous source of sensory disturbance.

Sensory disturbance of varying levels can occur along the entire length of the Community Access Road and can occur at any time of day during operations.

Distribution

Animals may remain sensitive to the presence of people and vehicles on the Community Access Road during operations (Leblond et al., 2013). During operations, sensory disturbance will mostly be produced by road use and maintenance activities. During Operations, an Average Annual Daily Traffic of 700 vehicles on the north-south section and 100 vehicles on the east-west section is anticipated by 2046. An estimated 64 percent of the traffic on the north-south segment and 3 percent of the traffic on the east-west segment of the Community Access Road is anticipated to be heavy trucks (in other words, vehicles with three or more axles designed for transportation of cargo), which will create more sensory disturbance than light-duty and medium trucks used for personal and business use. No mining trucks are anticipated to use the east-west segment of the Community Access Road; however, the east-west segment may have commercial truck traffic accessing the aggregate facilities near the community for maintenance of the road. Although there may be periods with long intervals between vehicles along one location on the Community Access Road (infrequent disturbance), during other periods vehicles may be using the road through the day and night and the interval between vehicles would be relatively shorter resulting in frequent to continuous sensory disturbance.

The continued operation of quarries during Operations is predicted to emit noise levels between 55 and 77 A-weighted decibels at the edge of the effects assessment Construction Disturbance Area (Acoustic and Vibration Technical Support Document [Appendix P]). Existing vibration levels are expected to increase, on occasion, due to quarry blasting activities but blast-induced vibration will be temporary in nature, occur only during specific activities, and would be limited to the vicinity of Project quarries. Ground vibration from occasional quarry blasting during operations is expected to produce a short-term increase in ground vibration and air overpressure within the vicinity of a blast source (Acoustic and Vibration Technical Support Document [**Appendix P**]).

As such, the effect of sensory disturbance during operations from maintenance activities and traffic are anticipated to have an ongoing effect on wolverine behaviours, such as dispersal and avoidance of human activities.

Survival and Reproduction

A long-term change in otherwise good quality denning habitat due to sensory disturbance is also likely to occur. During operations, wolverines may avoid denning near the Community Access Road (Scrafford et al., 2018) and may experience a loss of denning habitat greater than the direct habitat loss from the Project. Less available denning habitat within home ranges that overlap or are in proximity to the Project may decrease the reproductive output of the population and lead to changes in abundance. Sensory disturbance from roads may also create a partial barrier to dispersal and foraging, which may also influence abundance. Changes to foraging behaviour and increased movement speed near roads has also been documented (Scrafford et al., 2018), either of these effects may induce stress and increase energy expenditure, influencing mortality or the reproductive output of animals in the wolverine effects assessment Regional Study Area.

During Operations, sensory disturbance will decrease, and it is anticipated that species will adapt and prey species such as ungulates may return to the areas surrounding the effects assessment Construction Disturbance Area. Edge habitat maintained along the corridor may be used by wolverines to hunt some smaller prey and forage for non-animal food resources. Sensory disturbance may still reduce ungulate use of the area, and the presence of the anthropogenic linear feature may further reduce the quality of habitat for prey resources.

Increase in Predator Access

Distribution

Although effects on the distribution of wolverine will initially occur during construction, the effects on wolverine distribution will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Survival and Reproduction

Some species that wolverines may have competitive interactions with are anticipated to benefit from anthropogenic linear features such as roads, particularly during times when traffic is light. Coyotes and grey wolves may travel along the corridor during operations and may interact competitively with wolverines. Once constructed, the Community Access Road is expected to have a sufficient amount of vehicle traffic that predators would likely not or infrequently use the road right-of-way for travel except during periods

when traffic is light. However, during operations, predators are more likely to travel along access roads that have been decommissioned and have limited human activity because they will be naturally revegetating and may attract moose and deer; animals that select early seral vegetation for browse (McLoughin et al. 2019; Kautz et al. 2021). Additionally, wolves and black bears may exploit wolverines as a prey resource (Ontario Wolverine Recovery Team, 2013). As a result, the increase in linear features due to the Project could improve predator mobility and increase encounter rates between predators and wolverine in the wolverine effects assessment Local Study Area.

While there is anticipated to be an increase in competition for food resources, increased movement of wolves and other predators along the Project corridor and access roads may lead to an increase in available food resources for wolverines that are known to scavenge carrion.

Incidental Take

Incidental take from maintenance operations is unlikely to occur during operations because wolverines are not known to build dens near roads (Ontario Wolverine Recovery Team, 2013).

Collisions with Vehicles and Equipment

During Operations, traffic volumes are expected to be greatest on the north-south section of the Community Access Road compared to the east-west section that connects to the Marten Falls First Nation. Specifically, the predicted average annual daily traffic volumes are 700 vehicles on the north-south section and 100 vehicles on the east-west section (Appendix W). Heavy trucks will make up over half (64 percent) of the traffic on the north-south section while the traffic on the east-west section will consists of 3 percent heavy trucks and the remaining as light-duty vehicles and medium-size trucks. Traffic volumes are expected to vary temporally and spatially, with a greater volume occurring in the south compared to northernmost portions of the Community Access Road where human density is lower. As a result, most of the wolverine-vehicle collisions that may occur during operations are likely to be attributed to collisions with public and industry vehicles that are not associated with the Project.

Vehicle collisions with wolverines are most likely during operations during the anticipated average daily traffic volumes on the Community Access Road occur and traffic speed limits cannot be easily enforced. Normal road operation may carry a greater risk than maintenance as sensory disturbance will likely be lower, and vehicles may be moving at a higher speed. Young dispersing males may be particularly vulnerable to mortality from collisions with vehicles (Ontario Wolverine Recovery Team, 2013). Due to the low density of wolverines in the effects assessment Regional Study

Area, and the species' low reproductive rate, mortality of even a small number of females may negatively affect the regional population (Scrafford and Ray, 2022; Scrafford et al., 2024). Wolverines may also be attracted to new disturbances as potential foraging opportunities, which may increase the possibility of road mortalities during early operations (Scrafford et al., 2017). This effect will be permanent, though it may have a lower magnitude than in other study areas as the road density following construction will be lower than that of other studies, such as the Red Lake study (Scrafford et al., 2021).

Increase in Public Access

Trapping has a notable effect on the sustainability of wolverine populations (Ontario Wolverine Recovery Team, 2013). There are ten trap lines overlapping the Local Study Area. Increase in public access to the corridor during operations may cause a corresponding increase in trapping pressure on the wolverine population. Wolverine mortalities and injuries have been demonstrated to occur due to incidental catch during fur trapping (Scrafford et al., 2024; Ontario Wolverine Recovery Team, 2013). Although non-indigenous trappers are prohibited from targeting wolverine in Ontario, an unknown number of wolverines are harvested incidentally each year (Scrafford et al., 2024).

The potential increase in trapping and the corresponding increase in wolverine mortality within the wolverine effects assessment Local and Regional Study Area resulting from the increase in public access is not possible to predict because fur market prices influence efforts expended on trapping (Ontario Wolverine Recovery Team, 2013).

9.4.3.4.12.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources, will be followed during operations. During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Biodiversity Offset Plan, cleanup and reclamation plans, and the protocol/system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

The effectiveness of mitigation measures will be evaluated during operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Sensory Disturbance

Mitigation measures will be implemented to minimize effects from sensory disturbance on wolverine habitat availability, distribution, and survival and reproduction in the wildlife effects assessment Local Study Area during operations. The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

During Operations, work will be completed as quickly as possible to reduce the duration of disturbance associated with maintenance activities. The Environmental Protection Plan will be implemented to minimize sensory disturbance by owner / operators, including prohibiting use of engine retarder brakes, enforcing speed limits, and restricting maintenance traffic to designated areas. Ongoing use of inactive areas will be prevented through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Preliminary Biodiversity Offset Plan (**Appendix AB**), cleanup and reclamation plans, and the protocol / system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

During operations, quarry operations will occur periodically. If any periodic quarry operations planned to occur during the denning period, these activities will be preceded by wolverine den surveys conducted within 4 km of quarry operations. Quarry operations will not be conducted within 4 km of active wolverine dens during the denning period.

Mitigations to reduce sensory disturbance by the general public during operations are difficult to enforce; however, speed limits will be posted and enforced to reduce vehicle speeds and associated noise and dust emission levels.

Increase in Predator Access

To minimize ongoing attraction of predators to the Project area, road kill will be cleaned up following best management practices outlined by Ontario's Ministry of Transportation and wildlife access to waste will be restricted. The ongoing use of inactive areas by predators will be minimized through physical control measures such as rollback, removal of creek crossings, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access. During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Biodiversity Offset Plan, cleanup and reclamation plans, and the protocol/system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

Incidental Take

During operations, any periodic blasting will be completed outside of the denning period. Mitigation measures described above will be applied during operations as required. During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Preliminary Biodiversity Offset Plan (**Appendix AB**), cleanup and reclamation plans, and the protocol/system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

Collisions with Vehicles and Equipment

During Operations traffic will be restricted to approved right-of-way, workspace, and access roads or trails. Pits and quarries and other infrastructure required for maintenance activities will be gated to limit public access. A reporting protocol and system to report incidental wildlife observations and wildlife-vehicle collisions during operations will be developed. Appropriate speed limits, wildlife crossing, and wildlife warning signage will be posted. Speed limits will be implemented and enforced. During highway maintenance, Ministry of Transportation's Best Management Practices for

Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Preliminary Biodiversity Offset Plan (**Appendix AB**), cleanup and reclamation plans, and the protocol/system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

The effectiveness of mitigation measures will be evaluated during construction, Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Increase in Public Access

During Operations, the Community Access Road will be accessible to the public but access roads for aggregate areas and other infrastructure required for maintenance activities will be gated to limit public access. Employees will be prohibited from hunting or carrying firearms while working on the Project maintenance. During highway maintenance, Ministry of Transportation's Best Management Practices for Species at Risk Protection During Maintenance Activities (Ministry of Transportation, 2017a) will be considered and included in the development of the Environmental Protection Plan.

The Environmental Protection Plan, Preliminary Biodiversity Offset Plan (**Appendix AB**), cleanup and reclamation plans, and the protocol / system for reporting incidental wildlife interactions and collisions will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and the Ministry of the Environment, Conservation, and Parks Species at Risk Branch.

A proactive outreach and education program aimed at increasing awareness of the presence of wolverine within the area, the potential effects of incidental trapping on wolverine populations, and effective mitigation measures that reduce the likelihood of incidental wolverine trapped as outlined in Best Management Practices to Avoid Wolverine (Ontario Fur Managers Federation, 2018) will be developed and implemented.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.3.4.12.3 Predicted Residual Effects

Habitat Loss and Alteration

The implementation of mitigation measures described above are expected to limit negative effects from habitat loss and alteration on this species in the wolverine effects assessment Local and Regional Study Areas. Wolverine will directly lose 4,700 hectares of habitat. The total direct loss of habitat is much smaller than a single female wolverine home range. However, due to the linear distribution of the disturbance and the fact that wolverines have large home ranges and high daily movement rates, a large portion of the regional population will be affected by habitat loss and alteration resulting from the Project. While the loss of habitat in the wolverine Local Study Area has the potential to affect the home ranges of local individuals, wolverine occupying the wolverine effects assessment Regional Study Area, will still have an amount of undisturbed habitat that remains intact and is anticipated to support a self-sustaining and ecologically functional population.

There are residual effects predicted after implementation of the mitigation measures. After mitigation, the Project is expected to result in a net residual effect on wolverine habitat availability, distribution and survival and reproduction from habitat loss and alteration associated with operations. Therefore, the potential effect of habitat loss and alteration is carried forward in the assessment.

Effects of habitat loss and alteration are predicted to be certain, irreversible, and continuous. The direct effect of habitat loss will be confined to the Construction Disturbance Area. The effects of habitat loss and alteration will result in the fragmentation of contiguous habitat. The effects of fragmentation of habitat are predicted to occur at the scale of the effects assessment Local Study Area.

Effects from habitat loss and alteration on the ability of the wolverine population in the effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be **negative** and **moderate** in magnitude.

Sensory Disturbance

Road traffic will cause sensory disturbance to wolverines indefinitely during operations.

Large prey species may move away from the Community Access Road within the effects assessment Regional Study area due to sensory disturbances and changes in the movement of predators. Residual effects, with the exception of changes in the distribution of ungulate prey resources, are expected to be localized to the area surrounding the effects assessment Construction Disturbance Area. There are residual effects predicted after implementation of the mitigation measures.

Effects from habitat sensory disturbance on the ability of the wolverine populations in the wolverine effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be **negative** and **low** in magnitude.

Increase in Predator Access

Mitigation, particularly of temporary access roads, will reduce but not eliminate the potential for the Project to cause adverse interactions between wolverines and other predatory wildlife. The permanent road will provide a corridor that may be used by wolves and coyotes to occupy areas where they would be competing with wolverines. As mesopredators, coyotes may have a measurable effect on the availability of food for wolverines. Both wolves and coyotes may alter the distribution of prey resources around the effects assessment Construction Disturbance Area. Changes to the movement of wolves and coyotes are expected to decline with distance from the Community Access Road, with the highest level of effect immediately surrounding the Construction Disturbance Area. There are residual effects predicted after implementation of the mitigation measures.

Effects on wolverine survival and reproduction from increased predator access are predicted to be possible, continuous, permanent (permanent access roads) or long term (decommissioned and revegetated access roads) and will be confined to the wolverine effects assessment Local Study Area. Considering that the Project will result in a very small increase in linear feature density in the wolverine effects assessment Regional Study Area (0.04 kilometres per square kilometre), and linear corridors will remain absent or limited in most of the wolverine effects assessment Regional Study Area, effects from increased predator access on the ability of the wolverine population to remain self-sustaining and ecologically functional are anticipated to be negative and **negligible** in magnitude.

Incidental Take

Incidental take from destroying or disturbing dens is not expected to occur during operations.

After mitigation, effects of incidental take are predicted to be possible, medium term and irreversible, infrequent, and confined to the Construction Disturbance Area. Effects from incidental take on the ability of wolverine in the wolverine effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative but **low** in magnitude.

Collisions with Vehicles and Equipment

During operations, road collisions will likely be a source of mortality for wolverines. Vehicle collisions are a potentially persistent source of mortality for wolverines (Krebs and Lewis, 1999; Krebs et al., 2004). As relatively large carnivores with very low reproductive rates and large home ranges, wolverines are expected to be particularly sensitive to road mortality (Rytwinski and Fahrig, 2011). Due to the low density of wolverines in the effects assessment Regional Study Area, and the low reproductive potential of wolverines, mortality of even a small number of females may have negative effects on wolverine survival and reproduction. There are residual effects predicted after implementation of the mitigation measures.

The effects of collisions with vehicles and equipment are predicted to be possible, continuous, permanent and irreversible, and confined to the effects assessment Construction Disturbance Area. After mitigation, the effects from collisions with vehicles and equipment on the ability of the wolverine populations in the wildlife effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative and **moderate** in magnitude.

Increase in Public Access

The Project is expected to result in a measurable increase in public access and trapping opportunities for Indigenous and non-Indigenous trappers in the wolverine effects assessment Local Study Area during operations relative to existing conditions. Closure of temporary access roads will help mitigate the effect of increased public access on trapping mortality. Public access will remain increased in areas near the Community Access Road and temporary infrastructure may still provide increased access to people travelling on foot or by all-terrain vehicle, even with the entrances blocked. Any increase in wolverine trapping effort may have a measurable effect on wolverine survival and reproduction. There are residual effects predicted after implementation of the mitigation measures.

The effects of increase in public access are predicted to be possible, continuous, irreversible, and confined to the wildlife effects assessment Local Study Area. After mitigation, the effects from Increase in Public Access on the ability of the wolverine population in the wolverine effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative but **low** in magnitude.

9.4.3.4.13 Changes to Furbearers (American Marten)

9.4.3.4.13.1 Potential Effects

Habitat Loss and Alteration

Habitat Availability

Although habitat will be initially removed during construction, the effects on American marten habitat availability from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the Community Access Road, its associated right-of-way and aggregate areas are not anticipated). An exception to this is that temporary features (for example, laydown areas, construction camps, some access roads) will be decommissioned and reclaimed or left to revegetate naturally are anticipated to provide functional marten habitat after 70 years or more, once mature, structurally complex forests have established.

During operations, the new linear feature as well as clearing associated with maintenance will result in a loss of habitat for American martens. During operations, habitat will be altered along the road right-of-way regularly during clearing conducted for ongoing maintenance.

Distribution

Although habitat will be initially removed during construction, the effects on American marten distribution from habitat loss and alteration will continue indefinitely through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

A total of 60 metres of the 100 metre wide right-of-way will be permanently disturbed during operations. As discussed above under Habitat Availability, reclamation of temporary features is expected to provide functional marten habitat after 70 years or more. This may reduce the connectivity of marten habitat and cause habitat fragmentation over the long term. Connectivity of marten habitat is currently limited only by natural features in the effects assessment Local Study Area. Anthropogenic linear features may impede marten movement in some areas; however, marten are strong dispersers and may continue to cross the road right-of-way even during operations.

Survival and Reproduction

The effects on American marten survival and reproduction from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated). However, American martens are not limited

by habitat availability in the wildlife effects assessment Regional Study Area and the small amount of vegetation removed for maintenance is unlikely to have a measurable effect on marten survival or reproduction beyond the effects assessment Construction Disturbance Area during operations.

Sensory Disturbance

Habitat Availability

Operation of the Community Access Road after construction as well as maintenance and inspection activities may also result in sensory disturbance. This effect has also been assessed as probable, though the magnitude of the effect is likely to be lower than that of the sensory disturbance during construction.

Survival and Reproduction

Sensory disturbance will be highest during construction but may continue after construction while the road is in use (medium to long term).

Increase in Predator Access

Distribution

Effects of the Project on the movement of other wildlife species (such as, wolves, Canada lynx, coyotes), may affect the distribution of American marten in the study area during operations. If predators or competitive species use either the Community Access Road or associated infrastructure as a movement corridor, American martens may avoid the area.

Survival and Reproduction

Some species that may prey on or compete with American martens can benefit from anthropogenic linear features such as roads, particularly during times when traffic is light. Linear features facilitate predator movement into areas that were previously less accessible (Brody and Pelton, 1989; Jalkotzy et al., 1997; Stuart-Smith et al., 1997; Rettie et al., 1998; James and Stuart-Smith, 2000; Tigner et al., 2014; Dickie et al., 2017, 2020). Coyotes, Canada lynx, and grey wolves may travel along the corridor during operations and may interact competitively with or prey upon American marten. This effect is more difficult to mitigate than that of the construction phase and will be permanent.

Incidental Take

Survival and Reproduction

Incidental take of denning American marten from direct habitat loss would be restricted to the effects assessment Construction Disturbance Area, but potential effects from disturbance to a den could occur at the local scale. This effect is considered to be infrequent because mitigation is expected to be effective.

Collisions with Vehicles and Equipment

Survival and Reproduction

During Operations, traffic volumes are expected to be greatest on the north-south section of the Community Access Road compared to the east-west section that connects to the Marten Falls First Nation. Traffic volumes are expected to vary temporally and spatially, with a greater volume occurring in the south compared to northernmost portions of the Community Access Road where human density is lower. As a result, most of the marten-vehicle collisions that occur during operations are likely to be attributed to collisions with public and industry vehicles that are not associated with the Project.

Long-term risks to American marten from collisions with vehicles and equipment are greater during operations when the Community Access Road is in use by the public. During operations, the speed limits will be higher and likely more difficult to enforce. The mortality risk from vehicle collision is permanent for as long as the road is in use.

Increase in Public Access

Survival and Reproduction

During operations, an increase in trapping pressure on American marten may correspond with an increase in public access along the corridor, both in the Community Access Road and temporary access roads. There are ten traplines that overlap the Local Study Area.

The potential increase in trapping and the corresponding increase in American marten mortality within the wildlife effects assessment Regional Study Area resulting from the increase in public access is not possible to predict because fur market prices and other unpredictable variables influence efforts expended on trapping.

9.4.3.4.13.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

Mitigation measures will be implemented to avoid, minimize, and restore the effects from the Project on American marten habitat availability, distribution, and survival and reproduction in the wildlife effects assessment Local Study Area and Regional Study Area.

A cleared right-of-way width of 60 metres will be maintained during operation of the road. Buffer zones of 30 metres will be maintained around waterbodies, clearing of riparian vegetation will be limited to the extent practicable and to the requirement of the access road and alignment clearing width only. Any American marten dens observed will be marked as sensitive sites and the location buffered appropriately to prevent disturbance as furbearer den sites are protected under the *Fish and Wildlife Conservation Act* 1997 (Government of Ontario, 1997).

An Environmental Protection Plan and a Cleanup and Reclamation Plan will be developed and implemented. Where necessary, seedling planting will occur to improve reclamation success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified. Reclamation plans will be confirmed through engagement with Indigenous communities, the Ministry of Natural Resources, and local foresters. Effectiveness of reclamation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities. If required, adaptive management will be employed to modify or enhance any reclamation efforts.

The effectiveness of mitigation measures will be evaluated during construction, Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Sensory Disturbance

Speed limits will be posted and enforced to reduce vehicle speeds and associated noise and dust emission levels.

The effectiveness of mitigation measures will be evaluated during construction, Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Increase in Predator Access

To minimize ongoing attraction of predators to the Project area, road kill will be cleaned up following best management practices outlined by Ontario's Ministry of Transportation and wildlife access to waste will be restricted. The ongoing use of inactive areas by predators will be minimized through physical control measures such as rollback, removal of creek crossings, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access.

The effectiveness of mitigation measures will be evaluated during operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Incidental Take

Mitigation measures described above will be applied during operations as required.

Collisions with Vehicles and Equipment

During operations, traffic will be restricted to approved right-of-way, workspace, and access roads or trails. Pits and quarries and other infrastructure required for maintenance activities will be gated to limit public access. A reporting protocol and system to report incidental wildlife observations and wildlife-vehicle collisions during construction and operations will be developed. Appropriate speed limits, wildlife crossing, and wildlife warning signage will be posted. Speed limits will be implemented and enforced.

These mitigation measures are expected to minimize the potential effects on American marten survival and reproduction. The effectiveness of mitigation measures will be evaluated during construction and post-construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Increase in Public Access

During operations, the Community Access Road will be accessible to the public but access roads for aggregate areas and other infrastructure required for maintenance activities will be gated to limit public access. Employees will be prohibited from hunting or carrying firearms while working on the Project maintenance.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.3.4.13.3 Predicted Residual Effects

Habitat Loss and Alteration

A permanent loss of 3,627 hectares of the available American marten habitat present in the effects assessment Local and Regional Study Area will occur within the Construction Disturbance Area. Temporary loss of additional habitat may occur during operations if clearing is required for maintenance activities. Marten habitat is not considered limiting within the effects assessment Local and Regional Study Area. There are residual effects predicted after implementation of the mitigation measures.

The effects of habitat loss and alteration on American marten are predicted to be certain, continuous, and irreversible. The direct effect of habitat loss will be confined to the Construction Disturbance Area. The effects of habitat loss and alteration will result in the fragmentation of contiguous habitat. The effects of fragmentation of habitat are predicted to occur at the scale of the Local Study Area.

After mitigation, the effects from habitat loss and alteration on the ability of the American marten population in the effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be **negative** and **low** in magnitude.

Sensory Disturbance

Sensory disturbance will be lower during operations but will be permanent during the operation of the Community Access Road. Mitigation should reduce the effect during maintenance activities, but not during operation. American martens in the effects assessment Local Study Area may experience some habitat fragmentation due to reduced crossings of the road.

Sensory disturbance will affect American martens with home ranges near the Community Access Road, a relatively small percentage of the martens expected to be present within the effects assessment Local and Regional Study Area. These animals are anticipated to modify their behaviours and habitat use.

The effects of sensory disturbance on American marten are predicted to be probable, continuous, irreversible, and confined to the wildlife effects assessment Local Study Area. Effects from habitat sensory disturbance on the ability of the American marten populations in the wildlife effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be **negative** and **low** in magnitude.

Increase in Predator Access

Mitigation, particularly of temporary access roads, will reduce but not eliminate the potential for the Project to increase interactions between American martens and predatory wildlife. The permanent road will provide a corridor that may be used by American marten predators, such as wolves, coyotes, and lynx to occupy new areas. As mesopredators, coyotes may have a measurable effect on the availability of food for mustelids. Both wolves and coyotes may alter the distribution of prey resources around the effects assessment Construction Disturbance Area. Changes to the movement of wolves and coyotes are expected to decline with distance from the Community Access Road, with the highest level of effect immediately surrounding the Construction Disturbance Area. There are residual effects predicted after implementation of the mitigation measures.

Effects on American marten survival and reproduction from increased predator access are predicted to be possible, continuous, permanent (permanent access roads) or long-term (decommissioned and revegetated access roads) and will be confined to the wildlife effects assessment Local Study Area. Effects from increased predator access on the ability of the American marten population to remain self-sustaining and ecologically functional are anticipated to be **negative** and **negligible** in magnitude.

Incidental Take

the Project because American marten are unlikely to attempt to den within the regularly maintained road right-of-way.

Effects from incidental take are predicted to be possible, medium-term and irreversible, infrequent, and confined to the effects assessment Construction Disturbance Area. Effects from incidental take on the ability of American marten in the effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and **low** in magnitude.

Collisions with Vehicles and Equipment

Collisions with vehicles and equipment may affect the survival of some American marten during operations. Only a very small proportion of the American marten population within the Regional Study Area is likely to be located near the effects assessment Construction Disturbance Area, and collisions with vehicles and equipment are likely to affect only a small number of these animals. There are residual effects predicted after implementation of the mitigation measures.

Effects are predicted to be possible, irreversible, continuous, and confined to the Construction Disturbance Area. Effects from collisions with vehicles and equipment on

the ability of the American marten populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative but **negligible** in magnitude.

Increase in Public Access

During operations, access to marten habitat near the Community Access Road will be permanently increased. An increase in trapping pressure may accompany this. Temporary access roads, even if they are blocked to road vehicles, may increase human accessibility on foot or by an all-terrain vehicle. A permanent increase in trapping pressure near the Community Access Road corridor is possible, with potential effects on American marten survival. Any increase in trapping mortality would decrease with distance from the Community Access Road and likely be highest for those animals whose home ranges are nearest the road. There are residual effects predicted after implementation of the mitigation measures.

The potential increase in trapping and the corresponding increase in American marten harvest within the wildlife effects assessment Regional Study Area resulting from the increase in public access is not possible to predict because fur market prices influence efforts expended on trapping.

After mitigation, effects from Increase in Public Access on the ability of the American marten population in the wildlife effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be negative but **low** in magnitude.

9.4.3.4.14 Changes to Furbearers (Beaver)

9.4.3.4.14.1 Potential Effects

Habitat Loss and Alteration

Habitat Availability

Although habitat will be initially removed during construction, the effects on beaver habitat availability from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

During operations, clearing of the right-of-way may remove vegetation that is a component of beaver foraging habitat. Intermittent changes to wetland habitat may occur during culvert maintenance and replacement, as well as bridge maintenance. Although, beaver guards will be installed to prevent beavers from damming culverts, beaver dams may need to be removed as part of culvert maintenance if beaver guards

are unsuccessful, and associated removals will temporarily disturb beaver habitat. Ministry of Transportation's Guide for Fisheries – Best Management Practices (2025) will be followed when beaver dams are removed from within a waterbody supporting fish and fish habitat.

Distribution

Although habitat will be initially removed during construction, the effects on beaver distribution from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Beavers are also likely to use culverts to construct dams (Tremblay et al., 2017). Dams within culverts may need to be removed to prevent flooding from damaging the road, if beaver guards are unsuccessful at preventing beavers from attempting to dam surface water flow at culverts. The associated removals may cause a temporary loss of habitat. This has been also noted as a concern by Indigenous communities who provided feedback/input on the Project in the form of Indigenous Knowledge (Dillon, 2024b; Marten Falls First Nation, 2023a).

The maintenance of the Community Access Road corridor to keep it clear of trees and shrubs which provide forage for beavers and the possible removal of beaver dams around the road may affect beaver habitat selection and distribution within the effect assessments Regional Study Area. The effects assessment Construction Disturbance Area is small compared to the size of beavers' home ranges on the local scale, and a measurable effect on beaver distribution is not expected from the Project.

Survival and Reproduction

Although habitat will be initially removed during construction, the effects on beaver survival and reproduction from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated). However, beavers are not limited by habitat availability in the wildlife effects assessment Regional Study Area and the small amount of vegetation removed for maintenance is unlikely to have a measurable effect on beaver survival or reproduction during operations.

Sensory Disturbance

Habitat Availability

Effects from sensory disturbances will be present but different during operations compared to during construction. During construction, activities will be primarily

confined to daylight hours and will be of relatively short duration (in other words, confined to the start and end of construction of each road segment).

Conversely, during operations, sensory disturbance will occur throughout the day over the life of the Project and along the full length of the road. Beavers' low sensitivity to sensory disturbance makes it unlikely that there will be a measurable effect on habitat availability because of sensory disturbance from the Project.

Survival and Reproduction

Sensory disturbances will likely be present but different during operations. Beavers' low sensitivity to sensory disturbance makes it unlikely that there will be a measurable

Increase in Predator Access

Distribution

Effects of the Project on the movement of beaver predators (in other words, wolves, lynx, coyotes), may affect the distribution of beavers in the study area during operations. Beavers avoid using foraging trails when predator scents are present (Severud et al., 2011), potentially affecting their distribution and habitat use.

Survival and Reproduction

Some species that may prey on beavers can benefit from anthropogenic linear features such as roads, particularly during times when traffic is light. Linear features facilitate predator movement into areas that were previously less accessible (Brody and Pelton, 1989; Jalkotzy et al., 1997; Stuart-Smith et al., 1997; Rettie et al., 1998; James and Stuart-Smith, 2000; Tigner et al., 2014; Dickie et al., 2017, 2020). Coyotes, grey wolves, and lynx may travel along the corridor during operations and may increase predation pressure on beavers in the wildlife effects assessment Local Study Area. This effect is more difficult to mitigate than that of the construction phase and will be permanent. However, little to no evidence has been found linking effects to beaver populations to increases in predation risk or industrial activities (in other words, roads, seismic lines) in northeast British Columbia (Mumma et al., 2018). In fact, studies have inferred that predators, and therefore predation risk, are incapable of limiting beaver population growth despite high levels of predation (Theberge and Theberge, 2004; Sidorovich et al., 2017).

Incidental Take

During operations, incidental take of beavers is possible if beaver dams or lodges need to be removed during maintenance of the road. Ministry of Transportation's Guide for

Fisheries – Best Management Practices (2025) will be followed when beaver dams are removed from within a waterbody supporting fish and fish habitat.

Collisions with Vehicles and Equipment

Survival and Reproduction

During Operations, traffic volumes are expected to be greatest on the north-south section of the Community Access Road compared to the east-west section that connects to the Marten Falls First Nation. Traffic volumes are expected to vary temporally and spatially, with a greater volume occurring in the south compared to northernmost portions of the Community Access Road where human density is lower. As a result, most of the beaver-vehicle collisions that may occur during operations are likely to be attributed to collisions with public and industry vehicles that are not associated with the Project.

Long-term risks to beaver from collisions and equipment are greater during operations when the Community Access Road will be used by the public. During operations, the speed limits will be higher and likely more difficult to enforce. The mortality risk from vehicle collisions is permanent for as long as the road is in use.

Increase in Public Access

Survival and Reproduction

Beavers may be adversely affected by improved public access during operations because this may lead to increased trapping pressures.

Beavers are important furbearers that may be trapped. Increased trapping mortality may correspond to an increase in access to the lands along the corridor. This effect may be particularly strong in areas adjacent to good beaver habitat, and around access roads and other construction and maintenance infrastructure. There are ten traplines that overlap the Local Study Area.

The potential increase in trapping and the corresponding increase in beaver mortality within the wildlife effects assessment Regional Study Area resulting from the increase in public access is not possible to predict because fur market prices and other unpredictable variables influence efforts expended on trapping.

9.4.3.4.14.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

Mitigation measures will be implemented to avoid, minimize, and restore the effects from habitat loss and alteration on beaver habitat availability, distribution, and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

A cleared width of less that 100 metres will be maintained unless otherwise required for operations. Vegetation clearing activities will be limited to the extent necessary for construction. All temporary construction infrastructure will be reclaimed as soon as possible following construction. Buffer zones of 30 metres will be maintained around waterbodies, clearing of riparian vegetation will be limited to the extent practicable and to the requirement of the access road and alignment clearing width only. Beaver lodges will be marked as sensitive sites and protected. A figure illustrating that location where beaver lodges were observed during existing conditions field surveys will be included in the Environmental Protection Plan. The Environmental Protection Plan will outline appropriate setbacks and procedures to be followed when beaver lodges are encountered during construction.

Temporary Project infrastructure used during construction only will be reclaimed as soon as possible following construction. An Environmental Protection Plan and a Cleanup and Reclamation Plan will be developed and implemented. Where necessary, seedling planting will occur to improve reclamation success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified. Reclamation plans will be confirmed through engagement with Indigenous communities, the Ministry of Natural Resources. Effectiveness of reclamation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities. If required, adaptive management will be employed to modify or enhance any reclamation efforts.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Sensory Disturbance

Speed limits will be posted and enforced to reduce vehicle speeds and associated noise and dust emission levels.

These mitigation measures are expected to minimize the potential effects on beaver habitat. The effectiveness of mitigation measures will be evaluated during construction and postconstruction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Increase in Predator Access

To minimize ongoing attraction of predators to the Project area, roadkill will be cleaned up following best management practices outlined by Ontario's Ministry of Transportation and wildlife access to waste will be restricted. The ongoing use of inactive areas by predators will be minimized through physical control measures such as rollback, removal of creek crossings, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access.

Incidental Take

Mitigation measures described in construction will be applied during operations as required.

Collisions with Vehicles and Equipment

During operations, traffic will be restricted to approved right-of-way, workspace, and access roads or trails. Pits and quarries and other infrastructure required for maintenance activities will be gated to limit public access. A reporting protocol and system to report incidental wildlife observations and wildlife-vehicle collisions during construction and operations will be developed. Appropriate speed limits, wildlife crossing, and wildlife warning signage will be posted. Speed limits will be implemented and enforced.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Increase in Public Access

During operations, the Community Access Road will be accessible to the public but access roads for aggregate areas and other infrastructure required for maintenance activities will be gated to limit public access. Employees will be prohibited from hunting or carrying firearms while working on Project maintenance.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.3.4.14.3 Predicted Residual Effects

Habitat Loss and Alteration

The permanent loss of habitat represents less than 1.53 percent of the available moderate to high-quality beaver habitat within the wildlife effects assessment Local Study Area, which will have a small effect on habitat availability and is unlikely to have more than a slight effect on beaver populations or distribution in the effects assessment Local Study Area. There are residual effects predicted after implementation of the mitigation measures.

Effects are predicted to be certain, irreversible, and continuous. The direct effect of habitat loss will be confined to the Construction Disturbance Area. The effects of habitat loss and alteration will result in the fragmentation of contiguous habitat. The effects of fragmentation of habitat are predicted to occur at the scale of the Local Study Area.

After mitigation, the effects from habitat loss on the ability of the beaver populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative but **negligible** in magnitude.

Sensory Disturbance

Suitable beaver habitat may be indirectly removed or degraded due to sensory disturbance form the Project. However, beavers are known to have low sensitivity to sensory disturbances. While sound and light cannot be completely mitigated during a construction project, only a small proportion of the population of beavers within the effects assessment Regional Study Area are located near the effects assessment Construction Disturbance Area. The implementation of mitigation measures is expected to limit negative effects from sensory disturbance from the Project. However, there are predicted net residual effects on beaver.

Effects are predicted to be possible, continuous, medium-term and reversible during construction, permanent and irreversible during operations, and confined to the wildlife effects assessment Local Study Area. After mitigation, the effects from sensory disturbance on the ability of beaver populations in the wildlife effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are expected to be negative but **negligible** in magnitude.

Increase in Predator Access

Mitigation, particularly of temporary access roads, will reduce the potential for the Project to cause interactions between beavers and other wildlife. The permanent road will provide a corridor that may be used by wolves and coyotes to expand their

presence in areas where they would have access to beavers as a prey resource. Both wolves and coyotes may alter the distribution of prey resources around the effects assessment Construction Disturbance Area. Changes to the movement of wolves and coyotes are expected to decline with distance from the Community Access Road, with the highest level of effect immediately surrounding the Construction Disturbance Area. There are residual effects predicted after implementation of the mitigation measures.

Effects are predicted to be irreversible, continuous, and confined to the wildlife effects assessment Local Study Area. After mitigation, the effects from increased predator access on the ability of beaver populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are expected to be negative but **negligible** in magnitude.

Incidental Take

During Operations, incidental take of beavers is possible if beaver dams or lodges need to be removed to maintain culverts. With mitigation, incidental take of beavers can be minimized or eliminated.

Effects of incidental take on beavers are predicted to be possible, permanent and irreversible during operations, infrequent, and confined to the Construction Disturbance Area. After mitigation, the effects from incidental take on the ability of beaver populations in the wildlife effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are expected to be negative but **negligible** in magnitude.

Collisions with Vehicles and Equipment

Collisions with vehicles and equipment may affect the survival of some beavers during operations. Only a very small proportion of the beaver population within the Regional Study Area is likely to be located near the effects assessment Construction Disturbance Area, and collisions with vehicles and equipment are likely to affect only a small number of these beavers. There are residual effects predicted after implementation of the mitigation measures.

Effects are predicted to be possible, irreversible, continuous, and confined to the Construction Disturbance Area. After mitigation, the effects from collisions with vehicles and equipment on the ability of beaver populations in the wildlife effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are expected to be negative but **negligible** in magnitude.

Increase in Public Access

During operations, access to beaver habitat near the Community Access Road will be permanently increased. An increase in trapping pressure may accompany this. Temporary access roads, even if they are blocked to road vehicles, may increase human accessibility on foot or by an all-terrain vehicle. A permanent increase in trapping pressure near the Community Access Road corridor is possible, with potential effects on beaver survival. Any increase in trapping mortality would decrease with distance from the Community Access Road and likely be highest for those animals whose home ranges are nearest the road. There are residual effects predicted after implementation of the mitigation measures.

After mitigation, the effects from increased public access on the ability of beaver populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are expected to be negative but **low** in magnitude.

9.4.3.4.15 Changes to Reptiles and Amphibians

9.4.3.4.15.1 Potential Effects

Habitat Loss and Alteration

Habitat Availability

Although habitat will be initially removed during construction, the effects on reptile and amphibian habitat availability from habitat loss will continue through Operations of the Project (such as, closure and reclamation of the road is not anticipated).

Parts of the effects assessment Construction Disturbance Area outside of the Community Access Road 60 metre right-of-way and within other areas of temporary construction disturbance may become reptile and amphibian habitat during operations. Maintenance activities with a high likelihood of disturbing reptile and amphibian habitat include reclearing along the Community Access Road 60 metre right-of-way, culvert maintenance and replacement, repairing damaged road surface, and grading.

Distribution

Although habitat will be initially removed during construction, the effects on reptile and amphibian distribution from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

During operations, habitat along the corridor will remain cleared. Habitat fragmentation will have the same effect as during construction, though the permanent fragmentation may have additional effects.

Survival and Reproduction

Although habitat will be initially removed during construction, the effects on reptile and amphibian survival and reproduction from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Sensory Disturbance

Habitat Availability

Intermittent sensory disturbances may temporarily alter the amount of available habitat within the corridor during operations, particularly when maintenance activities are underway that involve significant sound production or use of nighttime lighting. These disturbances are likely to be limited to the immediate vicinity of maintenance operations and are unlikely to further reduce available habitat beyond construction activities.

Survival and Reproduction

Sensory disturbances will likely be present but different and less impactful during operations. It unlikely that there will be a measurable effect on reptile and amphibian survival and reproduction because of sensory disturbance from the Project during operations.

Incidental Take

Survival and Reproduction

There is also a potential effect on reptile and amphibian survival and reproduction during operations. Incidental take during maintenance activities is possible, especially during culvert maintenance and replacement where changes in standing water depths can cause incidental take of eggs and tadpoles. Other maintenance activities such as clearing vegetation from the corridor and grading also pose a risk of incidental take to reptiles and amphibians.

Collisions with Vehicles and Equipment

Effects on the survival and reproduction of reptiles and amphibians will continue to be likely during operations. Road operation may have the greatest magnitude of effect as public vehicles travelling along the Community Access Road are likely to be travelling at higher speeds than vehicles involved in construction or maintenance activities.

During Operations, traffic volumes are expected to be greatest on the north-south section of the Community Access Road compared to the east-west section that

connects to the Marten Falls First Nation. Specifically, the predicted average annual daily traffic volumes are 700 vehicles on the north-south section and 100 vehicles on the east-west section (Appendix W). Heavy trucks will make up over half (64 percent) of the traffic on the north-south section while the traffic on the east-west section will consists of 3 percent heavy trucks and the remaining as light-duty vehicles and medium-size trucks. Traffic volumes are expected to vary temporally and spatially, with a greater volume occurring in the south compared to northernmost portions of the Community Access Road where human density is lower. As a result, most of the reptile and amphibian-vehicle collisions that occur during operations are likely to be attributed to collisions with public and industry vehicles that are not associated with the Project.

9.4.3.4.15.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

The Project footprint was designed to avoid removal of amphibian breeding habitat as much as practicable, wetland habitat loss will be offset as part of a future offset plan. Over the long term, measures undertaken as part of the Preliminary Biodiversity Offset Plan (**Appendix AB**) would be implemented to achieve a net increase in functional amphibian breeding habitat.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Sensory Disturbance

Speed limits will be posted and enforced to reduce vehicle speeds and associated noise and dust emission levels.

Incidental Take

Mitigation measures described above will be applied during operations as required.

Collisions with Vehicles and Equipment

During operations, traffic will be restricted to approved right-of-way, workspace, and access roads or trails. Pits and quarries and other infrastructure required for maintenance activities will be gated to limit public access. A reporting protocol and system to report incidental wildlife observations and wildlife-vehicle collisions during construction and operations will be developed. Speed limits will be implemented and enforced.

Additional mitigation during operations will include signage in areas where reptiles and amphibians are regularly observed.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.3.4.15.3 Predicted Residual Effects

Habitat Loss and Alteration

A permanent loss of 2,095 hectares of suitable amphibian breeding habitat is expected, representing about 0.6 percent of the total suitable habitat within the effects assessment Regional Study Area. An effect on reptiles of similar extent is expected. The implementation of mitigation and enhancement measures is expected to limit negative effects. However, there are residual effects predicted after implementation of the mitigation measures.

The effect of habitat loss and alteration is considered negative, irreversible, continuous, and certain to occur. The direct effect of habitat loss will be confined to the Construction Disturbance Area. The effects of habitat loss and alteration will result in the fragmentation of contiguous habitat. The effects of fragmentation of habitat are predicted to occur at the scale of the Local Study Area.

After mitigation, the effects from habitat loss and alteration on the ability of reptile and amphibian populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **low** in magnitude.

Sensory Disturbance

Sound, vibration, and light from construction areas cannot be completely mitigated, and some level of sensory disturbance will still be present during construction. Most reptiles and amphibians are not considered to have high sensitivity to sensory disturbances, and the Construction Disturbance Area covers a relatively small percentage of the Local Study Area. However, sensory disturbance could result in decreased mating success for anurans if calling is reduced or degraded by noise disturbance.

There is a predicted residual effect after the implementation of mitigation measures described previously. Reduced reproductive capacity is possible among affected reptiles and amphibians with breeding habitat within the effects assessment wildlife Local Study Area.

The effect is considered negative, local to the wildlife effects assessment Local Study Area, medium-term and reversible during construction, permanent and irreversible

during operations, continuous, and probable to occur. After mitigation, the effects from sensory disturbance during construction of the Project on the ability of reptile and amphibian populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

Incidental Take

Mitigation measures will reduce, but likely not eliminate the risk of incidental take of reptiles and amphibians during operations. Effects on mortality will be localized to work areas and transportation corridors and will likely include only a small number of animals.

During operations, incidental take may be largely caused by maintenance operations and chemical applications on the Community Access Road surface.

There is a predicted residual effect after implementation of the mitigation measures.

The effect is considered negative, confined to the Construction Disturbance Area, medium term, infrequent, during construction, permanent and irreversible during operations, and probable to occur. After the implementation of mitigation, the effects from incidental take on the ability of reptile and amphibian populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **low** in magnitude.

Collisions with Vehicles and Equipment

With mitigation, reptile and amphibian mortalities from collisions with vehicles and equipment during construction could be minimized. Reptile and amphibian mortalities resulting from vehicle collisions during operations are expected to occur. There is a predicted residual effect after the implementation of mitigation measures described previously.

During the next phase of the Project, in the Detail Design stage the incorporation of sub-surface eco-passages and exclusion fencing at strategic locations such as culverts, are predicted to partially mitigate the effect of collisions with vehicles and equipment during operations.

Implementation of mitigation measures are expected to be effective at minimizing the likelihood of reptile and amphibian collisions with Project vehicles and equipment during construction but are not expected to be as effective during operations because they will be less enforceable amongst public users of the Community Access Road. Because of this, effects are predicted to be probable during construction and certain during operations, irreversible, continuous, and confined to the Construction Disturbance Area. After mitigation, the effects from collisions with vehicles and equipment on the ability of

the reptile and amphibian populations in the wildlife effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative but **low** in magnitude.

9.4.3.4.16 Changes to Pollinating Insects

9.4.3.4.16.1 Potential Effects

Habitat Loss and Alteration

Habitat Availability

Although habitat will be initially removed during construction, the effects on pollinating insect habitat availability from habitat loss will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated). During operations, permanent clearing of the Community Access Road and associated maintenance infrastructure will maintain the loss of nesting habitat for bees and overwintering habitat for all insect species.

Distribution

Although habitat will be initially removed during construction, the effects on pollinating insect distribution from habitat loss will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

During operations, some edge habitat will be established that may host shrubs that benefit bumble bees and lady beetles, but plant habitats will be lost within the Community Access Road and permanent maintenance infrastructure. The net effect of this change in habitat is unclear, but as a precautionary approach, it will be considered a net loss of habitat.

Survival and Reproduction

Pollinating insects are not limited by habitat availability in the wildlife effects assessment Local and Regional Study Areas and the small amount of vegetation removed for maintenance is unlikely to have a measurable effect on the survival or reproduction of pollinating insects during operations.

Sensory Disturbance

Habitat Availability and Survival and Reproduction

Sensory disturbance during construction and operations could result in the indirect loss or degradation of suitable pollinator habitat if individuals avoid areas with sensory

disturbance. The effects of noise and artificial light on pollinating insects are unknown. There is inconclusive evidence of whether bumble bees and lady beetles are considered sensitive to anthropogenic disturbances such as noise and light; however, current scientific understanding suggests that further research on the subject is required.

Incidental Take

During operations, incidental take of pollinating insects may occur during clearing along the edges of the Community Access Road corridor. Vegetation that provides habitat for insects as well as ground nests or overwintering spots may be removed by maintenance activities. However, this is unlikely to have a measurable effect on insect populations in the Regional Study Area.

Collisions with Vehicles and Equipment

During operations, public vehicle use of the Community Access Road poses the highest risk of incidental mortality to insects. Maintenance vehicles may also collide with insects during operations.

During Operations, traffic volumes are expected to be greatest on the north-south section of the Community Access Road compared to the east-west section that connects to the Marten Falls First Nation. Traffic volumes are expected to vary temporally and spatially, with a greater volume occurring in the south compared to northernmost portions of the Community Access Road where human density is lower. As a result, most of the pollinating insect-vehicle collisions that may occur during operations are likely to be attributed to collisions with public and industry vehicles that are not associated with the Project.

9.4.3.4.16.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

Mitigation measures will be implemented to avoid, minimize, and restore the effects from the Project on pollinating insect habitat availability, distribution, and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

The Project footprint will be limited to the extent feasible. Existing access roads will be used where possible. Decommission and rehabilitate temporary access roads, staging areas, camps, and debris and / or timber stockpiles following construction.

An Environmental Protection Plan and a Cleanup and Reclamation Plan will be developed and implemented. Where necessary, seedling planting will occur to improve

reclamation success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified. Reclamation plans will be confirmed through engagement with Indigenous communities, the Ministry of Natural Resources and local foresters. Effectiveness of reclamation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities. If required, adaptive management will be employed to modify or enhance any reclamation efforts.

Buffer zones of 30 metres will be maintained around waterbodies, clearing of riparian vegetation will be limited to the extent practicable and to the requirement of the access road and alignment clearing width only.

If seeding is necessary for reclamation of temporary construction infrastructure, a native plant seed mix will be used. Roadside ditches / rights-of-way present a mitigation opportunity for native pollinators. Through establishment of appropriate plant communities and implementation of Integrated Vegetation Management, a suitable forage habitat can be maintained while still performing the safety / functionality of rights-of-way (Wojcik and Buchmann, 2012; United States Environmental Protection Agency, 2008).

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Sensory Disturbance

Mitigation measures will be implemented to avoid, minimize, and restore the effects of sensory disturbance on pollinating insect habitat availability, and survival and reproduction in the wildlife effects assessment Local Study Area and wildlife Regional Study Area.

Although bumble bees and lady beetles may not be considered to be sensitive to sensory disturbances, mitigations for sensory disturbance in other valued components may benefit these species.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Incidental Take

Mitigation measures described above will be applied during operations as required.

Collisions with Vehicles and Equipment

Operations traffic will be restricted to approved right-of-way, workspaces and access roads or trails. Speed limits will be implemented and enforced.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.3.4.16.3 Predicted Residual Effects

Habitat Loss and Alteration

The Project will result in the removal of 4,700 hectares of mostly undisturbed natural habitat, the majority of which is vegetated and provides suitable nesting, overwintering and foraging resources for pollinating insects. This loss of habitat represents a small portion of the available habitat within the wildlife effects assessment Regional Study Area. There is a predicted residual effect after the implementation of mitigation measures described previously.

The effect is considered negative, irreversible, continuous, and certain to occur. The direct effect of habitat loss will be confined to the Construction Disturbance Area. The effects of habitat loss and alteration will result in the fragmentation of contiguous habitat. The effects of fragmentation of habitat are predicted to occur at the scale of the Local Study Area.

After mitigation, the effects from habitat loss and alteration on the ability of pollinating insect populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

Sensory Disturbance

Bumble bees are tolerant to sensory disturbances such as sound and light. Lady beetles are not known to be sensitive to sensory disturbances. This effect is expected to have **no** effect on pollinating insects of concern during construction and operations. No residual effect of sensory disturbance on pollinating insects is predicted.

Incidental Take

Mitigation will reduce but not eliminate incidental take. The population of insects within the Construction Disturbance Area is expected to be a small fraction of the insects within the Local Study Area. There are residual effects predicted after implementation of the mitigation measures.

The effect is considered negative, local to the Construction Disturbance area, permanent and irreversible during operations, infrequent, and probable to occur. After mitigation, the effects from incidental take on the ability of pollinating insect populations in the wildlife effects assessment Regional Study Area to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

Collisions with Vehicles and Equipment

Insect mortality will occur from collisions with vehicles and equipment during both construction and operations. It is unlikely that a large percentage of the pollinating insects within the effects assessment Regional Study Area will use the Community Access Road and consequently be subject to this risk. There are residual effects predicted after implementation of the mitigation measures.

The effect is considered negative, confined to the Construction Disturbance area, irreversible, continuous, and probable to occur. After mitigation, the effects from collisions with vehicles and equipment on the ability of pollinating insect populations in the wildlife Regional Study Areas to remain self-sustaining and ecologically functional are predicted to be **negligible** in magnitude.

9.4.3.5 Summary of Residual Effects

Table 9.4-9 provides a summary of the potential effects for wildlife, mitigation measures, and residual effects. Detailed information is included in **Appendix K**.

Table 9.4-9: Summary of Residual Effects for Wildlife

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **All Wildlife Valued Components**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*. • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Introduction and spread of invasive plant species—Can affect plant community composition, which can affect wildlife habitat availability and distribution.	• A comprehensive list of mitigation measures to control weeds during construction is provided in the Vegetation Technical Support Document (**Appendix J**) and Peatlands Technical Support Document (**Appendix I**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources, will be followed during construction and operations.	• Residual changes from the introduction and spread of invasive plant species	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Significant: Not Significant • Uncertainty: Low • Direct / Indirect: Indirect

• **Furbearers (American marten)**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Collisions with vehicles and equipment—Collisions with Project vehicles during construction and operations may cause injury or mortality to individual animals.	• Speed limits will be posted and enforced to reduce vehicle speeds and associated collisions with wildlife. • Operations traffic will be restricted to approved right-of-way, workspace and access roads or trails. • Pits and quarries and other infrastructure required for maintenance activities will be gated to limit public access. • Implement an Environmental Protection Plan that includes the following measures to minimize collisions between wildlife and vehicles during Maintenance: provide driver training to Maintenance workers to understand the importance of reducing vehicle speeds, spread awareness of local wildlife, give wildlife the right-of-way, communicate the presence of wildlife along access roads and on site to other employees, and mandatory reporting of wildlife collisions. • Worker transportation to site will be coordinated to reduce traffic volumes. • Employees and owner / operators will be subject to restrictions while working including prohibition of personal snowmobiles, all-terrain vehicles and other motorized recreational vehicles; and speeding on roads. Confining vehicle traffic to approved right-of-way, workspace, and access roads. • A reporting protocol and system will be developed to report incidental wildlife observations and wildlife-vehicle collisions during Operations. • Blocking winter roads and temporary access routes and trails no longer required as Maintenance proceeds. • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources.	• Residual change to American marten from collisions with vehicles	• Context: • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration: Permanent • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Possible • Significant: Not Significant • Uncertainty: High • Direct / Indirect: Direct

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Furbearers (American marten)**	• Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Increase in public access—Could affect American marten survival and reproduction through increased trapping efforts.	• Access roads used for permanent maintenance activities will be blocked while not in use. • Employees will be prohibited from hunting or carrying firearms while working on the Project maintenance. • Implement an Environmental Protection Plan that includes the following measures to control, and / or restrict public use of access roads during construction and operations: speed limits, gates / manned gates, signage, reduced road standard, felling of timber across temporary access roads after reclaimed, removal of temporary watercourse crossings, reduce traffic by locating camps near construction sites. Posting of restricted access and speed signage will follow the Construction Specification for Temporary Traffic Control Devices (Ministry of Transportation, 2025). • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources. Temporary access roads and other temporary construction infrastructure will be reclaimed as quickly as possible following construction. As part of the reclamation of temporary access roads, access to these roads will be physically blocked to decrease public use.	• Residual changes to American marten from increase in public access	• Context: Ecological. • Direction: Negative • Magnitude: Low • Geographic Extent: Local • Duration: Permanent • Frequency: Continuous until Construction is over • Reversibility: Irreversible • Likelihood: Possible • Significant: Not Significant • Uncertainty: High • Direct / Indirect: Indirect

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Furbearers (American marten)**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Increase in public access—Could affect American marten survival and reproduction through increased trapping efforts.	• Access roads used for permanent maintenance activities will be blocked while not in use. • Employees will be prohibited from hunting or carrying firearms while working on the Project maintenance. • Implement an Environmental Protection Plan that includes the following measures to control, and / or restrict public use of access roads during Operations: speed limits, gates / manned gates, signage, reduced road standard, felling of timber across temporary access roads after reclaimed, removal of temporary watercourse crossings, reduce traffic by locating camps near construction sites. Posting of restricted access and speed signage will follow the Construction Specification for Temporary Traffic Control Devices (Ministry of Transportation, 2025). • During Operations, the Community Access Road will be accessible to the public but access roads for aggregate areas and other infrastructure required for maintenance activities will be gated to limit public access. • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources.	• Residual changes to American marten from increase in public access	• Context: Ecological. • Direction: Negative • Magnitude: Low • Geographic Extent: Local • Duration: Permanent • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Possible • Significant: Not Significant • Uncertainty: High • Direct / Indirect: Indirect

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Furbearers (beaver)**	• Temporary construction staging areas • Temporary access roads and trails • Temporary construction camps • Right-of-way clearing and grubbing • Pits and quarries • Temporary concrete batch plants • Drilling / blasting / aggregate production • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls)	• Construction	• Habitat loss and alteration—Habitat loss is the direct removal or alteration of soil and vegetation that may change habitat availability, use, and connectivity and influence beaver abundance and distribution.	• Limit the Project footprint to the extent feasible. • Use existing access roads where possible. • Any beaver lodge observed will be marked as sensitive and protected. • Maintain buffer zones of 30 metres around waterbodies, and limit clearing of riparian vegetation to the extent practicable and to the requirement of the access road and alignment clearing width only. • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources. • Temporary access roads and trails, construction camps, turnaround areas, waterbody crossings and temporary laydown areas will be reclaimed at the end of construction. • An Environmental Protection Plan and a Cleanup and Reclamation Plan will be developed and implemented. Where necessary, seedling planting will occur to improve reclamation success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified. Reclamation plans will be confirmed through engagement with Indigenous communities, the Ministry of Natural Resources and local foresters. Effectiveness of reclamation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities. If required, adaptive management will be employed to modify or enhance any reclamation efforts. • The loss and alteration of beaver habitat will be minimized to the extent possible and will be undertaken in compliance with the requirements of the *Fisheries Act* (1985).	• Residual changes to beaver from habitat loss and alteration	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area (direct habitat loss) / Local Study Area (habitat fragmentation) • Duration: Permanent • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Certain • Significant: Not Significant • Uncertainty: Low • Direct / Indirect: Direct

				snowmobiles, all-terrain vehicles and other motorized recreational vehicles; and speeding on roads. Confining vehicle traffic to approved right-of-way, workspace, and access roads. • A reporting protocol and system will be developed to report incidental wildlife observations and wildlife-vehicle collisions during Operations. • Sub-surface eco-passages and exclusion fencing will be established at culverts along the north-south segment of the Community Access Road. • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources.		
• **Pollinating Insects**	• Temporary construction staging areas • Temporary access roads and trails • Temporary construction camps • Right-of-way clearing and grubbing • Pits and quarries • Temporary concrete batch plants • Drilling / blasting / aggregate production • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls)	• Construction	• Habitat loss and alteration—The direct removal or alteration of soil and vegetation that may change habitat availability, use, and connectivity and influence pollinating insect abundance and distribution.	• Limit the Project footprint to the extent feasible. • Use existing access roads where possible. • Maintain buffer zones of 30 metres around waterbodies, and limit clearing of riparian vegetation to the extent practicable and to the requirement of the access road and alignment clearing width only. • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources. • Temporary access roads and trails, construction camps, turnaround areas, waterbody crossings and temporary laydown areas will be reclaimed at the end of construction.	• Residual changes to pollinating insects from habitat loss and alteration	• Context: Ecological • Direction: Negative • Magnitude: Negligible magnitude • Geographic Extent: Construction Disturbance Area (direct habitat loss) / Local Study Area (habitat fragmentation) • Duration: Permanent • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Certain • Significant: Not Significant • Uncertainty: Low • Direct / Indirect: Direct

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
				• An Environmental Protection Plan and a Cleanup and Reclamation Plan will be developed and implemented. Where necessary, seedling planting will occur to improve reclamation success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified. Reclamation plans will be confirmed through engagement with Indigenous communities, the Ministry of Natural Resources and local foresters. Effectiveness of reclamation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities. If required, adaptive management will be employed to modify or enhance any reclamation efforts.		
• **Pollinating Insects**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Habitat loss and alteration—The direct removal or alteration of soil and vegetation that may change habitat availability, use, and connectivity and influence pollinating insect abundance and distribution.	• Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources.	• No residual effects anticipated	• No residual effects anticipated
• **Pollinating Insects**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Pits and quarries • Drilling / blasting / aggregate production	• Construction	• Sensory disturbance—(for example, lights, smells, noise, human activity) can alter wildlife habitat availability, use, and connectivity (movement and behaviour), which can lead to changes in abundance and distribution and adversely affect survival and reproduction.	• Construction traffic will be restricted to designated areas. • During construction, access to the Community Access Road corridor will be restricted to construction personnel. • Noise-producing equipment will be fitted with noise-reducing components, where feasible, and these components will be maintained. • Unnecessary idling of vehicles and equipment will be limited on construction sites. • Wildlife awareness training will be provided for road construction workers to reduce vehicle speeds and associated noise and dust emission levels.	• No residual effects anticipated	• No residual effects anticipated

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
				• Industry best practices will be used for blasting activities, including scheduling when in the vicinity of sensitive wildlife sites. • Vegetation buffers will be retained around quarries to reduce noise, where feasible. • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources.		
• **Pollinating Insects**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Sensory disturbance—(for example, lights, smells, noise, human activity) can alter wildlife habitat availability, use, and connectivity (movement and behaviour), which can lead to changes in abundance and distribution and adversely affect survival and reproduction.	• Speed limits will be posted and enforced to reduce vehicle speeds and associated noise. • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, and Ontario Ministry of Natural Resources.	• No residual effects anticipated	• No residual effects anticipated

9.4.4 Birds

9.4.4.1 Project-Environment Interactions

As a component of the effects assessment, the Project activities were reviewed to find potential environmental interactions. These interactions were then assessed for potential effect (**Table 9.4-10**).

Table 9.4-10: Project-Environment Interactions - Birds

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production; • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Introduction and spread of invasive plant species—can affect plant community composition, which in turn can affect bird habitat availability and distribution.
• **Operations**	• Operate the Community Access Road; and • Maintain the Community Access Road.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Introduction and spread of invasive plant species—can affect plant community composition, which in turn can affect bird habitat availability and distribution.
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Emissions of criteria air contaminants—deposition of particulates in criteria air contaminant emissions (for example potential acid inputs) may change soil and vegetation quality and affect bird habitat availability and distribution.
• **Operations**	• Operate the Community Access Road; • Maintain the Community Access Road.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Emissions of criteria air contaminants—deposition of particulates in criteria air contaminant emissions (for example potential acid inputs) may change soil and vegetation quality and affect bird habitat availability and distribution.

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production; • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Fugitive dust emissions—deposition of dust particulates may change soil and vegetation quality and affect bird habitat availability and distribution.
• **Operations**	• Operate the Community Access Road; • Maintain the Community Access Road.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Fugitive dust emissions—deposition of dust particulates may change soil and vegetation quality and affect bird habitat availability and distribution.
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production; • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Erosion and sedimentation—can alter surface water, groundwater, soil, and vegetation quality and affect bird habitat availability and distribution.
• **Operations**	• Operate the Community Access Road • Maintain the Community Access Road	• All bird valued components	• Habitat Availability • Habitat Distribution	• Erosion and sedimentation—can alter surface water, groundwater, soil, and vegetation quality and affect bird habitat availability and distribution.
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production;	• All bird valued components	• Habitat Availability • Habitat Distribution	• Changes to surface water quantity—alteration of surface water drainage patterns, flows, and levels that can cause changes to soils and vegetation, which can affect bird habitat availability and distribution.

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
	• Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.			
• **Operations**	• Operate the Community Access Road; and • Maintain the Community Access Road.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Surface water quantity—alteration of surface water drainage patterns, flows, and levels that can cause changes to soils and vegetation, which can affect bird habitat availability and distribution.
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production; • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Surface water quality—changes in surface water quality from Project activities could adversely affect bird habitat availability and distribution.
• **Operations**	• Operate the Community Access Road; and • Maintain the Community Access Road.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Surface water quality—changes in surface water quality from Project activities could adversely affect bird habitat availability and distribution.
• **Construction**	• Mobilization of equipment and supplies. • Temporary construction staging areas. • Temporary access roads and trails. • Temporary construction camps. • Right-of-way clearing and grubbing. • Pits and quarries. • Temporary concrete batch plants. • Drilling / blasting / aggregate production. • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching). • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls). • Construction site restoration. • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Changes to groundwater —alteration of groundwater drainage and infiltration patterns, flows, and levels that can cause changes to soils and vegetation, which can affect bird habitat availability and distribution.

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Operations**	• Pits and quarries; • Operate the Community Access Road; and • Maintain the Community Access Road.	• All bird valued components	• Habitat Availability • Habitat Distribution	• Changes to groundwater—alteration of groundwater drainage and infiltration patterns, flows, and levels that can cause changes to soils and vegetation, which can affect bird habitat availability and distribution.
• **Construction**	• Temporary construction staging areas • Temporary access roads and trails • Temporary construction camps • Right-of-way clearing and grubbing • Pits and quarries • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Survival and Reproduction	• Incidental take—Vegetation removal and soil alterations during site preparation for construction and operations activities, and infrastructure (for example, camp buildings) removal during decommissioning may result in destruction of nests, eggs, and individuals of birds.
• **Operations**	• Maintain the Community Access Road	• All bird valued components	• Survival and Reproduction	• Incidental take—Vegetation removal and soil alterations during site preparation for construction and operations activities, and infrastructure (for example, camp buildings) removal during decommissioning may result in destruction of nests, eggs, and individuals of birds.
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production; • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the Aggregate Resources Ac; and. • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Survival and Reproduction	• Collision with vehicles and equipment—Collisions of birds with vehicles or heavy equipment may cause injury or mortality to individual birds.
• **Operations**	• Operate the Community Access Road; and • Maintain the Community Access Road.	• All bird valued components	• Survival and Reproduction	• Collision with vehicles and equipment—Collisions of birds with vehicles or heavy equipment may cause injury or mortality to individual birds.

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production; • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Survival and Reproduction	• Wildlife attractants—Attraction of wildlife to the Community Access Road can affect bird survival and reproduction through increased mortality risk and changes to predator-prey relationships.
• **Operations**	• Operate the Community Access Road; and • Maintain the Community Access Road	• All bird valued components	• Survival and Reproduction	• Wildlife attractants—Attraction of wildlife to the Community Access Road can affect bird survival and reproduction through increased mortality risk and changes to predator-prey relationships.
• **Construction**	• Pits and quarries; • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); and • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls).	• All bird valued components	• Survival and Reproduction	• Blasting and fly rock—May result in injury or mortality to birds.
• **Operations**	• Maintain the Community Access Road	• All bird valued components	• Survival and Reproduction	• Blasting and fly rock—May result in injury or mortality to birds.
• **Construction**	• Mobilization of equipment and supplies; • Temporary construction staging areas; • Temporary access roads and trails; • Temporary construction camps; • Right-of-way clearing and grubbing; • Pits and quarries; • Temporary concrete batch plants; • Drilling / blasting / aggregate production; • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching); • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls); • Construction site restoration; • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*; and • Decommissioning of temporary camps, roads / trails and staging areas.	• All bird valued components	• Survival and Reproduction	• Chemical or hazardous material stored on the Project site, or spills (for example, petroleum products, ammonium nitrate) can affect bird habitat availability and distribution.
• **Operations**	• Operate the Community Access Road; and • Maintain the Community Access Road.	• All bird valued components	• Survival and Reproduction	• Chemical or hazardous material stored on the Project site, or spills (for example, petroleum products, ammonium nitrate) can affect bird habitat availability and distribution.

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction

9.4.4.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following birds definitions apply to the effects assessment.

Ecological and Social Context

Ecological context for the bird valued components, context included species sensitivity, resilience, and adaptive capacity, current status and trends, and legislation and best management practices, incorporating Indigenous Knowledge where available. Consideration of ecological context includes timing, such as when the effect could occur during a critical life cycle of the valued component. Context also informs whether the residual effect would alter the ability of the valued component bird populations to be self-sustaining and ecologically effective (in other words, the determination of significance). Ecological context is discussed in a reasoned narrative with other characteristics such as magnitude, geographic extent, duration, reversibility, and probability of occurrence used to characterize residual effects and determine significance.

Magnitude

Integrating ecological context to understand the point at which a given magnitude is large enough to be critical for a valued component is directly linked to the self-sustaining and ecologically effective status of the population, and therefore directly linked to significance. For magnitude, environmental discipline-specific definitions are required and are provided in **Table 9.4-11** Magnitude of effects are project-related and exclude variations due to climate change.

Table 9.4-11: Bird Magnitude Definition

Magnitude Level	Definition	Rationale
• **Negligible**	• Limited to no variation predicted in the measurement indicators for bird valued components	• Changes to ecosystems or populations are minor and largely indiscernible; therefore, no effect on population resilience.
• **Low**	• A small variation predicted in the measurement indicators for bird valued components	• Minor incremental effects on ecosystems or populations are anticipated to be discernible but remain within the limits of ecosystem or population resilience.
• **Medium**	• A moderate variation predicted in the measurement indicators for bird valued components	• Incremental effects on ecosystems or populations are anticipated to be measurable but is inferred to remain within the limits of population resilience.
• **High**	• A large variation predicted in the measurement indicators for bird valued components	• Effects on ecosystems or populations are anticipated to be severe and likely to impair population resilience.

9.4.4.3 Residual Effects - Construction Phase

9.4.4.3.1 Changes to Birds Through the Introduction of Invasive Plant Species

9.4.4.3.1.1 Potential Effects

Habitat Availability and Distribution

Invasive plant species often establish in fragmented landscapes along edge habitats, such as cleared areas adjacent to roads (Lafortezza et al., 2010). Most non-native invasive plant species are introduced through various forms of human transport (Mack et al., 2000; Reichard and White, 2001). The regular movement of vehicles, equipment, and personnel associated with the Community Access Road could transport invasive plant seeds or plant parts into new areas in the effects assessment Construction Disturbance Area. Additionally, land clearing in the effects assessment Construction Disturbance Area will remove vegetation and disturb soils, increasing the potential for invasive plant species to establish and spread along the right-of-way and other areas of edge habitats in the effects assessment Construction Disturbance Area.

Invasive plant species thrive in areas with recently disturbed soils and a high ratio of edge habitat as this improves their ability to establish and spread (Honnay et al., 2002). As discussed in the Vegetation Technical Support Document (**Appendix J**) and Peatlands Technical Support Document (**Appendix I**) the introduction of invasive plant species into new areas can alter vegetation species diversity and the community plant structure through competition with native species, and by changing soil conditions (for example, nutrients, moisture) (Mack et al., 2000; Carlson and Shepherd, 2007; Truscott et al., 2008). These changes could have negative effects on bird habitat availability and distribution.

9.4.4.3.1.2 Mitigation and Enhancement Measures

A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control invasive plant species. Herbicides or pesticides will not be used at any stage of the Community Access Road construction. A comprehensive list of mitigation measures to control invasive plant species during construction of the Community Access Road is provided in the Vegetation Technical Support Document (**Appendix J**) and Peatlands Technical Support Document (**Appendix I**). Mitigation measures to limit the introduction and spread of invasive plants are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.1.3 Predicted Residual Effects

Invasive plant species may occasionally be introduced within the effects assessment Construction Disturbance Area during the construction and operations phase. Best management practices and mitigation measures for controlling the spread of invasive species that will be implemented during construction are well understood, and the methods have been demonstrated to be effective. However, introduction of invasive plant species could still occur during construction, even following mitigation. Additionally, introduction of invasive plant species may be higher during operations due to public use of the Community Access Road. As such, the Community Access Road is expected to have net residual effects on birds and their habitats, relative to existing conditions and this interaction was carried forward into the residual effects characterization.

After implementation of mitigation, effects from the introduction of invasive plants are predicted to be possible to occur, reversible in the short term (construction) to long term (operations phase), infrequent, and confined to the effects assessment Construction Disturbance Area. Effects from the introduction of invasive plants on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude.

9.4.4.3.2 Changes to Birds from Emissions of Criteria Air Contaminants

9.4.4.3.2.1 Potential Effects

Habitat Availability and Distribution

Construction of the Community Access Road are expected to generate air particulate emissions, including carbon monoxide, sulphur oxides (including sulphur dioxide), nitrogen oxides, and particulate matter. Construction activities are expected to produce air emissions from the use of construction vehicles, motorized equipment and machinery, power generators (to be used at temporary construction camps and temporary aggregate areas), the use of explosives (blasting), and the burning of non-hazardous waste materials (for example, food garbage at temporary construction camps).

The deposition of criteria air contaminant emissions can result in changes to soil and surface water quality, which has the potential to alter plant community structure, composition, and diversity by modifying the pH, nutrient content, and abundance and diversity of living organisms. Contamination of water, soil, and vegetation quality from deposition of Community Access Road air emissions has the potential to negatively

affect birds if it reduces the quality of suitable forage and habitat, which could ultimately affect the distribution of bird populations. This was also a concern that was also noted by Indigenous communities including Mushkegowuk Council, Kingfisher Lake First Nation, and Animbiigoo Zaagi'igan Anishinaabek (NextBridge Infrastructure, 2018; SNC Lavallin, 2020; Stantec, 2017b). The concern was noted through shared Indigenous Knowledge particularly relating to effects on birds as a result exposure / ingestion of contaminants due to emissions.

Air quality modelling was used to predict maximum ground-level concentrations of criteria air contaminant emissions during the construction and operations phases. The methods and results for air quality modelling are presented in detail in the Atmospheric Environment Technical Support Document (**Appendix S**). During construction, most air criteria contaminants were predicted to be below Canadian Ambient Air Quality Standards and / or Ontario Ambient Air Quality Criteria thresholds. However, threshold exceedances were noted for nitrogen dioxide and sulphur dioxide, carbon monoxide, acrolein, and benzo(a)pyrene emissions. Most threshold exceedances were limited to less than 760 metres from the emission source. The exceptions are nitrogen dioxide, sulphur dioxide, carbon monoxide emissions during quarry blasting. During quarry blasting, nitrogen dioxide and sulphur dioxide emissions thresholds may be exceeded by up to 12.3 kilometres, while carbon monoxide emissions may exceed the Ontario Ambient Air Quality Criteria threshold out to 1.5 kilometres.

It should be noted that the Air Quality modelling incorporated conservative assumptions (in other words, using worst-case scenarios) to make sure that effects were not underestimated.

9.4.4.3.2.2 Mitigation and Enhancement Measures

Potential mitigation measures outlined in the Ontario Ministry of Transportation Environmental Guide for Assessing and Mitigating the Air Quality Impacts and Greenhouse Gas Emissions for Provincial Transportation Projects (Ontario Ministry of Transportation, 2020) may be implemented, if feasible. A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during construction. Mitigation measures to limit emissions of criteria air contaminants are well understood and the methods have been demonstrated to be effective. A comprehensive list of mitigation measures that will be implemented to limit air particulate emissions during construction is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).

9.4.4.3.2.3 Predicted Residual Effects

As discussed in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I**), emissions of criteria air contaminants are anticipated to have negligible, possible effects on vegetation ecosystems, and, ultimately, bird habitat. As such, this interaction was determined to have no residual effects on bird habitat availability and distribution and is not carried forward in the assessment.

9.4.4.3.3 Changes to Birds from Fugitive Dust Emissions

9.4.4.3.3.1 Potential Effects

Habitat Availability and Distribution

Fugitive dust emissions were a concern that was highlighted by Indigenous communities including Marten Falls First Nation, Weenusk First Nation, and Aroland First Nation (Marten Falls First Nation, 2023, MNP LPP, 2024b; Shared Value Solutions, 2024). Fugitive dust emissions are expected to be produced during construction activities such as land clearing, blasting, and infrastructure implementation (Atmospheric Environment Technical Support Document; **Appendix S**). Accumulation of airborne dust produced from the Community Access Road may result in direct, localized changes to vegetation. For example, deposition of airborne dust onto vegetation can smother plant tissues, hinder gas exchange, and reduce photosynthesis by physically blocking sunlight (Farmer 1993). Consequently, the deposition of dust can and alter plant species composition, structure, and biomass. As a result, dust generated by Project Construction activities could adversely affect birds by degrading habitat quality and forage availability and distribution.

Air quality modelling was used to predict maximum ground-level concentrations of criteria air contaminant emissions during construction (Atmospheric Environment Technical Support Document; **Appendix S**). Threshold exceedances for the Community Access Road during construction are predicted for total suspended particulate, particulate matter less than 2.5 micrometres and particulate matter less than 10 micrometres emissions. Threshold exceedances for dust emissions are predicted to be reached at less than 300 metres from the emission source.

It should be noted that the Air Quality modelling incorporated conservative assumptions (in other words, using worst-case scenarios) to make sure that effects were not underestimated.

9.4.4.3.3.2 Mitigation and Enhancement Measures

Potential mitigation measures outlined in the Ontario Ministry of Transportation Environmental Guide for Assessing and Mitigating the Air Quality Impacts and Greenhouse Gas Emissions for Provincial Transportation Projects (Ontario Ministry of Transportation, 2020) may be implemented, if feasible. A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during construction. A comprehensive list of mitigation measures that will be implemented to limit dust deposition during construction is provided in the Atmospheric Environment Technical Support Document (**Appendix S**). Mitigation measures to limit dust deposition are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.3.3 Predicted Residual Effects

Effects on bird habitat availability and distribution from dust emissions are predicted to be larger during operations than during construction due to continuous use of the road by several hundred vehicles per day. Additionally, mitigation measures to limit dust emissions are predicted to be more effective during construction than during operations as construction traffic and equipment will be managed by owner / operators and more easily controlled, while, during operations, the Community Access Road will be used by public vehicles. Dust deposition, particularly during operations, is predicted to result in negligible but certain changes to vegetation quality in the effects assessment Local Study Area (Vegetation Technical Support Document [**Appendix J**]; Peatlands Technical Support Document [**Appendix I**]). As such, there is predicted to be a net residual effect on bird habitat availability and distribution from construction through operations. The residual effects from dust emissions were carried forward into the residual effects assessment characterization.

Effects from dust emissions are predicted to be **certain**, **reversible** in the **medium term** (construction) or **irreversible** (**long term**) (Operations), **continuous**, and confined to the **effects assessment Local Study Area**. Effects from dust emissions on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be **negative** but **negligible in magnitude**.

9.4.4.3.4 Changes to Birds from Erosion and Sedimentation

9.4.4.3.4.1 Potential Effects

Habitat Availability and Distribution

Construction activities such as watercourse crossings, vegetation clearing, earth moving, pit and quarry development and other Construction activities can result in exposure of vulnerable banks or slopes resulting in increased release of sediment. Sediment release into adjacent retained natural areas can have an effect on the composition and function of peatland and vegetation communities [Vegetation Technical Support Document (**Appendix J)**; Peatlands Technical Support Document (**Appendix I**)]. These changes can reduce or degrade bird habitat through localized changes in ecosystem composition. The effects on vegetation would be expected to be localized and occur intermittently during construction but could include vegetation smothering and changes to drainage patterns and infiltration in the area of sediment deposits.

9.4.4.3.4.2 Mitigation and Enhancement Measures

An environmental monitoring program will be developed and implemented during construction and will contain mitigation measures to control erosion and sedimentation. Erosion and sediment control measures will be developed and implemented in accordance with Ontario Provincial Standard Specifications for erosion and sediment control measures (Ministry of Transportation, 2021a, 2021c). Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

A comprehensive list of mitigation measures that will be implemented during construction is provided in Vegetation Technical Support Document (**Appendix J**) and Surface Water Technical Support Document (**Appendix F**). Mitigation measures to limit erosion and sedimentation are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.4.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**), construction of the Community Access Road could result in localized increase in erosion-sedimentation processes at locations upstream or downstream of watercourse crossings and at receiving waterbodies. Environmental protection and monitoring plans

developed for the Community Access Road construction are expected to limit erosion and sedimentation. Localized increases in erosion-sedimentation processes at locations upstream or downstream of watercourse crossings and at receiving waterbodies could also occur during operations. After implementing mitigation, the Community Access Road is not predicted to result in residual effects bird habitat, relative to existing conditions. As such, this interaction was not carried forward in the assessment.

9.4.4.3.5 Changes to Birds from Impacts to Surface Water Quantity

9.4.4.3.5.1 Potential Effects

Habitat Availability and Distribution

Construction activities such as constructing watercourse crossings, vegetation clearing, short-term water takings, and discharge of construction water can cause changes to stream flows and / or water levels within or immediately upstream and downstream of the work area. Changes in the volume or rate of surface water during construction of the Community Access Road may adversely affect soils, peatland, wetland, and riparian ecosystems through desiccation or inundation. Peatland, wetland, and riparian ecosystems experience water level fluctuations as part of natural variability and riparian ecosystems can recover relatively quickly from flooding.

Fluctuating surface water levels typically influence plant species composition, community structure, and species richness, and preventing changes in wetland water levels can cause a decrease in aquatic plant community diversity. Alternatively, changes in the amplitude, frequency, and timing of flood or drought compared to historical levels can cause adverse effects on wetlands, riparian areas, and peatlands. These changes can alter bird habitat availability and distribution through localized changes in ecosystem composition, particularly peatland, wetland, and riparian areas.

9.4.4.3.5.2 Mitigation and Enhancement Measures

Environmental approval conditions, permits, or authorizations issued for the Community Access Road, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during construction. A comprehensive list of mitigation measures to limit changes to surface water quantity during construction is provided in the Surface Water Technical Support Document (**Appendix F**). Mitigation measures to limit changes to surface water quantity are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.5.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**), changes to surface water quantity during the construction and operations phases are anticipated to be of negligible magnitude. As such, no net residual effects on bird habitat availability and distribution are predicted and this interaction is not carried forward into the assessment.

9.4.4.3.6 Changes to Birds from Impacts to Surface Water Quality

9.4.4.3.6.1 Potential Effects

Habitat Availability and Distribution

During construction, surface water may become contaminated if chemicals or substances (for example, petroleum products, sediments, and garbage) from project equipment, vehicles, road surfaces, or blasting sites are transported into surface water during precipitation events (Surface Water Technical Support Document [**Appendix F**]). This includes contamination of surface water from wash-off of organic debris during vegetation maintenance activities. Changes to surface water quality could have negative effects vegetation on bird habitat availability and distribution.

9.4.4.3.6.2 Mitigation and Enhancement Measures

Mitigation measures during construction of the Community Access Road include adherence to federal and provincial regulations and guidelines regarding collection and storage of explosives and solid waste, such as the federal Explosives Act. Additionally, during the winter periods of construction, sand will be used on the Community Access Road for de-icing instead of road salt, if required. Herbicides or pesticides will not be used at any stage of the Community Access Road construction. Environmental approval conditions, permits, or authorizations issued for the Community Access Road, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during construction. A comprehensive list of mitigation measures to limit changes to surface water quality during construction is provided in the Surface Water Technical Support Document (**Appendix F**). Mitigation measures to limit changes to surface water quality are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.6.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**), changes to surface water quality during construction are anticipated to be of negligible magnitude. As such, no net residual effects on bird habitat availability and distribution are predicted and this interaction is not carried forward into the assessment.

9.4.4.3.7 Changes to Birds from Impacts and Changes to Groundwater

9.4.4.3.7.1 Potential Effects

Habitat Availability and Distribution

If aggregates are extracted from below the water table at pits or quarries the local groundwater levels would be lowered either by active dewatering or dredging. Active dewatering of aggregate pits or quarries would likely take place using a sump to collect water in the bottom of the pit or quarry and pumping the water out of the sump to discharge outside the pit / quarry area. Dredging would lower groundwater levels to a lesser degree than dewatering.

Pit dewatering and dredging may result in changes to groundwater levels of more than 50 percent of the natural seasonal variability (in other words, high magnitude effect; Groundwater Technical Support Document; **Appendix H**). Effects are considered probable to occur (Groundwater Technical Support Document; **Appendix H**). However, effects are anticipated to be reversible soon after construction ends (in other words, medium term) and confined to the Groundwater Effects Assessment Local Study Area (in other words, 1 kilometres from centreline of Preferred Route and associated construction areas; Groundwater Technical Support Document; **Appendix H**).

Road construction using “floating” techniques to cross areas of peatland will be designed with a pervious road base structure to allow for the flow of groundwater beneath and through the road base. However, there is potential for settlement of the road base structure and underlying peat material or sediment accumulation in the road base material to restrict the flow of groundwater. If the groundwater flow is restricted to a substantial degree, then the road may cause a damming effect with elevated groundwater levels on the upgradient side of the road and lowered groundwater levels on the downgradient side.

Settlement of the road base structure and underlying peat material or sediment accumulation in the road base material may result in changes to groundwater quantity that are between 20 percent and 50 percent higher / lower than existing condition values (in other words, medium magnitude effect) (Groundwater Technical Support Document; **Appendix H**). Effects from road settlement or sediment accumulation during

construction are possible to occur, anticipated to be confined to the Groundwater Effects Assessment Local Study Area, and anticipated to be reversible in the long term with implementation of mitigation (Groundwater Technical Support Document; **Appendix H**).

Alteration of groundwater levels due to project activities could have negative effects on bird habitat availability and distribution, particularly for wetland-dependent birds. Changes to vegetation communities are anticipated to be of medium magnitude and probable to occur (Vegetation Technical Support Document [**Appendix J**]; Peatlands Technical Support Document [**Appendix I**]).

9.4.4.3.7.2 Mitigation and Enhancement Measures

Environmental approval conditions, permits, or authorizations issued for the Community Access Road, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during construction. A comprehensive list of mitigation measures to limit changes to groundwater quantity during construction is provided in the Groundwater Technical Support Document (**Appendix H**). The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.7.3 Predicted Residual Effects

With the implementation of the recommended mitigation measures, changes to groundwater regimes will be minimized and impacts to retained vegetation communities and bird habitat availability and distribution should be minimal. However, there are still anticipated to be measurable changes to vegetation due to change to groundwater quantity, which are predicted to result in a residual effect on bird habitat availability and distribution. As such, this interaction is carried forward to the residual effects characterization.

Effects from changes to groundwater quantity are predicted to be probable, irreversible (long term), continuous, and confined to the effects assessment Local Study Area. Effects from changes to groundwater quantity on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude.

9.4.4.3.8 Changes to Birds from Increase in Public Access

9.4.4.3.8.1 Potential Effects

Survival and Reproduction

Roads and access provide increased opportunities for humans to use an area, which can result in increased bird mortality from hunters and poachers and increased mortality of bird food sources (for example, fish) because linear features allow ease of access into previously inaccessible areas (Jalkotzy et al., 1997; Trombulak and Frissell, 2001). Indigenous Knowledge provided by Marten Falls First Nation included concerns related to effects on birds, bird habitat, and bird food sources as a result of increased public access and anthropogenic activities (for example, angling) (Marten Falls First Nation, 2023; MNP LPP, 2024b; Shared Value Solutions, 2024). One community member from Aroland First Nation noted the following regarding this potential effect, “The first thing I thought about was the wilderness, the animals would be disturbed. If the road goes through there, they’re travelling routes would be disrupted. And also, their feeding might be disrupted. As for the fish, I think if they build bridges and all that, it’s easier access for humans to go harvest. To me, that would be very destructive for the wildlife and fishery." (Shared Value Solutions, 2024). Concerns shared by Marten Falls First Nation discussed about how increased commercial and recreational fishing in the study areas might affect the food sources of bird species in the region (Marten Falls First Nation, 2023).

There is anticipated to be limited increase in public access during construction. However, a few individuals may illegally use constructed portions of the effects assessment Construction Disturbance Area to access areas that were previously inaccessible or more difficult to access for hunting or fishing.

9.4.4.3.8.2 Mitigation and Enhancement Measures

The following mitigation measures will be implemented during construction to limit effects from increases in public access:

- Restrict access to the effects assessment Construction Disturbance Area to construction personnel and prohibit firearms;
- Monitor central access corridors or have manned gate / security in place, during periods of high activity;
- Block winter roads and temporary access routes and trails that are no longer required; and
- Install access controls (for example, gates and boulders) to control public vehicle travel on some temporary access routes and trails.

The effectiveness of mitigation measures will be evaluated during and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.8.3 Predicted Residual Effects

Mitigation measures will be implemented to limit increases in public access during construction, and any increases in angler and hunting pressure during construction are anticipated to have no to minor impacts on birds and their food resources in the effects assessment Local and Regional Study Areas. As such, there is predicted to be no residual effect from increased access during construction.

9.4.4.3.9 Changes to Birds from Incidental Take

9.4.4.3.9.1 Potential Effects

Survival and Reproduction

The federal *Migratory Birds Convention Act*, 1994 and attendant Migratory Birds Regulation protect most migratory birds, their eggs, and nests. The modernized Migratory Birds Regulation, 2022 came into effect July 30, 2022, and protects nests of some species year-round, including pileated woodpecker. Pileated woodpecker nests are protected year-round for 36 months after last being used by any migratory bird that is protected under the Migratory Birds Regulation.

Raptors (for example, hawks and owls) are not protected under the *Migratory Birds Convention Act*, 1994; however, the *Fish and Wildlife Conservation Act* and attendant Wildlife Schedules protect several raptor species. Some raptor stick nests are protected from destruction as long as the nest is present; the nest does not have to be active to be protected.

Some birds are also protected under the federal *Species at Risk Act* and / or Ontario's *Endangered Species Act* and regulations. These acts protect residences (such as, nests) and individuals of species that are listed as "Extirpated," "Endangered," or "Threatened." Recommendations for listing under the *Species at Risk Act* come from the Committee on the Status of Endangered Wildlife in Canada, while recommendations for listing under the *Endangered Species Act* come from the Committee on the Status of Species at Risk in Ontario.

Eight species detected during existing conditions surveys are listed under the *Species at Risk Act* and / or the *Endangered Species Act*:

- Canada warbler ("Special Concern" under the *Endangered Species Act*; "Threatened" under the *Species at Risk Act* but under consideration for a status change);
- Common nighthawk ("Special Concern" under the *Endangered Species Act* and the *Species at Risk Act*);
- Eastern whip-poor-will ("Threatened" under the *Endangered Species Act* and the *Species at Risk Act* but under consideration for a status change under the *Species at Risk Act*);
- Eastern wood-pewee ("Special Concern" under the *Endangered Species Act* and the *Species at Risk Act*);
- Olive-sided flycatcher ("Special Concern" under the *Endangered Species Act* and the *Species at Risk Act*);
- Rusty blackbird ("Special Concern" under the *Endangered Species Act* and the *Species at Risk Act*);
- Yellow rail ("Special Concern" under the *Endangered Species Act* and the *Species at Risk Act*); and
- Lesser yellowlegs ("Threatened" under the *Endangered Species Act* and under consideration for listing under the *Species at Risk Act*).

Bird nests, eggs, and / or birds could be destroyed during land clearing and site preparation for construction. The ability of valued components to avoid or move away from construction activities can be extremely constrained during certain life history periods or stages. For example, although all adult bird valued components are extremely mobile, their nests, eggs, and fledglings are not. Direct removal of habitat during the nesting period can increase the risk of injury or mortality to adults and their young.

Removal of vegetation during construction of the Community Access Road may affect the survival and reproduction of a variety of bird species, as forested, wetland, shrub, and open habitats are anticipated to be disturbed during vegetation clearing activities.

9.4.4.3.9.2 Mitigation and Enhancement Measures

The migratory bird nesting season and timing of construction activities should be considered during the detail design and construction phases. It is estimated that 90

percent of species in nesting zones C5 and C6 will be actively nesting between April 28 and August 14 (Environment and Climate Change Canada, 2023c). Raptors, such as owls, nest earlier in year (from February through April). As such, during construction, clearing activities will occur between August 15 and April 27, outside the breeding season for most bird species, where possible. If any vegetation clearing is required during the migratory bird nesting season (April 28 to August 14; Environment and Climate Change Canada, 2023c), non-intrusive pre-clearing nest surveys will occur within seven days prior to clearing. If any areas are found to have birds exhibiting breeding behaviour, these areas, including an activity disturbance buffer, will be flagged and protected from disturbance until the fledglings have left the nest **Attachment D – Pre-Clearing Nest Sweep Protocol** of **Appendix L** provides a synopsis of the protocol of bird nest sweets.

Prior to site clearing, wildlife sweeps will also be completed outside of the nesting season to look for and document pileated woodpecker nesting cavities and raptor stick nests. Wildlife sweeps will be focused on mature and old growth forest dominated by deciduous trees as these habitats are most likely to have large trees that can support raptor stick nests and pileated woodpecker nests. Wildlife sweeps will be completed within 10 days prior to vegetation clearing. Raptor stick nests found during construction will be marked and isolated as Environmentally Sensitive Sites and setbacks from construction activities and / or staged construction activities will be implemented. If pileated woodpecker nest cavities are found during wildlife sweeps, the nests will be registered in the Abandoned Nest Registry and monitored for a minimum of 36 months to determine if the nests are actively being used by migratory birds. Any trees with pileated woodpecker nests will not be removed until they are determined to be inactive for at least 36 months after discovery.

The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.9.3 Predicted Residual Effects

The implementation of mitigation is anticipated to limit but not eliminate incidental take of migratory birds that may be nesting in the effects assessment Construction Disturbance Area. This is because it may not be possible to detect 100 percent of nests, particularly in complex forested habitat prior to site clearing for construction of the Community Access Road. As such there is a predicted net residual effect from the Project, and residual effects from incidental take were carried forward into the residual effects characterization.

Effects from incidental take are predicted to be possible, reversible in the medium term frequent and confined to the effects assessment Construction Disturbance Area. Effects from incidental take on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude.

9.4.4.3.10 Changes to Birds from Collisions with Vehicles and Equipment

9.4.4.3.10.1 Potential Effects

Survival and Reproduction

Birds may be killed by collisions with construction vehicles and equipment. Low-flying species, such as grouse, owls, eastern whip-poor-will, and common nighthawk, or species that forage on and near roads (for example, short-eared owl and bald eagle) may have higher risk of collisions with vehicles and equipment (Silva et al., 2012; Foley, 2018; Mathieu et al., 2021). Construction traffic levels, and therefore mortality risk, will be much lower than during operations.

9.4.4.3.10.2 Mitigation and Enhancement Measures

Mitigation measures that will reduce potential collisions with construction vehicles and equipment are:

- Incorporating standard safe road design configurations in the detail design phase;
- Micrositing the Community Access Road to avoid high-quality habitats and sensitive areas, to the extent feasible;
- Avoiding high-quality habitats and sensitive areas for migratory bird species at risk, to the extent feasible;
- Providing wildlife awareness training for road construction workers to reduce vehicle speeds;
- Restricting access to the Community Access Road to construction personnel during construction;
- Restricting construction traffic to designated areas; and
- Blocking winter roads and temporary access routes and trails no longer required as construction proceeds.

The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.10.3 Predicted Residual Effects

The implementation of mitigation is anticipated to limit Project-related changes to the survival and reproduction of birds from increased collision risk with vehicles and equipment. However, there is a predicted net effect from this interaction and, so, residual effects were carried forward into the residual effects characterization.

Effects from increased bird-vehicle collisions are predicted to be possible, reversible in the medium term, frequent and confined to the effects assessment Construction Disturbance Area. Effects from increased bird-vehicle collisions during construction on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude.

9.4.4.3.11 Changes to Birds from Wildlife Attractants

9.4.4.3.11.1 Potential Effects

Survival and Reproduction

Food smells and other aromatic compounds such as petroleum-based chemicals, grey water, and sewage could attract carnivores to temporary construction camps (Beckmann and Lackey, 2008; Canadian Wildlife Service, 2007; Peirce and Van Daele, 2006). Corvids and raptors may also be attracted to structures that can be used as hunting perches (for example, buildings and material stockpiles), and anthropogenic food sources at temporary construction staging areas and temporary construction camps (Baxter and Allan, 2008; Marzluff and Neatherlin, 2006; Restani et al., 2001; Fleming and Bateman, 2018).

Additionally, some bird species may use construction infrastructure and equipment as nesting habitat. For example, some bird species (such as, barn swallow) may use buildings that are present during construction (for example, camp buildings) and bridges as nesting habitat. Other species (such as, bank swallow) may use material stockpiles (for example, sand stockpiles) as nesting habitat. The use of infrastructure or equipment for nesting could result in inadvertent disturbance or destruction of bird nests by Community Access Road staff.

9.4.4.3.11.2 Mitigation and Enhancement Measures

The following mitigation will be implemented to deter birds from nesting on infrastructure during construction:

- Keeping building and storage container doors closed;

- Tarping or fully wrapping structures that have nesting potential (for example, camp buildings and shipping containers). It is important to avoid using nets or other cover types that could entangle birds and cause potential injury or mortality;
- Sealing cracks and holes where birds can enter structures;
- Place pallets and other small pieces of equipment low to the ground;
- Keeping heavy equipment free of mud, as mud can attract birds, particularly swallows, which use mud to build nests;
- Conducting frequent inspections of structures and equipment for evidence of birds, ideally every day during the nesting season, at dawn and dusk when birds are most active;
- The slopes of material stockpiles will be maintained at 70 degrees or less to deter bank swallow nesting;
- Hanging brightly coloured strips of fabric over slope faces to deter birds. These must be well secured and weighted at the bottom; and
- Placing geotextile, plastic covers, or tarping over slope faces or stockpiles to prevent access by birds. It is important to avoid using nets or other cover types that could entangle birds and cause potential injury or mortality.

Prepare an environmental monitoring program that will include policies and actions for handling and storage of waste as well as management of materials and stockpiles. The effects assessment Construction Disturbance Area would be kept clear of any attractants such as food scraps and food containers. Food waste will be collected and temporarily stored in wildlife-proof containers. The containers will be transported off site for recycling or disposed at a licensed disposal facility.

Mitigation measures to remove wildlife attractants are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.11.3 Predicted Residual Effects

Mitigation should limit wildlife attractants and attraction of birds and their predators to the Community Access Road. However, attraction could still occur. As such, this Project–environment interaction was predicted to have a net residual effect on bird populations and was carried forward into the residual effects characterization.

Effects are predicted to be **possible**, **irreversible** (**long term**) (for example, permanent aggregate piles and culverts), **continuous**, and confined to the **effects assessment Construction Disturbance Area**. Effects from wildlife attractants on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be **negative** but **negligible in magnitude**.

9.4.4.3.12 Changes to Birds from Blasting and Flying Rock

9.4.4.3.12.1 Potential Effects

Survival and Reproduction

During construction, explosives will be used at quarry sites to excavate materials for use during construction and to remove bedrock or large boulders in the right-of-way. Blasting activities may produce fly rock that has the potential to strike birds in the vicinity and cause injury or death. The risk of mortality from being struck by fly rock would be greatest for birds who occupy territories that overlap blasting sites, or for birds that are flying over blasting sites when blasting occurs.

9.4.4.3.12.2 Mitigation and Enhancement Measures

The presence of operating equipment, people, noise, and lights during construction is expected to result in some avoidance of the effects assessment Construction Disturbance Area by birds. An Environmental Protection Plan and Blasting and Communication Management Plan will be prepared and implemented during construction and will include policies and actions for avoiding and minimizing the risks of blasting and blasting materials to wildlife including birds. Industry best practices will be used for blasting activities, including adherence to Ontario Provincial Standard Specification 120 and NPC-119 (Final Acoustic and Vibration Technical Support Document [**Appendix P**]). Blasting will be completed as quickly as possible to shorten the duration of disturbance.

Quarry blasting and other construction activities will be suspended within 10 kilometres of known or potential High Use Areas during the migratory bird breeding season (April 28 to August 14) (Environment and Climate Change Canada, 2023c). If adherence to the timing windows and restrictions is not possible, the owner / operator will develop site-specific mitigation and monitoring in consultation with appropriate regulatory agencies. This may include implementation of a buffer zone survey around the perimeter of blasting activities and surrounding forested habitat, whereby blasting will be prohibited if raptor stick nests are observed within 500 metres from the blasting location.

An environmental monitoring program will be prepared and implemented during construction and will include policies and actions for avoiding and minimizing the risks of blasting and blasting materials to wildlife including birds. Best management practices will be included in the environmental monitoring program and at a minimum will include recommendations for pre-blast surveys for migratory birds, bird nest sweeps, habitat assessments for migratory birds, and noise and vibration control (for example, using smaller, more controlled charges, or staggering blasting etc.).

The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.12.3 Predicted Residual Effects

Due to the infrequent timing of blasting, and with the implementation of mitigation, blasting and fly rock from the Community Access Road during construction is not expected to result in injury or mortality to birds. There is no net effect predicted for this Project–environment interaction on bird survival and reproduction. Therefore, this interaction was not carried forward in the assessment.

9.4.4.3.13 Changes to Birds from Chemical or Hazardous Material Spills

9.4.4.3.13.1 Potential Effects

Survival and Reproduction

During construction of the Community Access Road, there is the potential for accidental spills of fuels and other materials resulting in the release of deleterious substances and soil contamination from malfunctions of equipment such as hydraulic and fluid leaks, spills during equipment or vehicle refuelling, and from vehicle collisions. Spills that occur in high enough concentrations can contaminate soils and affect aquatic organisms, soil organisms, vegetation, and wildlife, including birds. Direct exposure to the chemical through ingestion of contaminated water, soil or vegetation could result in acute or chronic illness or death. As a result, there is potential that construction of the Community Access Road could cause chemical / hazardous material spills that could negatively affect the survival and reproduction of bird populations in the Bird effects assessment Local Study Area. More information on potential effects from chemical or hazardous material spills on surface water and groundwater quality is presented in the Surface Water Technical Support Document (**Appendix F**) and Groundwater Technical Support Document (**Appendix H**).

9.4.4.3.13.2 Mitigation and Enhancement Measures

Mitigation measures during construction of the Community Access Road include adherence to federal and provincial regulations and guidelines regarding fuel and residue, chemical product, petroleum product, and hazardous substance collection and storage, use and handling, and disposal and treatment, such as the federal *Transportation of Dangerous Goods Act*, Ontario *Dangerous Goods Handling and Transportation Act* (Government of Ontario, 1990a), and the Ontario *Environmental Protection Act* (Government of Ontario, 1990b). Additionally, an environmental monitoring program will be developed and implemented and will include policies and actions for limiting effects from spills on bird habitat.

A comprehensive list of mitigation measures to limit changes to surface water and groundwater quality from spills during construction is provided in the Surface Water Technical Support Document (**Appendix F**) and the Groundwater Technical Support Document (**Appendix H**). Mitigation measures to limit chemical or hazardous material spills are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.13.3 Predicted Residual Effects

As discussed in the Vegetation Technical Support Document **(Appendix J**), Peatlands Technical Support Document (**Appendix I**), Surface Water Technical Support Document (**Appendix F**), Groundwater Technical Support Document (**Appendix H**), and Physiography, Terrain, and Soils Technical Support Document (**Appendix N**), there are predicted to be no residual effects from chemical or hazardous material spills on surface water quality, groundwater, soil, or vegetation quality during the construction and operations phases. As such there was predicted to be no net effect on bird survival and reproduction, relative to existing conditions. Therefore, the potential effects of chemical or hazardous material spills were not carried forward in the assessment.

9.4.4.3.14 Changes in Individual Bird Species

Information on individual bird species assessed can be found in Birds Technical Support Document (Appendix L). The following bird species were assessed:

- Forest Birds: Red-eyed Vireo, Oven bird, Dark-eyed Junco
- Raptors: Osprey, Boreal Owl
- Shorebirds: Wilson’s Snipe
- Waterfowl and Waterbirds: Mallard

- Bog / Fen Birds and Other Wetland Birds: Palm Warbler, Common Yellowthroat, Northern Waterthrush, Sora
- Species at Risk Birds: Canada Warbler, Evening Grosbeak, Chimney Swift, Bank Swallow, Barn Swallow, Common Nighthawk, Eastern Whip-poor-will, Eastern Wood-pewee, Olive-sided Flycatcher, Bald Eagle, Peregrine Falcon, Short-eared Owl, Black Tern, Lesser Yellowlegs, Rusty Blackbird, Yellow Rail

9.4.4.3.14.1 Potential Effects

Habitat Loss and Alteration

Habitat Availability

Vegetation clearing for the Community Access Road during construction is predicted to remove areas of high suitability and moderate suitability bird breeding habitat. High and moderate suitability habitat remains abundant in the effects assessment Regional Study Area. The Bird Technical Supporting Document (Appendix L) includes details on predicted habitat loss for each individual species listed.

Distribution

There is a higher proportion of high suitability habitat in the effects assessment Construction Disturbance Area (approximately 50 percent of the study area) than in the effects assessment Local Study Area and effects assessment Regional Study Area (approximately 40 percent of each study area). This is due to the selection of upland habitat for the Preferred Route.

It is anticipated that moderate and high suitability habitat in the effects assessment Regional Study Area is below carrying capacity for birds. As such, during construction of the Community Access Road, individuals returning during spring migration that previously used habitats in the effects assessment Construction Disturbance Area are expected to establish breeding territories in suitable habitat outside of the effects assessment Construction Disturbance Area.

In addition to the change in location of some breeding territories, the creation of a linear disturbance may cause birds in the effects assessment Local Study Area to shift their territories away from the effects assessment Construction Disturbance Area. A study in the boreal forest of the Northwest Territories found that some passerine bird species move their territories away from human linear disturbance features (Machtans, 2006).

After implementation of the Community Access Road, there are 252.2 kilometres of linear disturbance in the effects assessment Local Study Area and 309.0 kilometres of linear disturbance in the effects assessment Regional Study Area. Permanent

components are the Community Access Road and the access roads to aggregate pits (total 249.4 kilometres); non-permanent components are camp access roads (total 2.8 kilometres).

After implementation of the Community Access Road, the linear disturbance density for permanent and non-permanent linear disturbances (combined) in the effects assessment Local Study Area increases from is 0.17 kilometres / square kilometres (existing conditions) to <0.00 kilometres per square kilometre. Linear disturbance density in the effects assessment Regional Study Area increases from and 0.04 kilometres / square kilometres (existing conditions) to 0.06 kilometres / square kilometres.

The effects assessment Construction Disturbance Area may act also as a barrier to birds movements during foraging (Norris and Stutchbury, 2001; Fraser and Stutchbury, 2004; MacIntosh et al., 2011) and dispersal (Tittler et al., 2009). The effects assessment Construction Disturbance Area is assumed to be wider than the proposed corridor; vegetation will be permanently cleared within a 60-metre wide corridor. Also, there is a large amount of undisturbed habitat in the effects assessment Regional Study Area that remains available for birds. As such, overall movement patterns of birds in the effects assessment Regional Study Area are expected to remain unchanged with the addition of the Community Access Road.

The removal of habitat due to the Construction of the Project is predicted to result in a change to the distribution of bird breeding territories and movements in the effects assessment Regional Study Area.

Survival and Reproduction

Habitat loss from Construction of the Community Access Road could affect bird survival and reproduction if individuals return to breeding grounds to find habitat removed and subsequently are unable to establish a new territory or are forced to establish a territory in lower quality habitat. Construction of the Community Access Road is predicted to remove high and moderate suitability habitat that is available in the effects assessment Regional Study Area during existing conditions.

Sensory Disturbance

Habitat Availability

Sensory disturbance (for example, presence of workers and noise from construction equipment) during construction of the Community Access Road could result in the indirect loss or degradation of suitable bird habitat if individuals avoid areas with sensory disturbance. As the precise threshold of avoidance by birds due to sensory

disturbance is not known, habitat that was within 300 metres of the Community Access Road was assumed to be negatively affected by sensory disturbance as a precautionary approach.

During construction, activities will be primarily confined to daylight hours and will be of relatively short duration (in other words, confined to the start and end of Construction of each road segment). Additionally, effects from sensory disturbance during construction will be confined to when birds are present in the effects assessment Local Study Area (in other words, during the migration and breeding seasons).

Distribution

Sensory disturbance during construction may have a negative effect on bird movements and habitat connectivity if individuals avoid areas with sensory disturbance. Sensory disturbance effects during construction will be lower than during operations. During construction, sensory disturbance is expected to primarily occur during the day and will occur for relatively short durations at one location (in other words, confined to the start and end of construction of road segments). After construction of a road segment is complete, sensory disturbance at that location will be relatively low until road Operations commence.

Survival and Reproduction

The effects of noise on the survival and reproduction of birds are unknown but noise levels above 48 decibels have been shown to reduce abundance and pairing success of some songbird species (Habib et al., 2007; Bayne et al., 2008). Other potential effects from noise include interference with communication (for example, reducing ability to hear intraspecific vocalizations) and increased risk of predation (for example, reducing ability to hear approaching predators) (Ortega, 2012). Environment and Climate Change Canada (2023d) indicates that noise levels greater than 50 decibels or 10 decibels above ambient (background) noise can negatively affect birds.

Noise levels (existing conditions + Community Access Road) will reach 50 A-weighted decibels at 600 metres from the edge of the effects assessment Construction Disturbance Area during road and bridge construction. Noise levels at quarries during construction will reach 50 A-weighted decibels at 1,000 metres from the edge of the effects assessment Construction Disturbance Area (Acoustic and Vibration Environment Technical Support Document [**Appendix P**]).

During construction, sensory disturbance will primarily occur during the day; nighttime construction will be limited. Sensory disturbance during construction will occur for relatively short durations at one location (in other words, confined to the start and end of construction of road segment).

Increase in Edge Habitat

Survival and Reproduction

Vegetation removal during construction will result in increased edge habitat in forested areas and could have negative effects on bird survival and reproduction. Mitigation measures that will be implemented to minimize direct loss of forested vegetation communities, and therefore limit increases in edge habitat, are discussed in detail in the Vegetation Technical Support Document (**Appendix J**).

The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.3.14.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

Vegetation removal during construction will result in the direct loss of upland vegetation communities and result in changes to bird habitat availability, distribution, and survival and reproduction. Mitigation measures that will be implemented to minimize direct loss of upland vegetation communities are discussed in detail in the Vegetation Technical Support Document (**Appendix J**). These mitigations include:

- Limit the Community Access Road footprint to the extent feasible;
- Use existing access roads where possible; and
- Where possible, decommission and rehabilitate temporary access roads, staging areas, camps, and debris and / or timber stockpiles following Construction.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources will be followed during construction. The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

Sensory Disturbance

The following mitigation measures will be implemented to limit effects from sensory disturbance during construction on birds:

- Complete work as quickly as possible to shorten the duration of disturbance;

- The migratory bird nesting season and timing of activities should be considered during construction. Clearing activities should occur from August 15 to April 27 (outside the migratory bird nesting season); if any clearing is required during the breeding bird season, non-intrusive pre-clearing nest surveys will occur within seven days of the clearing; buffers will be established around each nest, and clearing activities will be restricted near active bird nests or pileated woodpecker nest cavities;
- Follow guidance as outlined in Environment and Climate Change Canada's Avoidance Guidelines for Migratory Birds;
- Surveys will be conducted for ecologically sensitive sites prior to Construction; marking, isolation and setbacks implemented if these sites are found;
- Control lighting required for construction of the Community Access Road, including direction (for example, focused on work areas and away from undisturbed areas) and timing (for example, minimize work at night) to minimize effects on birds, while meeting health and safety requirements;
- Wildlife awareness training will be provided for road construction workers to reduce vehicle speeds and associated noise and dust emission levels;
- Restricting construction traffic to designated areas;
- Industry best practices will be used for blasting activities, including scheduling outside of sensitive periods when in the vicinity of sensitive wildlife sites;
- Multi-passenger vehicles (for example, buses) will be used to transport workers to site when practicable; and
- Environmental approval conditions, permits, or authorizations issued for the Community Access Road, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

Increase in Edge Habitat

The construction of the Community Access Road will increase the amount of edge habitat, relative to existing conditions, and effects from changes to predator communities and increased predation risk will occur throughout construction. The

implementation of mitigation and enhancement measures is expected to limit negative effects but there is a predicted net residual effect on bird survival and reproduction.

9.4.4.3.14.3 Predicted Residual Effects

Habitat Loss and Alteration

Even after mitigation, potential breeding habitat will be removed by the Community Access Road. Habitat loss will initially occur during construction. The implementation of mitigation and enhancement measures is expected to limit negative effects. However, there are predicted net residual effects on bird habitat availability, distribution, and survival and reproduction during construction.

Residual effects from habitat loss on the ability of the bird population in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but low in magnitude. As such, this Project–environment interaction is carried forward to the cumulative effects. These predicted residual effects are applicable to Red-eyed Vireo, Ovenbird, Dark-eyed Junco, Osprey, Boreal Owl, Wilson's Snipe, Mallard, Palm Warbler, Common Yellowthroat, Northern Waterthrush, Sora, Canada Warbler, Evening Grosbeak, Chimney Swift, Barn Swallow, Bank Swallow, Common Nighthawk, Eastern Whip-poor-will, Eastern Wood-Pewee, Olive-sided Flycatcher, Bald Eagle, Peregrine Falcon, Short-eared Owl, Black Tern, Lesser Yellowlegs, Rusty Blackbird and Yellow Rail.

Sensory Disturbance

Even after implementation of mitigation, potential bird breeding habitat may be indirectly removed or degraded due to sensory disturbance during construction of the Community Access Road. As such, there are predicted net residual effects on bird habitat availability, distribution, and survival and reproduction during construction.

Residual effects from sensory disturbance on the ability of the bird population in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but low in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects. These predicted residual effects are applicable to Red-eyed Vireo, Ovenbird, Dark-eyed Junco, Osprey, Boreal Owl, Wilson's Snipe, Mallard, Palm Warbler, Common Yellowthroat, Northern Waterthrush, Sora, Canada Warbler, Evening Grosbeak, Chimney Swift, Barn Swallow, Bank Swallow, Common Nighthawk, Eastern Whip-poor-will, Eastern Wood-Pewee, Olive-sided Flycatcher, Bald Eagle, Peregrine Falcon, Short-eared Owl, Black Tern, Lesser Yellowlegs, Rusty Blackbird and Yellow Rail.

Increase in Edge Habitat

The Construction of the Project will increase the amount of edge habitat, relative to existing conditions, and effects from changes to predator communities and increased predation risk will occur throughout Construction and Operations. The implementation of mitigation and enhancement measures is expected to limit negative effects but there is a predicted net residual effect on bird survival and reproduction.

Effects from increased edge habitat are predicted to be probable to occur, irreversible (long term), continuous, and confined to the effects assessment Local Study Area.

Residual effects from increased edge habitat on the ability of the bird population in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but low in magnitude. As such, this Project–environment interaction is carried forward to the Cumulative Effects Assessment for birds. These predicted residual effects are applied to Red-eyed Vireo, Ovenbird, Palm Warbler, Northern Waterthrush, Common Nighthawk, Eastern Whip-poor-will and Short-eared Owl.

9.4.4.4 Residual Effects – Operations

9.4.4.4.1 Changes to Birds through the Introduction of Invasive Plant Species

9.4.4.4.1.1 Potential Effects

During the Operation Phase, regular vehicle traffic on the Community Access Road could transport invasive plant seeds or plant parts into the effects assessment Construction Disturbance Area. Effects from the introduction and spread of invasive plants during operations would be the same as for Construction (see section above). If invasive plant species are introduced and spread within the effects assessment Construction Disturbance Area, this could degrade the quality of habitats used by birds (for example, suitable foraging habitat), ultimately reducing the availability and distribution of suitable habitat during the Operation Phase.

9.4.4.4.1.2 Mitigation and Enhancement Measures

As per the Ministry of Transportation's Weed Control Maintenance Best Practice (MBP-320), invasive plant species in the effects assessment Construction Disturbance Area will be controlled using a combination of biological, cultural, manual, and mechanical control methods during operations (Ministry of Transportation, 2003). Herbicides or pesticides will not be used during the Community Access Road operations phases.

A comprehensive list of mitigation measures to control invasive plant species during operations is provided in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I**).

9.4.4.4.1.3 Predicted Residual Effects

Invasive plant species may occasionally be introduced within the effects assessment Construction Disturbance Area during Operations. Introduction of invasive plant species may be higher during Operations due to public use of the Community Access Road. As such, the Project is expected to have net residual effects on birds and their habitats, relative to existing conditions and this interaction was carried forward into the residual effects characterization.

Effects from the introduction of invasive plants on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude. This Project-environment interaction was not carried forward to cumulative effects.

9.4.4.4.2 Changes to Birds from Emissions of Criteria Air Contaminants

9.4.4.4.2.1 Potential Effects

During the Operation Phase of the Project, emissions would be generated mainly from the use of fossil fuels associated with vehicle use of the Project and road maintenance (general, seasonal, and special maintenance). As discussed in the Atmospheric Environment Technical Support Document (**Appendix S**), air criteria contaminants were predicted to be below Canadian Ambient Air Quality Standards and / or Ontario Ambient Air Quality Criteria thresholds during the Operation Phase.

9.4.4.4.2.2 Mitigation and Enhancement Measures

A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during Maintenance. A comprehensive list of mitigation measures that will be implemented to limit air particulate emissions during Operations is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).

9.4.4.4.2.3 Predicted Residual Effects

As discussed in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I**), emissions of criteria air contaminants are anticipated to have negligible, possible effects on vegetation ecosystems, and, ultimately, bird habitat. As such, this interaction was determined to

have no residual effects on bird habitat availability and distribution and is not carried forward in the assessment.

9.4.4.4.3 Changes to Birds from Fugitive Dust Emissions

9.4.4.4.3.1 Potential Effects

Habitat Availability and Distribution

Fugitive dust emissions are expected to be produced during Operations from activities such as travel on the gravel Community Access Road. Potential effects from fugitive dust emissions on bird habitat availability and distribution are outlined in the Construction section above.

During Operations, threshold exceedances for the Project are predicted for particulate matter less than 2.5 micrometres, particulate matter less than 10 micrometres and total suspended particulate. The particulate matter less than 2.5 micrometres levels are predicted to reach the 24-hour and annual criteria thresholds at 115 metres and 134 metres from the road, respectively. Levels of particulate matter less than 10 micrometres are predicted to reach the 24-hour threshold at 1,986 metres from the road. Emissions of total suspended particulate are predicted to reach the 24-hour and annual thresholds at 3,004 metres and 899 metres from the road, respectively.

9.4.4.4.3.2 Mitigation and Enhancement Measures

A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during Operations. A comprehensive list of mitigation measures that will be implemented to limit dust deposition during operations is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).

9.4.4.4.3.3 Predicted Residual Effects

Effects on bird habitat availability and distribution from dust emissions are predicted to be larger during Operations due to continuous use of the road by several hundred vehicles per day. Additionally, mitigation measures to limit dust emissions are predicted to be less effective during Operations, the Community Access Road will be used by public vehicles. Dust deposition, particularly during Operations, is predicted to result in negligible but certain changes to vegetation quality in the effects assessment Local Study Area (Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I**).]). As such, there is a predicted net residual effect on bird habitat availability and distribution through the operations phase. The

residual effects from dust emissions were carried forward into the residual effects assessment characterization.

Effects from dust emissions are predicted to be certain, irreversible (long term) (Operations), continuous, and confined to the effects assessment Local Study Area. Effects from dust emissions on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects.

9.4.4.4.4 Changes to Birds from Erosion and Sedimentation

9.4.4.4.4.1 Potential Effects

Habitat Availability and Distribution

Erosion and release of sediments in watercourses and adjacent terrestrial habitat may also occur during operations. Large precipitation events may lead to run-off from the road and sedimentation in low lying areas such as wetland and riparian habitats. Similar to Construction, the effects would be localized, intermittent and variable throughout the year.

9.4.4.4.4.2 Mitigation and Enhancement Measures

An environmental monitoring program will be developed and implemented during Maintenance and will contain mitigation measures to control erosion and sedimentation. Similar to Construction, erosion and sediment control measures will be developed and implemented in accordance with Ontario Provincial Standard Specifications for erosion and sediment control measures (Ministry of Transportation, 2021a, 2021c) during operations. Additionally, mitigation identified in the Ministry of Transportation's Maintenance Quality Standards and Maintenance Best Practices for highway maintenance (Ministry of Transportation, 2003) will be implemented to minimize erosion and sedimentation during operations. The mitigation measures established and refined using adaptive management during Project Construction should be maintained during operations.

A comprehensive list of mitigation measures that will be implemented during Operations is provided in Vegetation Technical Support Document (**Appendix J**) and Surface Water Technical Support Document (**Appendix F**).

9.4.4.4.4.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**) localized increases in erosion-sedimentation processes at locations upstream or downstream of watercourse crossings and at receiving waterbodies could also occur during Operations. After implementing mitigation, the Project is not predicted to result in residual effects bird habitat, relative to existing conditions. As such, this interaction was not carried forward in the assessment.

9.4.4.4.5 Changes to Birds from Impacts to Surface Water Quantity

9.4.4.4.5.1 Potential Effects

Habitat Availability and Distribution

Conversion of treed and peatland habitats to open or shrubby habitats could result in changes to surface water quantity during Operations of the Community Access Road (Surface Water Technical Support Document; **Appendix F**).

9.4.4.4.5.2 Mitigation and Enhancement Measures

The mitigation measures established and refined using adaptive management during Project Construction should be maintained during Operations. Follow Ontario Provincial Standard Specification 411 and regularly inspect and maintain culverts and bridges. Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during Operations. A comprehensive list of mitigation measures to limit changes to surface water quantity during operations is provided in the Surface Water Technical Support Document (**Appendix F**).

9.4.4.4.5.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**), changes to surface water quantity during Operations are anticipated to be of negligible magnitude. As such, no net residual effects on bird habitat availability and distribution are predicted and this interaction is not carried forward into the assessment.

9.4.4.4.6 Changes to Birds from Impacts to Surface Water Quality

9.4.4.4.6.1 Potential Effects

Habitat Availability and Distribution

During Operations, contamination of surface water may occur from garbage (Surface Water Technical Support Document; **Appendix F**).

9.4.4.4.6.2 Mitigation and Enhancement Measures

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during Operations. During the winter periods, sand will be used on the Community Access Road for de-icing instead of road salt. Herbicides or pesticides will not be used during the Community Access Road during operations. The mitigation measures established and refined using adaptive management during Project Construction should be maintained during operations. A comprehensive list of mitigation measures to limit changes to surface water quality during operations is provided in the Surface Water Technical Support Document (**Appendix F**).

9.4.4.4.6.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**), changes to surface water quality during Operations are anticipated to be of negligible magnitude. As such, no net residual effects on bird habitat availability and distribution are predicted and this interaction is not carried forward into the assessment.

9.4.4.4.7 Changes to Birds from Impacts and Changes to Groundwater

9.4.4.4.7.1 Potential Effects

Effects from changes to groundwater levels on bird habitat availability and distribution from the potential settlement of the road base structure and underlying peat material, and from potential sediment accumulation in the road base material restricting the flow of groundwater, may continue through Operations of the Community Access Road.

9.4.4.4.7.2 Mitigation and Enhancement Measures

The mitigation measures established and refined using adaptive management during construction should be maintained during Operations. Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from

Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during Operations. As discussed in the Groundwater Technical Support Document (**Appendix H**) the mitigation measures established and refined using adaptive management during construction should be maintained during Operations. It is expected that a robust monitoring program will be undertaken, and adaptive management measures implemented, as required. This monitoring program is described in more detail in the Peatlands Technical Support Document (**Appendix I**).

9.4.4.4.7.3 Predicted Residual Effects

With the implementation of the recommended mitigation measures, changes to groundwater regimes will be minimized and impacts to retained vegetation communities and bird habitat availability and distribution should be minimal. However, there are still anticipated to be measurable changes to vegetation due to change to groundwater quantity, which are predicted to result in a residual effect on bird habitat availability and distribution. As such, this interaction is carried forward to the residual effects characterization.

Effects from changes to groundwater quantity are predicted to be probable, irreversible (long term), continuous, and confined to the effects assessment Local Study Area. Effects from changes to groundwater quantity on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects.

9.4.4.4.8 Changes to Birds from Increase in Public Access

9.4.4.4.8.1 Potential Effects

During Operations, the Community Access Road is likely to increase access for hunters and anglers in the Birds effects assessment Local and Regional Study Areas.

There is a hunting season for waterfowl (for example, ducks and geese), grouse and allies (for example, ptarmigan [Oji-Cree translation, wabihse] [Lagopus spp.]), American coot (Fulica americana), and Wilson’s snipe (Gallinago delicata) in the Effects Local and Regional Study Areas. The hunting of waterfowl, Wilson’s snipe, and American coot is regulated by Environment and Climate Change Canada under the Migratory Birds Conservation Act, while the hunting of grouse and allies is regulated by the Ontario Ministry of Natural Resources.

Indigenous Knowledge shared by communities including Aroland First Nation, Constance Lake First Nation, Fort Albany First Nation, and Marten Falls First Nation have identified that birds including geese, duck, ruffed grouse are traditional food sources and are hunted by community members (Fort Albany First Nation, 2020; LeBlanc, 2014; Marten Falls First Nation, 2023; Stantec, 2017b). Aroland First Nation has also noted that there has been a shift from local to processed foods, as well as from harvested to purchased foods in recent years (LeBlanc, 2014).

Within Marten Falls First Nation, a cultural week-long break is often taken each year (usually at the end of April), by community members to participate in hunting activities and celebrations surrounding the harvest of waterfowl (Dillon, 2026). Indigenous Knowledge provided by Constance Lake First Nation and Marten Falls First Nation also identified that Kenogamisis Lake, Kenogamisis River, Goldfield Lake, the Albany River rapids, and nearby connecting waterbodies are areas of importance for some bird species, in particular, ducks and ruffed grouse (Marten Falls First Nation, 2023; Stantec, 2017a,b).

During Operations, increased fish harvest may decrease the productivity of fish populations, but it is not likely to disrupt overall population dynamics and fish populations are anticipated to remain functional, self-sustaining, and ecologically effective. Increase in harvest pressure is mainly expected to be on larger waterbodies with known productive fisheries (Fish and Fish Habitat Technical Support Document; **Appendix G**). As such, changes to prey resources from the Project are not predicted have a measurable effect on the survival and reproduction of fish-dependent bird species (for example, osprey and bald eagle).

There is currently a small risk of human-caused mortality or changes to bird food resources from increased public access / hunting of birds in the effects study areas due to the isolation of the Project and the small human population in northern Ontario. The Project is likely to facilitate human access to the Local and Regional Effects Study Areas, which may result in increased fishing, and hunting and illegal harvesting of birds. However, the distance of the Project from the nearest large urban centre, inaccessible terrain, and the lack of roads and trails throughout most of the effects assessment Local Study Area and Regional Study Area is expected to limit increases in the number of anglers, hunters, and poachers that may access via the Project.

9.4.4.4.8.2 Mitigation and Enhancement Measures

The following mitigation measures will be implemented during Operations to limit effects from increases in public access:

- Potential changes in hunter and angler pressure, and fish and bird harvest will continue to be managed by Environment and Climate Change Canada, Ministry of Natural Resources, and Fisheries and Oceans Canada through licensing requirements and by establishing rules in terms of season length, bag / catch limits, and catch-and-release rules for waterbodies near the Project. Local communities will be responsible for managing their resources by limiting fish catch to a sustainable level for each species.

9.4.4.4.8.3 Predicted Residual Effects

The Project may increase hunting, fishing, and poaching during Operations, relative to existing conditions. There are currently no plans to decommission the Community Access Road and effects from increased public access are expected over the life of the Project. As such, there is a predicted net residual effect on bird survival and reproduction, relative to existing conditions and this interaction was carried forward into the residual effects characterization.

Effects from increases in public access are predicted to be possible, irreversible (long term), continuous, and confined to the effects assessment Regional Study Area. Effects from increased hunting and poaching on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects.

9.4.4.4.9 Changes to Birds from Incidental Take

9.4.4.4.9.1 Potential Effects

Survival and Reproduction

Bird nests, eggs, and / or birds could be destroyed during vegetation control activities in roadside ditches and rest areas during Operations. As per the Ministry of Transportation's Brush Control Maintenance Quality Standard (MQS-324) and Grass Control Maintenance Quality Standard (MQS-326), for roads with an 80 kilometres per hour speed limit, such as that proposed for the Project, mowing and brush clearing are required within 185 metres of road signs and other objects that need to be seen (for example, guide rails) (Ministry of Transportation, 2003). During operations, inspections of the road and rest areas will occur two days of each week and, based on these

inspections, mowing will be completed to maintain vegetation below 2 metres in height (Ministry of Transportation, 2003). As per the Ministry of Transportation's Rest Area/Picnic Site Maintenance Best Practice (MBP-325) and Tree Control Maintenance Best Practice (MBP-321), the weekly highway and rest area inspections will also note any trees that may need to be pruned or remove to maintain road and rest area safety.

Tree pruning and removal will occur throughout spring, summer, and fall, while mowing is expected to start in June or July and continue through September. Pruning and removal of hazardous trees during operations may negatively affect the survival and reproduction of tree-nesting species. Mowing of roadside ditches and rest areas is predicted to primarily affect the survival and reproduction of ground-nesting birds that require open, grassy habitats (for example, mallard).

9.4.4.4.9.2 Mitigation and Enhancement Measures

The migratory bird nesting season and timing of activities should be considered during Maintenance. As per the Ministry of Transportation's Environmental Protection for Migratory Birds (EP-4) (Ministry of Transportation, 2003), bridges and culverts will be inspected for the presence of birds and / or nests prior to maintenance activities commencing. If an active nest is found on a culvert or bridge, a Migratory Bird (Damage) Permit must be obtained for the nest. Depending on the species and if there are no young birds in the nest, the nest may be removed under the Permit after it is obtained.

9.4.4.4.9.3 Predicted Residual Effects

The implementation of mitigation is anticipated to limit but not eliminate incidental take of migratory birds that may be nesting in the effects assessment Construction Disturbance Area. There is potential for incidental take of migratory birds if vegetation clearing or mowing during Operations is completed during the migratory bird nesting season. As such there is a predicted net residual effect from the Project, and residual effects from incidental take were carried forward into the residual effects characterization.

Effects from incidental take are predicted to be possible, irreversible in the long term, infrequent (Operations), and confined to the effects assessment Construction Disturbance Area. Effects from incidental take on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects.

9.4.4.4.10 Changes to Birds from Collisions with Vehicles and Equipment

9.4.4.4.10.1 Potential Effects

Survival and Reproduction

A total of 700 vehicles per day have been modelled to be using the north-south (to the Northern Road Link Project Road) segment of the Project, and 100 vehicles per day have been modelled to be using the east-west segment (to Marten Falls First Nation). Most vehicular traffic on the north-south segment of the Project will be medium and heavy truck usage, consisting of 71 percent of traffic. Most traffic on the east-west section of the Project is expected to be light vehicle traffic (77 percent of all traffic) (**Appendix W**). The increase in Project-related traffic during Operations may increase the number of bird-vehicle collisions relative to existing conditions.

9.4.4.4.10.2 Mitigation and Enhancement Measures

Mitigation measures that will reduce potential bird-vehicle collisions during Operations are:

- Posting and enforcement of an 80 kilometre / hour speed limit during Operations; and
- As per the Ministry of Transportation's Brush Control Maintenance Quality Standard (MQS-324) and Grass Control Maintenance Quality Standard (MQS-326), mowing will be completed regularly to maintain vegetation at rest areas and within 185 metres of road signs and other objects that need to be seen (for example, guide rails) below 2 metres in height (Ministry of Transportation, 2003). The maintenance of low vegetation heights which will reduce chance of birds nesting in and crossing the Project right-of-way and rest areas.

Mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.4.10.3 Predicted Residual Effects

The implementation of mitigation is anticipated to limit Project-related changes to the survival and reproduction of birds from increased collision risk with vehicles and equipment. However, there is a predicted net effect from this interaction and, so, residual effects were carried forward into the residual effects characterization.

Effects from increased bird-vehicle collisions are predicted to be possible, irreversible (long term), continuous, and confined to the effects assessment Construction Disturbance Area. Effects from increased bird-vehicle collisions during operations are predicted to be possible, irreversible (long term), continuous, and confined to the effects

assessment Construction Disturbance Area. Effects from increased bird-vehicle collisions during Operations on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects.

9.4.4.4.11 Changes to Birds from Wildlife Attractants

9.4.4.4.11.1 Potential Effects

Survival and Reproduction

Some bird species may use permanent Project infrastructure (for example, bridges) as nesting habitat. The use of material stockpiles and infrastructure for nesting could result in inadvertent disturbance or destruction of bird nests by Project staff.

Raptors and other scavengers may be attracted to animals killed by collisions with vehicles (Forbes, 2009). Wildlife may also be attracted to roadside litter (Forbes, 2009). Attraction of carnivores and predatory birds (for example, ravens and gulls) to the Project during Operations can increase predation pressure on prey bird species and may cause local population declines for these species (Canadian Wildlife Service, 2007; Liebezeit et al., 2009).

9.4.4.4.11.2 Mitigation and Enhancement Measures

The mitigation measures established and refined using adaptive management during Project Construction should be maintained during Operations. The following mitigation will be implemented to deter birds from nesting on Project material stockpiles during Project Operations:

- The slopes of material stockpiles will be maintained at 70 degrees or less to deter bank swallow nesting;
- Hanging brightly coloured strips of fabric over slope faces to deter birds. These must be well secured and weighted at the bottom; and
- Placing geotextile, plastic covers, or tarping over slope faces or stockpiles to prevent access by birds. It is important to avoid using nets or other cover types that could entangle birds and cause potential injury or mortality.

If material stockpiles or Project infrastructure that may support nesting migratory birds need to be disturbed during the nesting season (April 28 to August 14; Environment and Climate Change Canada, 2023c), non-intrusive pre-clearing nest surveys will occur within seven days prior to maintenance activities beginning. If any areas are found to have birds

exhibiting breeding behaviour, these areas, including an activity disturbance buffer, will be flagged and protected from disturbance until the fledglings have left the nest.

During operation of the Project, inspections of the road and rest areas will occur two days of each week and, based on these inspections, debris and litter will be collected when detected (Ministry of Transportation, 2003). Additionally, as per the Ministry of Transportation's Debris Control Maintenance Quality Standard (MQS-331), debris less than 1 metres in diameter, including roadkill, will be removed within 48 hours; debris greater than 1 metres in diameter will be removed as detected (Ministry of Transportation, 2003). Generally, roadkill will be removed from the effects assessment Construction Disturbance Area and relocated to adjacent brush areas, as per the Waste and Excess Materials Management Environmental Protection (EP-9) requirements in the Ministry of Transportation's Maintenance Manual (Ministry of Transportation, 2003). As per the Waste and Excess Materials Management Environmental Protection requirements in the Maintenance Manual, depending on the location and weather at the time of roadkill removal, burial of small mammals occur in the roadside ditches, if this activity is permitted under a Certificate of Approval for Waste Management System (Ministry of Transportation, 2003).

Rest areas will be available every 50 kilometres along the road during Operations. The rest areas will be staggered every 25 kilometres, alternating on each side of the highway. These rest areas will contain waste receptacles. As per the Ministry of Transportation's Rest Area/Picnic Site Maintenance Best Practice (MBP-325), during the rest areas operating season (in other words, months during the year when temperatures remain above 0 degrees Celsius and closing no sooner than October 15), litter in waste receptacles will be removed from rest areas when waste receptacles are 75 percent full (Ministry of Transportation, 2003).

9.4.4.4.11.3 Predicted Residual Effects

Mitigation should limit wildlife attractants and attraction of birds and their predators to the Project. However, attraction to the Project could still occur. As such, this Project–environment interaction was predicted to have a net residual effect on bird populations and was carried forward into the residual effects characterization.

Effects are predicted to be possible, irreversible (long term) (for example, permanent aggregate piles and culverts), continuous, and confined to the effects assessment Construction Disturbance Area. Effects from wildlife attractants on the ability of the bird populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects.

9.4.4.4.12 Changes to Birds from Blasting and Flying Rock

9.4.4.4.12.1 Potential Effects

Explosives may be used at quarry sites to excavate materials to be used for maintenance of the Community Access Road. Blasting activities may produce fly rock that has the potential to strike birds in the vicinity and cause injury or death. The risk of mortality from being struck by fly rock would be greatest for birds who occupy territories that overlap blasting sites, or for birds that are flying over blasting sites when blasting occurs.

9.4.4.4.12.2 Mitigation and Enhancement Measures

Best management practices for blasting activities will include:

- Ontario Provincial Standard Specification – General Specification for the Use of Explosives (Ministry of Transportation, 2014);
- Ministry of Transportation Ontario Environmental Reference for Highway Design;
- Ontario Regulation 244/97 (*Aggregate Resources Act*);
- Ministry of Transportation Ontario Noise Protocol and Environmental Guide for Noise; and
- Department of Fisheries and Oceans Guidelines for the Use of Explosives in or Near Canadian Fisheries Waters.

The mitigation measures established and refined using adaptive management during Project Construction for Blasting should be maintained during Maintenance. An environmental monitoring program will be implemented during Maintenance and will include policies and actions for avoiding and minimizing the risks of blasting and blasting materials to wildlife. During Operations, quarry blasting will be suspended within 10 kilometres of known or potential High Use Areas during the migratory bird breeding window of April 28 to August 14 (Environment and Climate Change Canada, 2023c). If adherence to the timing windows and restrictions is not possible, the Owner / Operator will develop site-specific mitigation and monitoring in consultation with appropriate regulatory agencies. This may include implementation of a buffer zone survey around the perimeter of blasting activities and surrounding forested habitat, whereby blasting will be prohibited if raptor stick nests are observed within 500 metres from the blasting location.

9.4.4.4.12.3 Predicted Residual Effects

Due to the infrequent timing of blasting, and with the implementation of mitigation, blasting and fly rock from the Project during Operations is not expected to result in injury or mortality to birds. There is no net effect predicted for this Project–environment

interaction on bird survival and reproduction. Therefore, this interaction was not carried forward in the assessment.

9.4.4.4.13 Changes to Birds from Chemical or Hazardous Material Spills

9.4.4.4.13.1 Potential Effects

Survival and Reproduction

There is the potential for accidental spills of fuels and other materials from malfunctions of equipment or spills during equipment or vehicle refuelling during maintenance activities or through fuel and hazardous material releases from vehicle collisions. Effects from spills on water, soil, and vegetation quality, and subsequent effects on bird survival and reproduction, during Operations are the same as discussed in the Construction section, above.

9.4.4.4.13.2 Mitigation and Enhancement Measures

The mitigation measures established and refined using adaptive management during Project Construction should be maintained during operations. During Operations, mitigation measures will include a posting and enforcement of a speed limit on the highway, which should reduce potential for chemical or hazardous material spills by reducing vehicle collision risk. It is anticipated that commercial vehicles that are transporting dangerous goods on the Community Access Road should be adhering to the federal *Transportation of Dangerous Goods Act* and Ontario's *Dangerous Goods Transportation Act*.

A comprehensive list of mitigation measures to limit changes to surface water and groundwater quality from spills during operations is provided in the Surface Water Technical Support Document (**Appendix F**) and Groundwater Technical Support Document (**Appendix H**). Mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.4.4.13.3 Predicted Residual Effects

As discussed in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I**), Surface Water Technical Support Document (**Appendix F**) and Groundwater Technical Support Document (**Appendix H**), and Physiography, Terrain, and Soils Technical Support Document (**Appendix N**) there are predicted to be no residual effects from chemical or hazardous material spills on surface water quality, groundwater, soil, or vegetation quality during Operations. As such there was predicted to be no net effect on bird survival and reproduction, relative to existing conditions. Therefore, the potential effects of chemical or hazardous material spills were not carried forward in the assessment.

9.4.4.4.14 Changes to Individual Bird Species

Information on individual bird species assessed can be found in Birds Technical Support Document (**Appendix L**). The following bird species were assessed:

- Forest Birds: Red-eyed Vireo, Oven bird, Dark-eyed Junco
- Raptors: Osprey, Boreal Owl
- Shorebirds: Wilson's Snipe
- Waterfowl and Waterbirds: Mallard
- Bog / Fen Birds and Other Wetland Birds: Palm Warbler, Common Yellowthroat, Northern Waterthrush, Sora
- Species at Risk Birds: Canada Warbler, Evening Grosbeak, Chimney Swift, Bank Swallow, Barn Swallow, Common Nighthawk, Eastern Whip-poor-will, Eastern Wood-pewee, Olive-sided Flycatcher, Bald Eagle, Peregrine Falcon, Short-eared Owl, Black Tern, Lesser Yellowlegs, Rusty Blackbird, Yellow Rail

9.4.4.4.14.1 Potential Effects

Habitat Loss and Alteration

Although habitat will be initially removed during construction, the effects on habitat availability and survival and reproduction from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated). Temporary features that are decommissioned and reclaimed or naturally revegetate after Construction is complete are anticipated to provide functional habitat for bird species 5 to 10 years after the establishment of vegetation and would likely reduce the residual effects on bird survival and reproduction caused by the Project.

Sensory Disturbance

Habitat Availability

During Operations, even though traffic levels will vary throughout the day, traffic is expected to use the Community Access Road throughout the day and night and traffic can be present along the full length of the Community Access Road at any given time.

Distribution

During Operations, there are predicted to be a maximum of 700 vehicles per day for the north-south section and 100 vehicles per day for the east-west section of the Community Access Road (**Appendix W**). Although there may be intervals between vehicles passing along one location on the Community Access Road, vehicles may be

using the road through the day and night and there may not be a substantial interval without sensory disturbance.

Survival and Reproduction

During Operations, noise is predicted to reach 50 A-weighted decibels at 100 metres from the edge of the effects assessment Construction Disturbance Area (Final Acoustic and Vibration Environment Technical Support Document [**Appendix P**]). Sensory disturbance can occur along the entire length of the Community Access Road and can occur at any time of day during Operations.

Increase in Edge Habitat

Survival and Reproduction

Although the removal of habitat and creation of edge habitat will initially occur during construction, effects will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated). Temporary features that are decommissioned and reclaimed or naturally revegetate after Construction is complete are anticipated to provide functional habitat for bird within 60 to 80 years after the establishment of vegetation and would likely reduce the residual effects on bird species survival and reproduction caused by increased edge habitat created by the Project.

9.4.4.4.14.2 Mitigation and Enhancement Measures

Habitat Loss and Alteration

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources will be followed during Operations.

Sensory Disturbance

The following mitigation measures will be implemented to limit effects from sensory disturbance during Operations on birds:

- The migratory bird nesting season and timing of activities should be considered during operations;
- Complete maintenance work as quickly as possible to shorten the duration of disturbance;
- Posting and enforcement of speed limits to reduce vehicle speeds and associated noise and dust emission levels; and

- Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during operations.

Additionally, a Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed to achieve no net loss of bird habitat. Over the long term, measures undertaken as part of the Preliminary Biodiversity Offset Plan would be implemented to achieve a net increase in functional migratory bird habitat. However, because there is uncertainty in the effectiveness and timing of offset measures in the Preliminary Terrestrial Offset Biodiversity Plan, offsetting has not been considered in the conclusion of predicted residual effects below.

Increase in Edge Habitat

The effects assessment Construction Disturbance Area was designed to avoid removal of bird habitat and associated creation of edge habitat as much as practical, but a Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed to have no net loss of bird habitat.

Additional mitigation measures that will be implemented to limit effects from habitat loss and thereby effects from increased edge habitat on birds during Project Operations are discussed in **Section 9.4.4.4.14.**

9.4.4.4.14.3 Predicted Residual Effects

Habitat Loss and Alteration

Even after mitigation, potential bird habitat will be removed by the Project. Effects will occur in perpetuity (in other words, throughout Operations). The implementation of mitigation and enhancement measures is expected to limit negative effects. However, there are predicted net residual effects on bird habitat availability, distribution, and survival and reproduction during Operations.

Residual effects from habitat loss on the ability of bird population in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but low in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects. These predicted residual effects are applicable to Red-eyed Vireo, Ovenbird, Dark-eyed Junco, Osprey, Boreal Owl, Wilson’s Snipe, Mallard, Palm Warbler, Common Yellowthroat, Northern Waterthrush, Sora, Canada Warbler, Evening Grosbeak, Chimney Swift, Barn Swallow, Bank Swallow, Common Nighthawk, Eastern Whip-poor-will, Eastern Wood-Pewee, Olive-

sided Flycatcher, Bald Eagle, Peregrine Falcon, Short-eared Owl, Black Tern, Lesser Yellowlegs, Rusty Blackbird and Yellow Rail.

Sensory Disturbance

Even after implementation of mitigation, potential bird breeding habitat may be indirectly removed or degraded due to sensory disturbance during Operations of the Project. As such, there are predicted net residual effects on bird habitat availability, distribution, and survival and reproduction during Operations.

Residual effects from sensory disturbance on the ability of the bird population in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but low in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects. These predicted residual effects are applicable to Red-eyed Vireo, Ovenbird, Dark-eyed Junco, Osprey, Boreal Owl, Wilson's Snipe, Mallard, Palm Warbler, Common Yellowthroat, Northern Waterthrush, Sora, Canada Warbler, Evening Grosbeak, Chimney Swift, Barn Swallow, Bank Swallow, Common Nighthawk, Eastern Whip-poor-will, Eastern Wood-Pewee, Olive-sided Flycatcher, Bald Eagle, Peregrine Falcon, Short-eared Owl, Black Tern, Lesser Yellowlegs, Rusty Blackbird and Yellow Rail.

Increase in Edge Habitat

Increased predation risk will occur throughout the Operations Phase. The implementation of mitigation and enhancement measures is expected to limit negative effects but there is a predicted net residual effect on bird survival and reproduction.

Residual effects from increased edge habitat on the ability of the bird population in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but low in magnitude. As such, this Project–environment interaction is carried forward to cumulative effects. These predicted residual effects are applied to Red-eyed Vireo, Ovenbird, Palm Warbler, Northern Waterthrush, Common Nighthawk, Eastern Whip-poor-will and Short-eared Owl.

9.4.4.5 Summary of Residual Effects

Table 9.4-12 provides a summary of the potential effects for birds, mitigation measures, and residual effects. Detailed information is included in **Appendix L**.

Table 9.4-12: Summary of Residual Effects for Birds and Characterization

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
• **All Birds**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*. • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Introduction and spread of invasive plant species—can affect plant community composition, which can affect bird habitat availability and distribution	• A comprehensive list of mitigation measures to control invasive plant species during construction is provided in the Vegetation Technical Support Document (**Appendix J**) and Peatlands Technical Support Document (**Appendix I**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.	• Residual changes in bird habitat availability and distribution due to introduction and spread of invasive plant species.	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration / Reversibility: Short term / Reversable • Frequency: Infrequent • Likelihood: Possible • Significance: Not Significant • Uncertainty: Low • Direct / Indirect: Indirect
• **All Birds**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Introduction and spread of invasive plant species—can affect plant community composition, which can affect bird habitat availability and distribution	• A comprehensive list of mitigation measures to control invasive plant species during Operations is provided in the Vegetation Technical Support Document (**Appendix J**) and Peatlands Technical Support Document (**Appendix I**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during Operations.	• Residual changes in bird habitat availability and distribution due to introduction and spread of invasive plant species.	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration / Reversibility: Long term / Reversable • Frequency: Infrequent • Likelihood: Possible • Significance: Not Significant • Uncertainty: Low • Direct / Indirect: Indirect

9.4.5 Ungulates

9.4.5.1 Project-Environment Interactions

As a component of the effects assessment, the Project activities were reviewed to find potential environmental interactions. These interactions were then assessed for potential effect (**Table 9.4-13**).

Table 9.4-13: Project-Environment Interactions – Ungulates

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary access roads and trails • Temporary construction camps • Right-of-way clearing and grubbing • Pits and quarries • Temporary concrete batch plants • Drilling / blasting / aggregate production • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* Decommissioning of temporary camps, roads / trails and staging areas	• Boreal Caribou and Moose	• Habitat availability • Habitat distribution	• Introduction and spread of invasive plant species—Introduction of invasive plants from Project activities can affect plant community composition, which can affect ungulate habitat availability and distribution. • Emissions of criteria air contaminants—Deposition of criteria air contaminant emissions (for example potential acid inputs) may change soil quality and vegetation and affect ungulate habitat availability and distribution. • Fugitive dust emissions—Deposition of dust particulates may change soil and vegetation quality and affect ungulate habitat availability and distribution. • Erosion and sedimentation—Vegetation clearing, earth moving, pit and quarry development and other Project activities can result in the release of sediment, which may change the composition and function of vegetation communities and affect ungulate habitat availability and distribution. • Changes in surface water quantity—Alteration of surface water drainage patterns, flows and levels that can cause changes to soils and vegetation, which can affect ungulate habitat availability and distribution. • Changes in surface water quality—Changes in surface water quality from Project activities could adversely affect habitat availability and distribution. • Changes to groundwater—Alteration of groundwater drainage and infiltration patterns, flows, and levels that can cause changes to soils and vegetation, which can affect ungulate habitat availability and distribution.
• **Construction**	• Same as previous	• Boreal Caribou and Moose	• Survival and reproduction	• Wildlife attractants—Attraction of wildlife to the Project site (for example food waste, sewage, petroleum-based products, dust suppressants, explosive powder, site runoff ponds) may increase human-wildlife interactions and change predator-prey relationships, which can affect animal survival and reproduction. • Blasting and associated fly rock—May result in injury or mortality to wildlife. • Chemical or hazardous material stored on the Project site, or spills—(for example petroleum products, ammonium nitrate) on site or along access or haul roads can affect wildlife survival and reproduction. • Increased predator access—Increased access for predators (for example wolf and black bear) and prey may increase predation risk and decrease survival and reproduction for moose and caribou. • Increase in public access—Could affect ungulate survival and reproduction through legal and illegal hunting. • Collision with vehicles and equipment—Vehicle or heavy equipment use may cause injury or mortality to individual caribou and moose.
• **Construction**	• Same as previous	• Boreal Caribou and Moose	• Habitat availability • Habitat distribution • Survival and reproduction	• Habitat loss—The direct removal or alteration of soil and vegetation that may change habitat availability, use, and connectivity and influence ungulate abundance and distribution. • Habitat alteration—Alteration of final terrain and soil conditions, and / or plant species composition, could change the types of ecosystems that can be reclaimed on the landscape and adversely affect ungulate habitat availability and distribution, and survival and reproduction. • Sensory disturbance—(for example lights, smells, noise, human activity) can alter ungulate habitat availability, use and connectivity (movement and behaviour), which can lead to changes in abundance and distribution and adversely affect survival and reproduction. • Linear barriers—Roads and snowbanks on roads could decrease habitat connectivity and adversely affect ungulate distribution, which can lead to changes in abundance and distribution and adversely affect survival and reproduction.

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Operations**	• Operate the Community Access Road • Maintain the Community Access Road	• Boreal Caribou and Moose	• Habitat availability • Habitat distribution	• Introduction and spread of invasive plant species—Can affect plant community composition, which can affect ungulate habitat availability and distribution. • Emissions of criteria air contaminants—Deposition of criteria air contaminant emissions (for example potential acid inputs) may change soil quality and vegetation and affect ungulate habitat availability and distribution. • Fugitive dust emissions—Deposition of dust particulates may change soil and vegetation quality and affect ungulate habitat availability and distribution. • Erosion and sedimentation—Vegetation clearing, earth moving, pit and quarry development and other Project activities can result in the release of sediment, which may change the composition and function of vegetation communities and affect ungulate habitat availability and distribution. • Changes in surface water quantity—Alteration of drainage patterns and increased / decreased drainage flows, and surface water levels can cause changes to soils and vegetation, which can affect ungulate habitat availability. • Changes in surface water quality—Changes in surface water quality from Project activities could adversely affect habitat availability and distribution. • Changes to groundwater—Alteration of groundwater drainage and infiltration patterns, flows, and levels that can cause changes to soils and vegetation, which can affect ungulate habitat availability and distribution.
• **Operations**	• Operate the Community Access Road • Maintain the Community Access Road	• Boreal Caribou and Moose	• Survival and reproduction	• Wildlife attractants—Attraction of wildlife to the Project site (for example food waste, sewage, petroleum-based products, dust suppressants, explosive powder, site runoff ponds) may increase human-wildlife interactions and change predator-prey relationships, which can affect animal survival and reproduction. • Blasting and associated fly rock—May result in injury or mortality to wildlife. • Chemical or hazardous material stored on the Project site, or spills—(for example petroleum products, ammonium nitrate) on site or along access or haul roads can affect wildlife survival and reproduction. • Increased predator access—Increased access for predators (for example wolf and black bear) and prey may increase predation risk and decrease survival and reproduction for moose and caribou. • Increase in public access—Could affect ungulate survival and reproduction through legal and illegal hunting. • Collision with vehicles and equipment—Vehicle or heavy equipment use may cause injury or mortality to individual caribou and moose.
• **Operations**	• Operate the Community Access Road • Maintain the Community Access Road	• Boreal Caribou and Moose	• Habitat availability • Habitat distribution • Survival and reproduction	• Habitat loss—The direct removal or alteration of soil and vegetation that may change habitat availability, use, and connectivity and influence ungulate abundance and distribution. • Habitat alteration—Alteration of final terrain and soil conditions, and / or plant species composition, could change the types of ecosystems that can be reclaimed on the landscape and adversely affect ungulate habitat availability and distribution, and survival and reproduction. • Sensory disturbance—(for example lights, smells, noise, human activity) can alter ungulate habitat availability, use and connectivity (movement and behaviour), which can lead to changes in abundance and distribution and adversely affect survival and reproduction. • Linear barriers—Roads and snowbanks on roads could decrease habitat connectivity and adversely affect ungulate distribution, which can lead to changes in abundance and distribution and adversely affect survival and reproduction.

9.4.5.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following ungulates definitions apply to the effects assessment.

Ecological and Social Context

Context for ungulate valued components considers species sensitivity, resilience, adaptive capacity, current status and trends, and applicable legislation and best management practices. The current and future sensitivity and resilience of ungulate valued components to change caused by the Project are considered and includes Indigenous Knowledge, where available. Consideration of ecological context includes timing, such as when the effect could occur during a critical life cycle of the valued component. Context also informs whether the residual effect would alter the ability of the valued component ungulate populations to be self-sustaining and ecologically effective (in other words, the determination of significance). Ecological context is discussed in a reasoned narrative with other characteristics such as magnitude, geographic extent, duration, reversibility, and likelihood used to characterize residual effects and determine significance.

The Boreal population and Eastern Migratory population of caribou interact year-round and in winter, respectively, with the Ungulates effects assessment Local Study Area and Caribou effects assessment Regional Study Area. The four provincially delineated ranges that make up the caribou effects assessment Regional Study Area are Missisa, Nipigon, Ozhiski, and Pagwachuan, each of which are fully encompassed in the caribou effects assessment Regional Study Area.

The provincial status of Eastern Migratory caribou as Special Concern and lack of federal status on Schedule 1 of SARA means they are not given species or habitat protection, nor is there any provincial General Habitat Description or federal critical habitat defined for the species. Similar to boreal caribou, a major threat to Eastern migratory caribou is sensitivity to industrial disturbance and development, including road networks that are known to facilitate increased harvest because of improved access (Committee on the Status of Species at Risk in Ontario, 2017). Given their spatial overlap and shared habitat and food resources during winter, it is reasonable to assume that Eastern migratory caribou would experience the same predicted effects as boreal caribou when they occur in the Ungulate study areas and mitigation measures applied to boreal caribou would protect all “caribou”. As such, the boreal caribou ecotype was selected to act as a proxy for all caribou for the purposes of this assessment (and hereafter referred to as caribou, unless specifically noted).

Magnitude

Magnitude refers to the amount of change in an indicator relative to the existing conditions of a valued component and / or to known thresholds, standards, or guidelines. Magnitude is categorized as negligible, low, moderate, or high using numeric quantification or qualitative expression and supported by the literature through a reasoned narrative. Integrating ecological context to understand the point at which a given magnitude is large enough to be critical for a valued component is directly linked to the self-sustaining and ecologically effective status of the population, and therefore directly linked to significance.

9.4.5.3 Residual Effects – Construction Phase

9.4.5.3.1 Changes to Boreal Caribou and Moose from Introduction and Spread of Invasive Plant Species

9.4.5.3.1.1 Potential Effects

Habitat Availability and Distribution

The introduction and spread of invasive plant species have the potential to alter and degrade habitats relied upon by ungulates, particularly in areas with disturbed soil or located adjacent to the new disturbance (in other words, edge habitats). The introduction of invasive plant species into new areas can reduce the quality of ungulate habitats by altering species diversity and the community plant structure through competition with native species, and by changing soil conditions (for example, nutrients, moisture; Mack et al., 2000; Carlson and Shepherd, 2007). Land clearing during construction in the effects assessment Construction Disturbance Area will remove vegetation and disturb soils, increasing the potential for invasive plant species to establish and spread along the right-of-way and other areas of edge habitats in the ungulate effects assessment Local Study Area.

The regular transport of vehicles, equipment and personnel during the Construction of the Project could transport invasive plant seeds or plant parts into new areas inside and adjacent to the effects assessment Construction Disturbance Area.

9.4.5.3.1.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control invasive plant species. Herbicides (and pesticides) will not be used during construction. Environmental approval conditions, permits, or

authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

A list of mitigation measures to control invasive plants during construction is provided in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I).** Mitigation measures to limit the introduction and spread of invasive plants are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.1.3 Predicted Residual Effects

During construction, invasive species may occasionally be introduced within the effects assessment Construction Disturbance Area. Best management practices and the mitigation measures for controlling the spread of invasive species that will be implemented during construction are well understood and the methods have been demonstrated to be effective. However, introduction of invasive plants could still occur during construction, even following mitigation. As such, the Project is predicted to have a net residual effect on ungulate habitat availability and distribution from the potential introduction of invasive plants during construction and this interaction was carried forward to the residual effects characterization.

Should invasive plants be introduced from Construction vehicles, the plants will be contained and removed quickly resulting in a small, localized effect in the Construction Disturbance Area that is reversible in the short-term and therefore the effect is not predicted to reduce or degrade wildlife habitat. During construction, effects are possible and infrequent. Effects from the introduction of invasive plants on the ability of caribou and moose populations in the respective effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude.

9.4.5.3.2 Changes to Boreal Caribou and Moose from Emissions of Criteria Air Contaminants

9.4.5.3.2.1 Potential Effects

Habitat Availability and Distribution

The construction of the Project is expected to generate air particulate emissions, including carbon monoxide, sulphur oxides (including sulphur dioxide), nitrogen oxides, and other particulate matter. Activities during construction are expected to produce most

of the air emissions that would be attributable to the Project from the use of fossil fuels in construction vehicles, motorized equipment, machinery, power generators (to be used at temporary construction camps and temporary aggregate areas), the use of explosives (blasting), and the burning of non-hazardous waste materials (for example, food garbage at temporary construction camps). Indigenous communities including Fort Albany First Nation have shared concerns in relation to the emissions of criteria air contaminants, including how the Project might contribute to resource exploitation, leading to further air pollution and contamination for larger game such as moose and caribou (Firelight Research Inc., 2024).

The deposition of air particulate emissions can result in changes to soil and surface water quality, which has the potential to alter plant community structure, composition and diversity by modifying the pH, nutrient content and living organisms in the soil. Contamination of water, soil and vegetation quality from deposition of Project air emissions during construction has the potential to negatively affect ungulates if it reduces the quality of suitable forage and habitat in the ungulate effects assessment Local Study Area, which could ultimately affect the distribution of ungulate populations.

9.4.5.3.2.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

Potential mitigation measures outlined in the Ontario Ministry of Transportation Environmental Guide for Assessing and Mitigating the Air Quality Impacts and Greenhouse Gas Emissions for Provincial Transportation Projects (Ontario Ministry of Transportation, 2020) may be implemented, if feasible. A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during construction. Mitigation measures to limit emissions of criteria air contaminants are well understood, and the methods have been demonstrated to be effective.

Environmental approval conditions, permits, or authorizations issued for the Project construction, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

A comprehensive list of mitigation measures that will be implemented to limit air particulate emissions during construction is provided in the Atmospheric Environment Technical Support Document - Volume 1: Air Quality (**Appendix S**).

9.4.5.3.2.3 Predicted Residual Effects

As discussed in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I**), emissions of criteria air contaminants are anticipated to have negligible, possible effects on vegetation ecosystems, and, ultimately, ungulate habitat. As such, this interaction was determined to have no residual effects on ungulate habitat availability and distribution and is not carried forward in the assessment.

9.4.5.3.3 Changes to Boreal Caribou and Moose from Fugitive Dust Emissions

9.4.5.3.3.1 Potential Effects

Habitat Availability and Distribution

Fugitive dust emissions were a concern that was highlighted by Indigenous communities including Marten Falls First Nation and Weenusk First Nation (Marten Falls First Nation, 2023; MNP LPP, 2024b). Fugitive dust emissions are expected to be produced by the Project during construction activities such as land clearing, blasting, and infrastructure implementation (Atmospheric Environment Technical Support Document - Volume 1: Air Quality; **Appendix S**). Accumulation of airborne dust produced from the Project may result in local and direct changes to vegetation (Vegetation Technical Support Document [WSP, 2026b]). As a result, dust generated by the Project could adversely affect ungulates by degrading habitat quality and forage availability.

9.4.5.3.3.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

Dust deposition will be minimized during construction by following best industry practices and adhering to relevant government threshold values for deposition of acidifying compounds on specific plant species. Potential mitigation measures outlined in the Ontario Ministry of Transportation Environmental Guide for Assessing and Mitigating the Air Quality Impacts and Greenhouse Gas Emissions for Provincial Transportation Projects (Ontario Ministry of Transportation, 2020) may be implemented, if feasible.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during construction. A list of mitigation measures that will be implemented to limit dust deposition during construction is provided in the Atmospheric Environment Technical Support Document - Volume 1: Air Quality (**Appendix S**). Mitigation measures to limit dust deposition are well understood, and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.3.3 Predicted Residual Effects

Effects on caribou and moose habitat availability and distribution from fugitive dust emissions are predicted to be larger during operations than during construction because mitigations to limit dust emissions are predicted to be more effective during construction than during operations.

Dust deposition is predicted to result in negligible but certain changes to vegetation quality in the effects assessment Local Study Area (Vegetation Technical Support Document [**Appendix J**]; Peatlands Technical Support Document [**Appendix I**]). As such, there is a predicted net residual effect on caribou and moose habitat availability and distribution as a result of construction. The residual effects from fugitive dust emissions were carried forward into the residual effects assessment characterization.

Effects from dust emissions during construction are predicted to be certain, irreversible, continuous, and confined to the ungulate effects assessment Local Study Area. Effects from dust emissions on the ability of the ungulate populations in the caribou and moose effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude.

9.4.5.3.4 Changes to Boreal Caribou and Moose from Erosion and Sedimentation

9.4.5.3.4.1 Potential Effects

Habitat Availability and Distribution

Project Construction activities such as watercourse crossings, vegetation clearing, earth moving, pit and quarry development and other construction activities can result in exposure of vulnerable banks or slopes resulting in increased release of sediment. Sediment release into adjacent retained natural areas can have an effect on the composition and function of vegetation communities (Vegetation Technical Support Document [**Appendix J**]). These changes can reduce or degrade ungulate habitat

through localized changes in ecosystem composition, particularly wetland and riparian areas. The effects on vegetation would be expected to be localized and occur intermittently during construction but could include vegetation smothering and changes to drainage patterns and infiltration in the area of sediment deposits.

9.4.5.3.4.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

An environmental monitoring program will be developed and implemented during construction and will contain mitigation measures to control erosion and sedimentation. Erosion and sediment control measures will be developed and implemented in accordance with Ontario Provincial Standard Specifications for erosion and sediment control measures (Ministry of Transportation, 2021a, 2021c). Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

A list of mitigation measures that will be implemented during construction is provided in Vegetation Technical Support Document (**Appendix J**) and Surface Water Technical Support Document (**Appendix F**). These measures will be implemented to minimize effects from changes to erosion and sedimentation in the ungulate effects assessment Local Study Area during construction.

Mitigation measures to limit erosion and sedimentation are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.4.3 Predicted Residual Effects

Construction of the Project could result in localized increase in erosion-sedimentation processes at locations upstream or downstream of watercourse crossings and at receiving waterbodies. Environmental protection and monitoring plans developed for the Project Construction are expected to limit erosion and sedimentation. After implementing mitigation, the Project is not predicted to result in residual effects on the condition of peatland, upland, wetland and riparian ecosystems (in other words, ungulate habitat), relative to existing conditions (Vegetation Technical Support Document [WSP, 2026b]). As such, this interaction was not carried forward in the assessment.

9.4.5.3.5 Changes to Boreal Caribou and Moose from Changes in Surface Water Quantity

9.4.5.3.5.1 Potential Effects

Habitat Availability and Distribution

Project Construction activities such as constructing watercourse crossings, vegetation clearing, short-term water takings and discharge of construction water can cause changes to stream flows and / or water levels and erosion–sedimentation processes within or immediately upstream and downstream of the work area. Changes in the volume or rate of surface water flows during construction of the Project may adversely affect soils and peatland, wetland and riparian ecosystems through desiccation or inundation. Peatland, wetland and riparian ecosystems experience water level fluctuations as part of natural variability, and riparian ecosystems can recover relatively quickly from flooding.

Fluctuating surface water levels typically influence plant species composition, community structure, and species richness, and preventing changes in wetland water levels can cause a decrease in aquatic plant community diversity. Alternatively, changes in the amplitude, frequency, and timing of flood or drought compared to historical levels can cause adverse effects on wetlands, riparian areas and peatlands (Vegetation Technical Support Document [**Appendix J**]). These changes can reduce or degrade ungulate habitat through localized changes in ecosystem composition, particularly wetland and riparian areas.

9.4.5.3.5.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

Environmental approval conditions, permits, or authorizations issued for the Project will be followed, including those issued from Environment and Climate Change Canada, Fisheries and Oceans Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario.

A list of mitigation measures to limit changes to surface water quantity during construction is provided in the Surface Water Technical Support Document (**Appendix F**). This includes maintaining buffer zones of 30 metres around waterbodies. Mitigation measures to limit changes to surface water quantity are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.5.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**), Construction of the Project could result in small, localized changes to surface water quantity. After implementing mitigation, changes to surface water quantity are anticipated to be of negligible magnitude. As such, no net residual effects on caribou and moose habitat availability and distribution are predicted and this interaction was not carried forward in the assessment.

9.4.5.3.6 Changes to Boreal Caribou and Moose from Changes in Surface Water Quality

9.4.5.3.6.1 Potential Effects

Habitat Availability and Distribution

During construction, surface water may become contaminated if chemicals or substances (for example, petroleum products, sediments, and garbage) from Project equipment, vehicles, road surfaces, or blasting sites are transported into surface water during precipitation events (Surface Water Technical Support Document; **Appendix F**). This includes contamination of surface water from accidental spills and leaks of chemicals and hazardous materials and wash-off of organic debris during vegetation maintenance activities. Changes to surface water quality could have negative effects on ungulates by reducing habitat availability and distribution.

9.4.5.3.6.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

Mitigation measures during construction of the Project include adherence to federal and provincial regulations and guidelines regarding collection and storage of explosives and solid waste, such as the federal Explosives Act. Additionally, during the winter periods of Construction, sand will be used on the Community Access Road for de-icing instead of road salt, if required. Herbicides (and pesticides) will not be used during construction.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during construction. A list of mitigation measures to limit changes to surface water quality during construction is provided in the Surface Water Technical Support Document (**Appendix F**). Mitigation measures to limit changes to surface water quality are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will

be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.6.3 Predicted Residual Effects

As described in Surface Water Technical Support Document (**Appendix F**), the Construction of the Project is predicted to result in changes to surface water quality that are negligible in magnitude. As such, no net residual effects on ungulate habitat availability and distribution are predicted and this interaction is not carried forward into the assessment.

9.4.5.3.7 Changes to Boreal Caribou and Moose from Changes to Groundwater

9.4.5.3.7.1 Potential Effects

Habitat Availability and Distribution

Alteration of groundwater levels due to Project activities could have negative effects on caribou and moose habitat availability and distribution. Changes to vegetation communities are anticipated to be of moderate magnitude and probable to occur (Vegetation Technical Support Document [**Appendix J**]; Peatlands Technical Support Document [**Appendix I**]).

9.4.5.3.7.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during construction.

A list of mitigation measures to limit changes to groundwater quantity during construction is provided in the Groundwater Technical Support Document (**Appendix H**). The effectiveness of mitigation measures will be evaluated during construction and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.7.3 Predicted Residual Effects

With the implementation of mitigation measures, changes to groundwater regimes will be minimized and impacts on retained vegetation communities and ungulate habitat availability and distribution should be minimal. However, there are still anticipated to be measurable changes to vegetation due to change to groundwater quantity, which are

predicted to result in a residual effect on caribou and moose habitat availability and distribution. As such, this interaction is carried forward to the residual effects characterization.

Effects from changes to groundwater quantity are predicted to be probable, irreversible (long term), continuous, and confined to the effects assessment Local Study Area. Effects from changes to groundwater quantity on the ability of the caribou and moose populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude.

9.4.5.3.8 Changes to Boreal Caribou and Moose from Increase in Wildlife Attractants

9.4.5.3.8.1 Potential Effects

Survival and Reproduction

An increase in wildlife attractants during construction of the Project could have an adverse effect on the survival and reproduction of ungulate populations in the ungulate effects assessment Local Study Area.

In addition, ungulates may be attracted to areas within or near the effects assessment Construction Disturbance Area if certain resources become available during construction, such as de-icing salts. De-icing salts can provide a source of sodium for ungulates, and hotspots of moose-vehicle collisions have been found to occur near areas where de-icing salt ponds are present (Laliberté and St-Laurent, 2020; Rea et al., 2021). Indigenous Knowledge provided by Marten Falls First Nation included concerns related to the use of de-icing agents such as salt that may act as a moose and caribou attractant, resulting in increased potential for animal fatality due to vehicular collision and higher volume of hunters and poachers (Marten Falls First Nation, 2023).

9.4.5.3.8.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

Mitigations outlined will be implemented to minimize effects from increased wildlife attractants on caribou survival and reproduction in the ungulate effects assessment Local Study Area during construction.

An Environmental Protection Plan and Waste Management Plan will be developed and implemented that includes policies and actions anticipated to mitigate the attraction of wildlife to the effects assessment Construction Disturbance Area, particularly near the

temporary construction staging areas and temporary construction camps. During construction, the following mitigations will be implemented:

- The effects assessment Construction Disturbance Area will be kept clear of attractants such as food scraps and food containers to prevent attracting wildlife;
- Food wastes and oil products will be collected and temporarily stored in wildlife-proof containers. The containers will be transported offsite for recycling or disposed at a licensed disposal facility;
- Potentially toxic materials that attract wildlife will be stored in secure areas inaccessible to wildlife (for example, buildings, storage areas surrounded by wildlife-proof fencing), and toxic materials will be monitored continuously when removed from storage until they are used or returned to storage to prevent wildlife accessing and ingesting the materials;
- All personnel associated with the Project will be educated on the hazards of littering and feeding wildlife; and
- Littering and the feeding or harassment of wildlife will be prohibited by all Project personnel and is expected to reduce nuisance wildlife in and near the effects assessment Construction Disturbance Area.

The above mitigation measures will limit attraction to roads by carnivores to roadkill, which benefits ungulates by reducing attraction to the Project area during construction. In addition, de-icing salts will not be used during construction of the unpaved / gravel Community Access Road.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

Mitigation measures to wildlife attractants are well understood and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.8.3 Predicted Residual Effects

The implementation of mitigation measures described above, including effective waste management practices and avoidance of de-icing salt use, are expected to limit the attraction of ungulates and their predators to the effects assessment Construction Disturbance Area during construction. However, attraction to the Project could still

occur. As such, the Project is expected to result in a net residual effect on caribou and moose survival and reproduction. This interaction was carried forward into the residual effects characterization.

Effects are predicted to be possible, irreversible, continuous, and confined to the effects assessment Construction Disturbance Area. Effects from wildlife attractants and changes to predator-prey relationships on the ability of the ungulate populations in the caribou and moose effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude.

9.4.5.3.9 Changes to Boreal Caribou and Moose from Blasting and Associated Fly Rock

9.4.5.3.9.1 Potential Effects

Survival and Reproduction

During construction, explosives will be used at quarry sites to excavate materials for use during construction and to remove bedrock or large boulders in the right-of-way. Blasting activities may produce fly rock that has the potential to strike ungulates in the vicinity, and cause injury or death. The risk of mortality from being struck by fly rock would be greatest for ungulates who occupy home ranges that overlap quarry sites where blasting will occur. Blasting will be infrequent and will occur over short durations during construction. Given the high level of construction activity that would be occurring in the area prior to the blast, ungulates are expected to avoid the immediate area.

The potential effects on ungulates from the sensory disturbances associated with blasting during construction are addressed separately under Sensory Disturbance.

9.4.5.3.9.2 Mitigation and Enhancement Measures

Survival and Reproduction

The presence of operating equipment, people, noise, and lights during construction is expected to result in some avoidance of the effects assessment Construction Disturbance Area by ungulates. An Environmental Protection Plan and Blasting and Communication Management Plan will be developed and implemented that includes policies and actions for avoiding and minimizing the risks of blasting and blasting materials to wildlife (including moose and caribou). Industry best practices will be used for blasting activities, including adherence to:

- Ontario Provincial Standard Specification – General Specification for the Use of Explosives (Ministry of Transportation, 2014)

- Ministry of Transportation Ontario Environmental Reference for Highway Design
- Ontario Regulation 244/97 (*Aggregate Resources Act*)
- Ministry of Transportation Ontario Noise Protocol and Environmental Guide for Noise
- Department of Fisheries and Oceans Guidelines for the Use of Explosives in or Near Canadian Fisheries Waters

Blasting will be completed as quickly as possible to shorten the duration of disturbance. Open excavations and blasting areas will be fenced off if left unsupervised to avoid injury and mortality of wildlife. Quarry blasting and other construction activities will be suspended within 10 kilometres of known or potential High Use Areas for caribou during sensitive seasons (nursery areas: May 1 to July 14 very low tolerance, July 15 to September 15 low tolerance; winter use areas: December 1 to March 31; Ministry of Natural Resources, 2013a, 2013b). If adherence to the timing windows and restrictions is not possible, the owner / operator will develop site-specific mitigation and monitoring in consultation with appropriate regulatory agencies. This may include implementation of a buffer zone survey around the perimeter of blasting activities and surrounding forested habitat, whereby blasting will be prohibited if large mammals (in other words, moose and / or caribou) are observed within 500 metres from the blasting location.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

A list of mitigation measures that will be implemented during construction is provided in Acoustic and Vibration Technical Support Document (**Appendix P**). The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.9.3 Predicted Residual Effects

Due to the infrequent timing of blasting, and with the implementation of mitigation, blasting and fly rock from the Project during construction is not expected to result in injury or mortality of caribou or moose. There is no net effect predicted for this Project–environment interaction on ungulate survival and reproduction. Therefore, this interaction was not carried forward in the assessment.

9.4.5.3.10 Changes to Boreal Caribou and Moose from Chemical or Hazardous Material Spills

9.4.5.3.10.1 Potential Effects

Survival and Reproduction

Spills that occur in high enough concentrations can contaminate soils and affect aquatic organisms, soil organisms, vegetation, and wildlife, including ungulates. Direct exposure to the chemical through ingestion of contaminated water, soil or vegetation could result in acute or chronic illness or death. As a result, there is potential that Construction of the Project could cause chemical / hazardous material spills that could negatively affect the survival and reproduction of ungulate populations in the ungulate effects assessment Local Study Area.

9.4.5.3.10.2 Mitigation and Enhancement Measures

Survival and Reproduction

Mitigations during construction include adherence to federal and provincial regulations and guidelines regarding fuel and residue, chemical product, petroleum product, and hazardous substance collection and storage, use and handling, and disposal and treatment, such as the federal *Transportation of Dangerous Goods Act*, the Ontario Dangerous Goods Handling and Transportation Act, and the Ontario Environment Act. Additionally, an environmental monitoring program will be developed and implemented and will include policies and actions for limiting effects from spills on ungulate habitat.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.

A list of mitigation measures to limit changes to surface water and groundwater quality from spills during construction is provided in the Surface Water Technical Support Document (**Appendix F**) and the Groundwater Technical Support Document (**Appendix H**). Mitigation measures to limit chemical or hazardous material spills are well understood, and the methods have been demonstrated to be effective. The effectiveness of mitigation measures will be evaluated throughout Construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.10.3 Predicted Residual Effects

There are predicted to be no residual effects from chemical or hazardous material spills on surface water quality, groundwater, soil, or vegetation quality during construction. As such, there was predicted to be no net effect on ungulate survival and reproduction, relative to existing conditions. Therefore, the potential effects of chemical or hazardous material spills were not carried forward in the assessment.

9.4.5.3.11 Changes to Boreal Caribou from Habitat Loss and Alteration

9.4.5.3.11.1 Potential Effects

Habitat Availability

The Construction of the Project is expected to affect caribou habitat availability and quality in the Ungulate effects assessment Local Study Area and caribou effects assessment Regional Study Area.

Direct habitat loss would be contained within the effects assessment Construction Disturbance Area. A conservative assessment has been made by assuming that the entire effects assessment Construction Disturbance Area (4,700 hectares) is cleared of vegetation during construction.

Clearing of vegetation in the Construction Disturbance Area will directly affect the Albany River Provincial Park by removing 5.7 hectares in the Park. The other two provincial parks in the Ungulate Local Study Area (Little Current River and Ogoki River) will not be directly affected by vegetation removal in the Construction Disturbance Area (Section 7.3.1.1 of the Vegetation Technical Support Document [**Appendix J**]).

The effects assessment Construction Disturbance Area is predicted to permanently remove Category 1, 2, 3 functional habitat during construction, as follows (**Figure 9.4-7** to **Figure 9.4-9**):

- Category 1: Approximately 2,457 hectares of known and potential new Category 1 habitat will be removed (this includes 2,220 hectares of nursery areas, 1,182 hectares of winter use areas, and 643 hectares of travel corridors; areas that function as more than one Category 1 habitat type were not double counted). This represents approximately 52 percent of the effects assessment Construction Disturbance Area;
- Category 2: 1,611 hectares of known and potential new Category 2 seasonal range habitat will be removed. This represents approximately 34 percent of the effects assessment Construction Disturbance Area; and

- Category 3: 632 hectares of known and potential new Category 3 areas, including 8.8 hectares of water and 1.7 hectares of permanent disturbances, will be removed. This represents approximately 13 percent of the effects assessment Construction Disturbance Area.

Sensory disturbance associated with the Project construction activities is expected to also reduce the amount and quality of functional habitat if caribou avoid areas in proximity to the Project. This is considered indirect habitat loss and is accounted for by adding a 500 metre buffer to the effects assessment Construction Disturbance Area as per the approach with the federal recovery strategy (Environment and Climate Change Canada, 2020). The Construction Disturbance Area with a 500 metre buffer (in other words, direct and indirect habitat loss) encompasses an area of 31,717 hectares. Of that, 6,376 hectares overlaps existing anthropogenic disturbance.

The direct and indirect habitat loss associated with the Construction of the Project (Construction Disturbance Area + 500 metre buffer) is predicted to permanently remove Categories 1, 2, and 3 functional habitats **(Figure 9.4-7** to **Figure 9.4-9**):

- Category 1: 17,514 hectares of known and potential new Category 1 habitat will be removed (this includes 15,057 hectares of nursery areas, 10,769 hectares of winter use areas and 6,812 hectares of travel corridors; areas that function as more than one Category 1 habitat type were not double counted). This equates to approximately 55 percent of the spatial extent of the Construction Disturbance Area with a 500 metre buffer;
- Category 2: 9,317 hectares of known and potential Category 2 seasonal range habitat will be removed; and
- Category 3: 4,887 hectares of known and potential Category 3 areas, which includes 187 hectares of water, will be removed.

Habitat loss and alteration as a result of the Project Construction may affect caribou in a variety of ways, including the direct loss of important habitat areas that are necessary for biological functions (for example, Category 1 nursery areas) as well as potentially displacing caribou into less suitable habitats. These less suitable areas may have more competition for resources (between boreal caribou, eastern migratory caribou, and / or moose) and / or increased predation risk, which can subsequently have negative implications on survival and reproduction (Beyer et al., 2013; Beauchesne et al., 2014; Calizza et al., 2017; Rudolph et al., 2017; Mumma et al., 2018; Neufeld et al., 2021; Nagy-Reis et al., 2021).

Figure 9.4-8: Known and Potential New Caribou Category 1 Winter Use Areas in the Construction Disturbance Area + 500 metre buffer in the Residual Effects Assessment

CONFIDENTIAL

Figure 9.4-9: Potential New Caribou Category 1 Travel Corridors in the Construction Disturbance Area + 500 metre buffer in the Residual Effects Assessment

CONFIDENTIAL

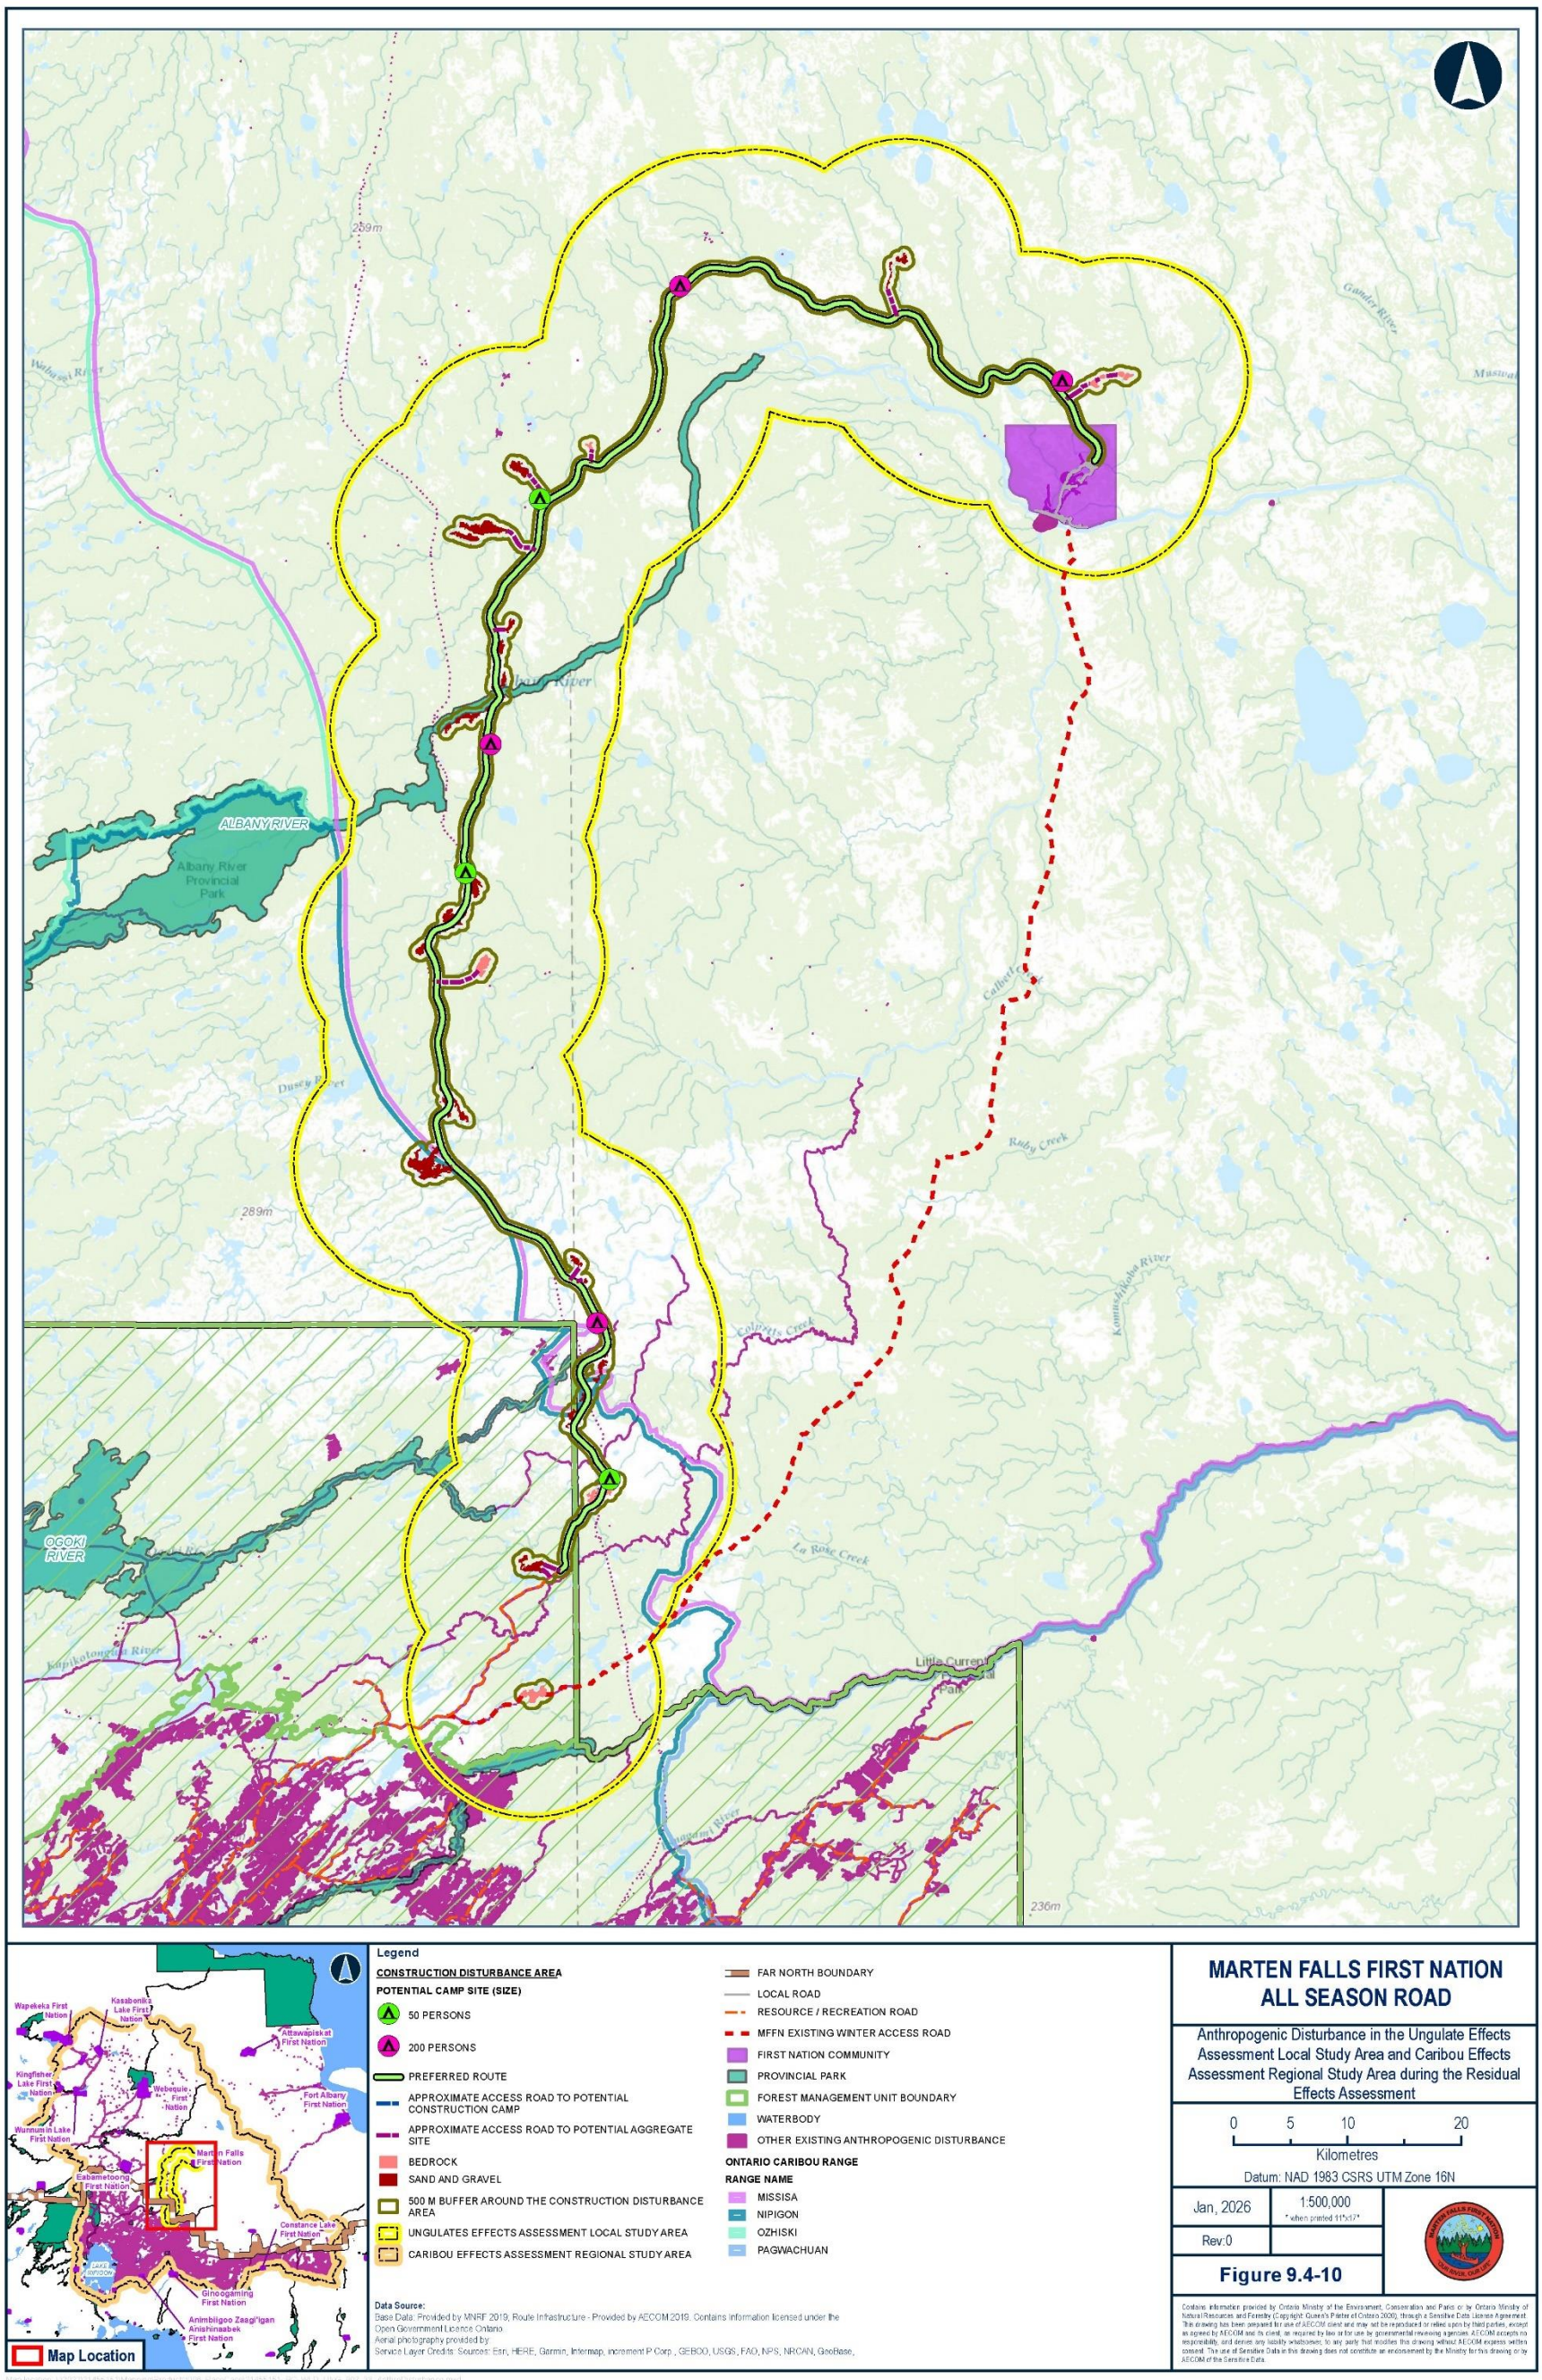
Local Study Area

The Project including a 500 metre buffer will add 25,342 hectares of permanent disturbance in the ungulate effects assessment Local Study Area (**Figure 9.4-10**). This is a conservative estimate because the Project footprint includes temporary features (for example, laydown areas) that may be reclaimed or revegetated following construction. The Project is expected to increase the proportion of total disturbance (anthropogenic and natural combined) in the ungulate effects assessment Local Study Area from 21.9 percent to 26.6 percent.

The amount of known and potential new Category 1 functional habitat that remains in the ungulate effects assessment Local Study Area with the addition of the Project (Construction Disturbance Area + 500 metre buffer) will be reduced compared to the existing conditions in the effects assessment area (**Figure 9.4-7** to **Figure 9.4-9**):

- Category 1 habitat in the ungulate effects assessment Local Study Area will be reduced by 6.7 percent. This includes a loss of:
  - 15,047 hectares of Category 1 nursery areas (-6.7 percent relative to the existing environment).
  - 10,769 hectares of Category 1 winter use areas (-6.2 percent relative to the existing environment).
  - 6,812 hectares of Category 1 travel corridors (-6.4 percent relative to the existing environment).
- Category 2 seasonal use areas in the ungulate effects assessment Local Study Area will be reduced by 6.3 percent; and
- Category 3 – remaining areas undisturbed in the ungulate effects assessment Local Study Area will be reduced by 9.9 percent.

Seasonal habitat quality in the ungulate effects assessment Local Study Area will be reduced with the addition of the Project by 5.7 percent to 6.7 percent relative to the existing environment. A summary of the combined loss of high and moderate quality habitat is as follows:



- 17,689 hectares of high and moderate quality calving habitat will be lost in the ungulate effects assessment Local Study Area as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of approximately –6.2 percent of high and moderate quality calving habitat in the ungulate effects assessment Local Study Area relative to the existing environment;

- 18,281 hectares of high and moderate quality summer habitat will be lost in the ungulate effects assessment Local Study Area as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of approximately –6.7 percent of high and moderate quality summer habitat in the ungulate effects assessment Local Study Area relative to the existing environment;
- 13,965 hectares of high and moderate quality fall habitat will be lost in the ungulate effects assessment Local Study Area as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of approximately –6.2 percent of high and moderate quality fall habitat in the ungulate effects assessment Local Study Area relative to the existing environment;
- 13,893 hectares of high and moderate quality winter habitat will be lost in the ungulate effects assessment Local Study Area as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of approximately –5.7 percent of high and moderate quality winter habitat in the ungulate effects assessment Local Study Area relative to the existing environment; and
- 15,295 hectares of high and moderate quality pre-calving habitat will be lost in the ungulate effects assessment Local Study Area as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of approximately -6.0 percent of high and moderate quality pre-calving habitat in the ungulate effects assessment Local Study Area relative to the existing environment.

Regional Study Area

The Project (including 500 metre buffer) will add 25,342 hectares of permanent disturbance in the caribou effects assessment Regional Study Area (**Figure 9.4-10**). This is a conservative estimate because the Project footprint includes temporary features (for example, laydown areas) that may be reclaimed or revegetated following construction. The Project is expected to increase the proportion of total disturbance (anthropogenic and natural combined) in the caribou effects assessment Regional Study Area from 24.3 percent to 24.4 percent. This remains below the 35 percent disturbance threshold identified in the federal recovery strategy for boreal Caribou as necessary to achieve and sustain self-sustaining populations (Environment and Climate Change Canada, 2020).

Figure 9.4-10: Anthropogenic Disturbance in the Ungulates Effects Assessment Local Study Area and Caribou Effects Assessment Regional Study Area during the Residual Effects Assessment

The amount of known and potential new Category 1 functional habitat that remains in the caribou effects assessment Regional Study Area with the addition of the Project will be reduced compared to the existing conditions in the effects assessment area (**Figure 9.4-11** to **Figure 9.4-13**):

- Category 1 habitat in the caribou effects assessment Regional Study Area will be reduced by 0.2 percent (17,514 hectares). This includes a decrease of 0.2 percent of nursery areas relative to the existing environment, 0.1 percent of winter use areas relative to existing environment, and 0.2 percent of travel corridors relative to the existing environment;
- Category 2 seasonal use areas in the caribou effects assessment Regional Study Area will be reduced by 0.2 percent; and
- Category 3 remaining areas undisturbed in the caribou effects assessment Regional Study Area will be reduced by 0.2 percent.

Seasonal habitat quality in the caribou effects assessment Regional Study Area will be reduced with the additional of the Project by 0.2 percent to 0.5 percent, relative to the existing environment.

Missisa Range

The disturbance in the caribou effects assessment Regional Study Area is confined to the Missisa and Nipigon ranges. The Construction of the Project (including 500 metre buffer) will add 21,413 hectares of new permanent disturbance in the Missisa range (**Figure 9.4-10**). This is a conservative estimate because the Project footprint includes temporary features (for example, laydown areas) that may be reclaimed or revegetate naturally following Construction.

The Project (with 500 metre buffer) is expected to increase the proportion of total disturbance (anthropogenic and natural combined) in the Missisa range, from 6.2 percent in existing conditions to 6.5 percent. This remains below the 35 percent disturbance threshold identified in the federal recovery strategy for boreal Caribou as necessary to achieve and sustain self-sustaining populations (Environment and Climate Change Canada, 2020).

The amount of known and potential new Category 1 functional habitat that remains in the Missisa range with the addition of the Project will be reduced compared to the existing conditions in the effects assessment area (**Figure 9.4-11** to **Figure 9.4-13**):

- Category 1 nursery areas in the Missisa range will be reduced by 0.4 percent (13,842 hectares);

Figure 9.4-11: Known and Potential New Caribou Category 1 Nursery Areas in the Caribou Effects Assessment Regional Study Area during the Residual Effects Assessment

CONFIDENTIAL

Figure 9.4-12: Known and Potential New Caribou Category 1 Winter Use Areas in the Caribou Effects Assessment Regional Study Area during the Residual Effects Assessment

CONFIDENTIAL

Figure 9.4-13: Potential New Caribou Category 1 Travel Corridors in the Caribou Effects Assessment Regional Study Area during the Residual Effects Assessment

CONFIDENTIAL

- Category 1 winter use areas in the Missisa range will be reduced by 0.2 percent (10,769 hectares);
- Category 1 travel corridors in the Missisa range will be reduced by 0.2 percent (6,812 hectares);
- Category 2 seasonal use areas in the Missisa range will be reduced by 0.6 percent (4,803 hectares); and
- Category 3 general use areas (not disturbed or water) in the Missisa range will be reduced by 1.9 percent (4,577 hectares).

Seasonal habitat quality in the Missisa range will be reduced with the addition of the Project relative to the existing environment**:**

- 16,645 hectares of high and moderate quality calving habitat will be lost in the Missisa range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.3 percent of high and moderate quality calving habitat in the Missisa range;
- 17,815 hectares of high and moderate quality summer habitat will be lost in the Missisa range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.4 percent of high and moderate quality summer habitat in the Missisa range;
- 13,921 hectares of high and moderate quality fall habitat will be lost in the Missisa range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.3 percent of high and moderate quality fall habitat in the Missisa range;
- 13,506 hectares of high and moderate quality winter habitat will be lost in the Missisa range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.3 percent of high and moderate quality winter habitat in the Missisa range; and
- 14,667 hectares of high and moderate quality pre-calving habitat will be lost in the Missisa range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.4 percent of high and moderate quality pre-calving habitat in the Missisa range.

Nipigon Range

The Construction of the Project (including 500 metre buffer) will add 3,929 hectares of new permanent disturbance in the Nipigon range (**Figure 9.4-10**). This is a conservative

estimate because the Project footprint includes temporary features (for example, laydown areas) that may be reclaimed following Construction.

At existing conditions, the proportion of anthropogenic and natural disturbance in the Nipigon range is 45.75 percent, which exceeds the 35 percent disturbance threshold identified in the federal recovery strategy for boreal caribou as necessary to achieve and sustain self-sustaining populations (Environment and Climate Change Canada, 2020). The addition of the Project (plus 500 metre buffer) is expected to increase the proportion of total disturbance in the Nipigon range by approximately 0.5 percent, to 45.83 percent.

The amount of known and potential new Category 1 functional habitat that remains in the Nipigon range with the addition of the Project will be reduced compared to the existing conditions in the effects assessment area (**Figure 9.4-11** to **Figure 9.4-13**):

- Category 1 nursery areas in the Nipigon range will be reduced by 0.1 percent (1,205 hectares);
- Category 1 winter use areas in the Nipigon range will not be reduced;
- Category 1 travel corridors in the Nipigon range will not be reduced;
- Category 2 seasonal use areas in the Nipigon range will be reduced by -0.4 percent (4,513 hectares); and
- Category 3 general use areas (not water or permanent disturbances) in the Nipigon range will be reduced by -0.01 percent (107 hectares).

Seasonal habitat quality in the Nipigon range will be reduced with the addition of the Project relative to existing conditions:

- 1,044 hectares of high and moderate quality calving habitat will be lost in the Nipigon range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.1 percent of high and moderate quality calving habitat in the Nipigon range;
- 466 hectares of high and moderate quality summer habitat will be lost in the Nipigon range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.1 percent of high and moderate quality summer habitat in the Nipigon range;
- 44 hectares of high and moderate quality fall habitat will be lost in the Nipigon range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.02 percent of high and moderate quality fall habitat in the Nipigon range;

- 387 hectares of high and moderate quality winter habitat will be lost in the Nipigon range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.08 percent of high and moderate quality winter habitat in the Nipigon range; and

628 hectares of high and moderate quality pre-calving habitat will be lost in the Nipigon range as a result of the addition of the effects assessment Construction Disturbance Area; this represents a change of -0.1 percent of high and moderate quality pre-calving habitat in the Nipigon range.

Habitat Distribution

Community members are concerned that the road will cut across migratory routes, affecting movement of animals, particularly moose and caribou (Marten Falls First Nation, 2023; Shared Value Solutions, 2024; Weenusk First Nation, 2023). Habitat alteration has the potential to make tracking and hunting caribou and moose species more challenging for Marten Falls First Nation members (Marten Falls First Nation, 2023; Weenusk First Nation, 2023). In addition, Marten Falls First Nation has expressed concerns related to health impacts on caribou species resulting in negative effects on animal size (Marten Falls First Nation, 2023).

Overall, the combination of direct habitat loss, indirect habitat loss, and fragmentation of suitable habitat from Construction of the Community Access Road are expected to result in a measurable change in habitat connectivity for caribou with home ranges that overlap the Project and ungulate effects assessment Local Study Area. However, in the caribou effects assessment Regional Study Area suitable habitats will remain largely connected. Changes that occur in the arrangement and connectivity of habitat will be permanent because the Project operations is indefinite; however, given animal movement and habitat use are dynamic over time, the magnitude of effect will likely vary during the lifespan of the Project.

The Construction of the Project's permanent and temporary linear features also has the potential to negatively affect caribou through increased human activity levels and sensory disturbance, increasing predation risk, hunter harvest pressure, and caribou-vehicle collisions.

Survival and Reproduction

During construction the Project is predicted to result in small changes in the distribution or connectivity of available undisturbed caribou habitat in the ungulate effects assessment Local Study Area and caribou effects assessment Regional Study Area relative to the level of direct and indirect disturbance under existing conditions. Changes

in habitat connectivity are more likely to affect caribou survival and reproduction if they impede access to high value areas such as nursery and winter use areas. The reproductive success of females and survival of calves are negatively affected if calving and post-calving habitats are unavailable, inadequate, or degraded (McCarthy et al., 2011; Environment and Climate Change Canada, 2020). As such, the loss of nursery areas and avoidance or reduced use of these areas due to proximity to disturbance, may influence local caribou survival and reproduction. This effect will be certain because the loss of high value habitat will be permanent. A reduction in local abundance is predicted to be continuous so long as individuals are displaced. Overall, habitat loss and alteration from Construction of the Project may displace a few individual caribou but is unlikely to have a demographic effect at the population level.

9.4.5.3.11.2 Mitigation and Enhancement Measures

Habitat Availability, Distribution and Survival and Reproduction

Mitigations outlined will be implemented during construction to limit effects from habitat loss and alteration on caribou habitat availability, distribution, and survival and reproduction as much as possible in the ungulate effects assessment Local Study Area and caribou effects assessment Regional Study Area (specifically in the Missisa and Nipigon ranges where habitat loss occurs). The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Avoidance of caribou sensitive and seasonally important habitat was considered in the assessment and selection of the Preferred Route. The Project footprint is designed to limit areas of vegetation clearing and soil disturbance to the extent feasible. Existing access roads will be used when available, and temporary activities will be concentrated spatially. Function, quality and connectivity of habitat features will be retained to the extent practical. Proper setbacks from known sensitive ecological features and key ungulate habitat features, including wetlands and mineral licks, will be used to the extent practicable; when sensitive ecological features are encountered and cannot be avoided, the applicable government agency will be engaged.

Construction of the Community Access Road will be conducted in phases to limit the amount of disturbance at any particular time and minimize barriers to movement. Elevation and slope of soil piles and berms will be minimized to allow ungulates to have clear line of sight to adjacent habitat. Along the right-of-way and access roads, gaps will be maintained in road berms and snowbanks to facilitate wildlife crossings at drainages, wildlife trails, strategic crossing points informed by movement data and Indigenous Knowledge, or connected habitat patches so that caribou movements across roads are not blocked. The Project construction schedule will avoid activities during the sensitive

timing windows for caribou (in other words, May 1 to September 15 for nursery areas, December 1 to March 31 for winter use areas) within 10 kilometres of known and potential new Category 1 areas, to the extent practical. When activity restrictions cannot be followed, the Ministry of the Environment, Conservation and Parks will be engaged to determine alternative approaches.

Construction practices will be utilized which encourage the eventual natural recovery and growth of native species (for example, minimize topsoil removal, preserve adequate substrate). When possible, work activities in wet areas will be scheduled during frozen conditions; under non-frozen conditions and where regulatory approvals allow, mats will be installed to limit effects on wetlands. Erosion control practices will encourage regrowth of vegetation. Inactive areas will likely be blocked with gates or physical control measures to prevent access. Marten Falls First Nation continues to engage in discussions with the Province regarding the ownership and future operations of the Community Access Road. Access and ownership including gating security / ID system, will require further dialogue between the communities and the Province.

Progressive restoration and revegetation will be implemented as non-permanent features will be decommissioned and restored or left to revegetate naturally. The time interval between commencement and completion of any work that disturbs earth surfaces will be a maximum of 20 calendar days. Commencement of such work will be considered to have occurred when the original stabilizing ground cover has been removed, including grubbing, or has been covered with fill material. Completion of such work will be considered to have occurred when the cover material (seed and mulch, seed and erosion control blanket, sod, rip-rap) has been applied. Where the timing of the operation results in a conflict with the application requirements of the specified cover, the owner / operator will determine appropriate interim measures that afford temporary protection until such a time as final cover can be applied.

Restored temporary use areas will be blocked to avoid re-entry and disturbance of revegetating areas through use of physical control measures (for example, rollback, removal of creek crossings). Restoration on site will consider maintaining or improving ungulate habitat, including planting native trees to accelerate revegetation. An Environmental Protection Plan and Cleanup and Reclamation Plan will be developed that includes practices for reclamation. Reclamation plans and practices will be confirmed through engagement with Indigenous communities.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction. Additionally, a Preliminary Biodiversity Offset Plan

was developed (**Appendix AB**) to achieve no net loss of caribou functional habitat. Over the long term, measures undertaken as part of the Biodiversity Offset Plan would be implemented to achieve a net increase in functional caribou habitat. However, because there is uncertainty in the effectiveness and timing of offset measures in the Biodiversity Offset Plan, offsetting has not been considered in the conclusion of predicted residual effects below.

In addition to the above, Marten Falls First Nation has proposed a number of mitigation measures relating to potential habitat loss and habitat alteration. The community has suggested mitigation measures, some of which can't be implemented in practice, but are acknowledged here as being recommended:

- The Project be built a 1-hour walking distance from mammal habitat;
- Consideration of the probation of logging or other resource exploitation activities around or near mammal habitat;
- Integration of wildlife crossings and wildlife signs along the Project corridor, particularly for moose and caribou;
- Adjusting the Project route away from sensitive areas;
- Preventing any dams from being built in conjunction with the construction of the Project; and
- Offering environmental monitoring training and environmental monitoring opportunities for Marten Falls First Nation members (Marten Falls First Nation, 2023).

9.4.5.3.11.3 Predicted Residual Effects

The implementation of mitigation measures described above are expected to limit negative effects from habitat loss and alteration on caribou in the caribou effects assessment Regional Study Area. Direct habitat loss will occur during construction and will be confined to the effects assessment Construction Disturbance Area; indirect habitat loss will also occur within a 500 metre buffer around the effects assessment Construction Disturbance Area.

After mitigation, the Project is expected to result in a net residual effect on caribou habitat availability and distribution and survival and reproduction from habitat loss and alteration during construction and operations. Therefore, this interaction was carried forward in the assessment.

Effects on habitat availability, distribution, and survival and reproduction of Boreal caribou from habitat loss and alteration during construction are predicted to be certain and permanent (irreversible) because most of the effects assessment Construction

Disturbance Area will remain disturbed indefinitely. The effects on caribou will be continuous and vary from the ungulate effects assessment Local Study Area to the caribou effects assessment Regional Study Area (for winter use and nursery areas) to beyond regional (for movement and connectivity). Some individuals that were collared in the ungulate effects assessment Local Study Area demonstrated seasonal travel east to the James Bay range and north to the Far North / eastern migratory range. The number of individuals in the population(s) who use these extended travel corridors, and the regularity of these long-distance movements, is uncertain.

Effects from habitat loss and alteration on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and of low magnitude for the Missisa range and moderate magnitude for the Nipigon range.

9.4.5.3.12 Changes to Boreal Caribou from Sensory Disturbance

9.4.5.3.12.1 Potential Effects

Habitat Loss and Distribution

Sensory disturbance during the Project construction could result in the indirect loss of suitable caribou habitat in the ungulate effects assessment Local Study Area if individuals avoid areas with sensory disturbance. Project activities are expected to produce loud noises, light spill, smells, and human activity that could cause caribou to avoid affected areas, potentially displacing them from suitable habitats for foraging, travel, rest, and refuge from predators. Noise during construction will be temporary, and some individuals may return when noise levels decrease.

During construction, sensory disturbance will mostly be confined to the active construction site(s) and will occur during the day for short durations spanning the start and end of the construction of each road segment. Unlike the construction of road segments, sensory disturbances at aggregate areas, quarry sites, access roads and construction camps are expected to occur over longer durations throughout Construction.

Construction activities, including construction and quarry blasting, are expected to produce ground vibration and an increase in air overpressure. As such, an increase in existing vibration levels is anticipated to occur on occasion, due to quarry and construction blasting activities, but blast-induced vibration is expected to be temporary in nature, occur only during specific activities, and limited to the vicinity of the effects assessment Construction Disturbance Area.

Survival and Reproduction

Sensory disturbance during the Construction of the Project may elicit negative effects on caribou induced through short-term behavioural and physiological responses, including startle response, elevated heart rate and increased production of glucocorticoids (in other words, steroid hormone produced in response to stress; Creel et al., 2002; Ewacha et al., 2017; Mirante et al., 2025). Changes in time spent feeding and running from sensory disturbances can decrease body condition, which can increase caribou vulnerability to predation. Loss of body weight in adult females due to interactions with zones of influence from anthropogenic developments also may result in reduced calf production.

Effects on survival and reproduction are predicted to be limited to the ungulate effects assessment Local Study Area and more likely to occur when the disturbance is in proximity to high use areas (in other words, Category 1 habitat).

9.4.5.3.12.2 Mitigation and Enhancement Measures

Mitigations outlined will be implemented to minimize effects from sensory disturbance on caribou habitat availability, distribution, and survival and reproduction in the ungulate effects assessment Local Study Area during construction. Additional mitigations to reduce effects from noise during construction is provided in Acoustic and Vibration Technical Support Document (**Appendix P**).

Avoidance of caribou sensitive and seasonally important habitat was considered in the assessment and selection of the Preferred Route. Proper setbacks from known sensitive ecological features and key ungulate habitat features, including wetlands and mineral licks, will be used to the extent practicable; when sensitive ecological features are encountered and cannot be avoided, the applicable government agency will be engaged.

Construction of the Community Access Road will be conducted in phases to limit the amount of disturbance at any particular time. Construction will be completed as quickly as possible to shorten the duration of disturbance. The Project construction schedule will avoid activities during the sensitive timing windows for caribou (in other words, May 1 to September 15 for nursery areas, December 1 to March 31 for winter use areas) within 10 kilometres of known and potential new Category 1 areas, to the extent practical. When activity restrictions cannot be followed, the Ministry of the Environment, Conservation and Parks will be engaged to determine alternative approaches.

An Environmental Protection Plan will be developed and implemented that includes measures to limit noise disturbance from construction activities; this includes prohibiting

use of engine retarder brakes, enforcing speed limits, reducing idling of vehicles, designing routes to minimize reversing (backup beeper), reducing traffic by locating camps near construction sites, and restricting construction traffic to designated areas and only construction personnel. Noise abatement, emission, and pollution control equipment on machinery will be in place, properly maintained and in good working order. Industry best practices will be used for blasting activities, including scheduling when in the vicinity of sensitive wildlife habitat areas. Forest buffers will be retained around quarries to reduce noise, where feasible. Aerial operations will be limited when possible; when not feasible, minimum ferry altitude of 400 metres above ground level will be maintained during sensitive timing periods to reduce sensory disturbance on caribou.

Light disturbance from nighttime operational activities will be limited by using directional lighting. Lighting required for Construction of the Project will be controlled, including direction (for example, focused on work areas and away from undisturbed areas) and timing (for example, minimize work at night) to minimize effects on caribou, while meeting operational health and safety requirements.

Vegetation will be established, as outlined on the required Rehabilitation Plan to align with the ‘Aggregate Resources of Ontario: Site Plan (2020) Standards. Reclaimed temporary use areas will be blocked to avoid re-entry and disturbance of revegetating areas through use of physical control measures (for example, rollback, removal of creek crossings). Restoration on site will consider maintaining or improving ungulate habitat, including planting native trees to accelerate revegetation. An Environmental Protection Plan and Cleanup and Reclamation Plan will be developed that includes practices for reclamation. Reclamation plans and practices will be confirmed through engagement with Indigenous communities.

9.4.5.3.12.3 Predicted Residual Effects

The implementation of mitigation measures is expected to limit negative effects from sensory disturbance in the ungulate effects assessment Local Study Area, but sensory disturbance is predicted to reduce the quality of caribou habitat by causing avoidance and increased movements away from the effects assessment Construction Disturbance Area. After mitigation, the Project is expected to result in a net residual effect on caribou habitat availability and distribution and survival and reproduction from sensory disturbance during construction and operations. Therefore, this interaction is carried forward in the assessment.

Effects on habitat availability, distribution and survival and reproduction of Boreal caribou from sensory disturbance during construction are predicted to be certain, irreversible, and

continuous. Effects will be confined to the ungulate effects assessment Local Study Area (for habitat availability and survival and reproduction) and extend to the caribou effects assessment Regional Study Area for habitat distribution (because of the effect on connectivity). Effects from sensory disturbance on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and low in magnitude.

9.4.5.3.13 Changes to Boreal Caribou from Linear Barriers

9.4.5.3.13.1 Potential Effects

Habitat Availability and Distribution

Construction of the Project may result in fragmentation of caribou habitat. Fragmentation of wildlife habitat can result when linear corridor developments are placed in contiguous habitats and results in smaller, spatially distinct habitat patches (Andrews, 1990; Bayne et al., 2005; Beauchesne et al., 2014; Crooks et al., 2017; Thompson et al., 2019).

Habitat fragmentation from the Construction of linear corridors for the Project may also impede or restrict access to seasonally important habitats because of real (in other words, physical) or perceived (in other words, sensory) risk associated with the linear barrier and reduce the likelihood of caribou crossing. Alterations in species movement patterns, or barrier effects, can result in reduced use of suitable habitat and loss of seasonal resources, which can have demographic effects (Dyer et al., 2001; Carthew et al., 2009; Dunne and Quinn, 2009; LeBlond et al., 2013; Muhly et al., 2015; Environment and Climate Change Canada, 2020; DeMars et al., 2021).

Caribou in the ungulate effects assessment Local Study Area and the northern part of the caribou effects assessment Regional Study Area (in other words, the part of the study areas in the Missisa and Ozhiski ranges) are essentially naïve to permanent road disturbances and may demonstrate strong avoidance behaviours during construction and the early stage of Operations, which could result in a barrier to movement across the landscape of these study areas (in other words, beyond regional-scale effect). The effect would be continuous during the life of the Project and is likely to occur (in other words, probable) as animals may adapt to vehicle traffic and associated noise in the longer term.

Survival and Reproduction

Changes in habitat connectivity during construction are more likely to have demographic effects on caribou survival and reproduction if a linear barrier impedes or delays animal movement to important seasonal habitat such as nursery and winter use areas (Wilson et al., 2016; Boulanger et al., 2024). These changes can also reduce a population's

ecological effectiveness by reducing gene flow and limiting their potential for “rescue effects”, which occur when individuals immigrate into a small population and rescue that population from local extinction (Brown and Kodrick Brown, 1977; den Boer, 1981; Stacey and Taper, 1992).

The post-calving to autumn / rut periods are critical periods for foraging when animals must achieve satisfactory body weight and condition to increase the chance of becoming pregnant and producing a calf the following spring (Bradshaw et al., 1998; Cook et al., 2021). Linear barriers to high-quality foraging habitat, in addition to food quality, accessibility on summer and winter ranges, and insect harassment, can influence the body condition of caribou and contribute to population decline (van Moorter et al., 2020). Caribou that deflect around a linear barrier may have increased energetic costs to arrive at their seasonal habitat area, which may reduce survival and successful calf rearing.

9.4.5.3.13.2 Mitigation and Enhancement Measures

The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Avoidance of caribou sensitive and seasonally important habitat was considered in the assessment and selection of the Preferred Route. The Project footprint is designed to limit areas of vegetation clearing and soil disturbance to the extent possible. Existing access roads will be used when available, and temporary activities will be concentrated spatially. At watercourse crossings that occur within Category 1 caribou habitat and are on the north-south segment of the Preferred Route, and at watercourse crossings that occur within Category 1 habitat and on the east-west segment of the Preferred Route modified bridge and bridge embankments will be designed to incorporate terrestrial pathways adjacent to the aquatic habitat and allow for ungulate passage, where feasible given land cover considerations. These design features include increasing the height of bridge to minimum 4 metres vertical clearance, using natural substrates on the bridge embankments and under the bridge, allow for an unobstructed line of sight on either side of the bridge, and clear and maintain the minimum width of right-of-way at bridge crossings. In other locations along the Community Access Road where frequent crossings of species at risk are anticipated (in other words, in caribou Category 1 habitat and moose high suitability habitats), reduced speed limits will be implemented and wildlife-friendly road embankments with gentle slopes (in other words, gradual incline) and smooth crush material will be constructed to encourage safe crossing. Specific sites will be informed by caribou collar data, habitat modelling and Indigenous Knowledge.

Construction of the Community Access Road will be conducted in phases to concentrate activities spatially and temporally to minimize fragmentation and barriers to movement across the landscape. Elevation and slope of soil piles and berms will be minimized to allow ungulates to have clear line of sight to adjacent habitat (Wolfe et al., 2000). Along the Project right-of-way and the access roads, gaps will be maintained in road berms and snowbanks to facilitate wildlife crossing at drainages, wildlife trails, strategic crossing points informed by movement data and Indigenous Knowledge, or connected habitat patches so that caribou movements across roads are not blocked. Snowbanks will be limited as much as possible and to a height of less than 1.6 metres to allow for ungulates to see across the road (Rescan 2011). Snow clearing along the access roads will incorporate road pull-outs at regular intervals to provide refuge for wildlife moving along the Community Access Road corridor. Posted construction traffic speeds will be determined by temporary access road conditions and at the discretion of the Owner / Operator.

Progressive reclamation and revegetation will be implemented as non-permanent features will be decommissioned and reclaimed or revegetated naturally. Ongoing use of inactive or reclaimed areas will be prevented through the use of physical control measures.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction and operations.

9.4.5.3.13.3 Predicted Residual Effects

The implementation of mitigation measures is expected to limit negative effects from linear barriers in the ungulate effects assessment Local Study Area and caribou effects assessment Regional Study Area. However, the addition of a new permanent road is predicted to result in alteration of caribou movement patterns and reduce the quality of caribou habitat by causing avoidance of the Construction Disturbance Area, particularly for caribou that move between the Missisa and Ozshiki ranges and Missisa and Nipigon ranges.

After mitigation, the Project is expected to result in a net residual effect on caribou habitat availability and distribution and survival and reproduction from linear barriers during construction. Therefore, this interaction was carried forward in the assessment.

Effects on habitat availability, distribution, and survival and reproduction of Boreal caribou from increased linear barriers during construction are predicted to be continuous and probable. Effects will be local for habitat availability and regional to

beyond regional for habitat distribution and survival and reproduction. During construction, effects will be long term and irreversible. Effects from linear barriers on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and high in magnitude.

9.4.5.3.14 Changes to Boreal Caribou from Increased Predator Access

9.4.5.3.14.1 Potential Effects

Survival and Reproduction

During construction, vehicle traffic and human presence associated with the Project are likely to result in avoidance of the area by ungulates and predators. Once constructed, the Community Access Road is expected to have a sufficient amount of vehicle traffic that wolves would likely not or infrequently use the road right-of-way for travel during operations. However, predators are more likely to travel along access roads that have been decommissioned following Construction and have limited human activity because they will be naturally revegetating and may attract moose and deer; animals that select early seral vegetation for browse (McLoughin et al., 2019; Kautz et al., 2021). As a result, the increase in linear features due to the Project Construction could improve predator mobility and increase encounter rates between predators and ungulates in the ungulate effects assessment Local Study Area (James and Stuart-Smith, 2000; Whittington et al., 2011). Predators may be attracted by the moose and deer, and their increased presence and improved mobility may lead to increased encounter rates and predation risk for caribou.

This relationship, referred to as disturbance-mediated apparent competition, has been identified as a limiting factor for boreal caribou populations where linear densities are high and net primary productivity sustains high prey biomass (DeMars and Boutin, 2018; DeMars et al., 2019; Fryxell et al., 2020). The southern portion of the ungulate effects assessment Local Study Area (in other words, the Nipigon range) and caribou effects assessment Regional Study Area (in other words, the Nipigon and Pagwachuan ranges) contain a higher density of linear features and moose density relative to the northern portion of the study areas. The increase in early seral vegetation may have a negative effect on caribou survival and reproduction if moose alter their distribution to take advantage of the new foraging opportunities on the revegetating temporary features and wolves subsequently also select these areas. The effect would be continuous during the period that early to mid-seral vegetation occupies temporary features and is anticipated to be probable (in other words, likely to occur).

In contrast, in regions with low net productivity and low density of moose, the disturbance-mediated apparent competition mechanism may be relaxed or not apply (Neufeld et al., 2021; Superbie et al., 2022). In the northern portions of the ungulate effects assessment Local Study Area (in other words, in the Missisa range) and the caribou effects assessment Regional Study Area (in other words, the Missisa and Ozhiski ranges), the increase in early seral habitat following Construction is less likely to increase moose and wolf density and have a measurable effect on caribou survival and reproduction.

9.4.5.3.14.2 Mitigation and Enhancement Measures

Mitigations outlined will be implemented to minimize effects from increased predator access on caribou survival and reproduction in the ungulate effects assessment Local Study Area during construction.

The Project footprint is designed to limit areas of vegetation clearing and soil disturbance to the extent possible. Existing access roads will be used when available, and temporary activities will be concentrated spatially. Temporary linear features will be designed to decrease predator efficiency, by retaining vegetation under 2 metres, minimizing the width of linear features, and including switch backs and bends in temporary road construction. In addition, best management practices will be implemented during construction to reduce predator mobility when it is safe to do so; for example, only removing snow from access roads when necessary.

During construction, the ongoing use of inactive areas by predators will be minimized through physical control measures such as rollback, removal of creek crossings, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access. Progressive reclamation and revegetation will be implemented as non-permanent features will be decommissioned and reclaimed or revegetated naturally.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction and operations. Additionally, a Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed to achieve no net loss of caribou habitat. Over the long term, measures undertaken as part of the Preliminary Biodiversity Offset Plan would be implemented to achieve a net increase in functional caribou habitat. However, because there is uncertainty in the effectiveness and timing of offset measures in the Preliminary Biodiversity Offset Plan, offsetting has not been considered in the conclusion of predicted residual effects.

The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.14.3 Predicted Residual Effects

Considering the potential increase in predator encounters will be restricted to Project roads and adjacent habitat, an increase in predation risk is predicted to be limited to caribou with home ranges that overlap the ungulate effects assessment Local Study Area. Most of the effect on the caribou population from increased predator access is predicted to occur within the ungulate effects assessment Local Study Area with little to no measurable change at the scale of the caribou effects assessment Regional Study Area.

After mitigation, the Project is expected to result in a net residual effect on caribou survival and reproduction from increased predator access during construction and operations. Therefore, this interaction was carried forward in the assessment.

Effects on reproduction and survival of Boreal caribou from increased predator access are predicted to be probable, continuous, and confined to the ungulate effects assessment Local Study Area. During construction, effects will be long term and irreversible Effects from increased predation on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude.

9.4.5.3.15 Changes to Boreal Caribou from Increase in Public Access

9.4.5.3.15.1 Potential Effects

Survival and Reproduction

Linear features facilitate human movement into areas that were previously less accessible. As such, the Construction of a new permanent road and access roads for the Project can adversely affect caribou in the long term because of increased mortality from hunting and illegal harvest.

Non-Indigenous hunting of caribou has not been permitted in Ontario since 1929 (Ontario Woodland Caribou Recovery Team, 2008). An increase in human presence due to improved access will not increase non-Indigenous harvest rates of caribou because government-regulated hunting restrictions for non-Indigenous hunters would be maintained for this species at risk. Nonetheless, increased access into the region from improved roads and increased knowledge of the region due to the influx of workers and owner / operator could result in illegal harvest and other interactions with humans

that could disturb caribou during construction. Traffic along the Project roads and increased human presence in the effects assessment Construction Disturbance Area may result in avoidance by caribou of the accessible parts of the ungulate effects assessment Local Study Area, which could decrease the potential effect of hunters if caribou alter their distribution to more remote areas. Several Indigenous communities that have provided feedback on caribou have noted concerns specific to how an increase in public access to the Local Study Area may impact caribou survival and reproduction, highlighting the potential for effects on connections to the land and abilities to practice and transmit cultural conditions (Dillon, 2024; MNP LPP, 2024; Shared Value Solutions, 2024).

9.4.5.3.15.2 Mitigation and Enhancement Measures

Mitigations outlined will be implemented to minimize effects from increased public access on caribou survival and reproduction in the ungulate effects assessment Local Study Area during construction. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Limiting public access to the effects assessment Construction Disturbance Area during construction will decrease risk of injury or mortality to caribou due to illegal hunting. Work areas will have gated site entrances and employees will be prohibited from hunting or carrying firearms in the effects assessment Construction Disturbance Area during construction.

An Environmental Protection Plan will be implemented that includes measures to control and / or restrict public use of access roads and the Construction Disturbance Area during construction. Measures may include gates / manned gates, signage, reduced road standard, and reduced speed limits. Marten Falls First Nation continues to engage in discussions with the Province regarding the ownership and future operations of the Community Access Road. Access and ownership including gating security / ID system, will require further dialogue between the communities and the Province. The Environmental Protection Plan will also outline measures to minimize wildlife-human interactions during construction, including an education program that details to staff, owner / operators, and visitors how to take all reasonable precautions to avoid wildlife conflicts, mandatory encounter and incident reporting, and signage identifying dangers of discharging firearms near industrial activity.

During construction, employees will be prohibited from personal use of motorized recreational vehicles. During construction, the ongoing use of inactive areas by the public will be minimized through physical control measures such as rollback, removal of

creek crossings, felling of timber across temporary access roads, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access. Progressive restoration and revegetation will be implemented as non-permanent features will be decommissioned and reclaimed or revegetated naturally. The time interval between commencement and completion of any work that disturbs earth surfaces will be a maximum of 20 calendar days. Commencement of such work will be considered to have occurred when the original stabilizing ground cover has been removed, including grubbing, or has been covered with fill material. Completion of such work will be considered to have occurred when the cover material (seed and mulch, seed and erosion control blanket, sod, rip-rap) has been applied. Where the timing of the operation results in a conflict with the application requirements of the specified cover, the owner / operator will determine appropriate interim measures that afford temporary protection until such a time as final cover can be applied.

9.4.5.3.15.3 Predicted Residual Effects

The Project is expected to result in a measurable change in public access in the ungulate effects assessment Local Study Area relative to the existing environment. The increase in people in the area during the Project lifespan could result in a minor increase in illegal harvesting of animals.

After mitigation, the Project is expected to result in a net residual effect on caribou survival and reproduction from increased public access during construction. Therefore, this interaction was carried forward in the assessment.

Effects from increases in public access are predicted to be unlikely during construction, irreversible, continuous, and confined to the ungulate effects assessment Local Study Area. Effects from increased hunting and poaching on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude during construction.

9.4.5.3.16 Changes to Boreal Caribou from Collisions with Vehicles and Equipment

9.4.5.3.16.1 Potential Effects

Survival and Reproduction

There are currently no all-season roads in the ungulate effects assessment Local Study Area, and the community's winter access road (which is east of the ungulate effects assessment Local Study Area and within the Missisa caribou range) has a short season of use. As such, ungulate-vehicle collisions in the ungulate effects assessment Local

Study Area are expected to increase during construction relative to existing conditions. During construction, the source of traffic will be heavy equipment and vehicles transporting workers. Traffic will be confined to the active Construction segment(s) and on the segment(s) where workers will be travelling to and from the active site. Construction-related traffic is also anticipated to increase on roads south of the Project and in nearby communities (for example, Nakina, Geraldton) because of increased employment opportunities and human activity in the area.

Construction traffic in the effects assessment Construction Disturbance Area may result in avoidance by caribou during construction. Caribou have been found to reduce their use of areas within 1.2 to 5 kilometres from roads in Quebec (Leblond et al., 2011, 2013; Fortin et al., 2013). Avoidance of traffic by caribou would decrease the potential for injury or mortality from vehicle collisions.

9.4.5.3.16.2 Mitigation and Enhancement Measures

Mitigations outlined will be implemented to minimize effects from collisions with vehicles and equipment on caribou survival and reproduction in the ungulate effects assessment Local Study Area during construction. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

Collision risk during construction will be minimized with implementation of the Environmental Protection Plan, which includes measures to minimize collisions between wildlife and vehicles during construction. Measures will include an education program that details to staff, owner / operators, and visitors how to take all reasonable precautions to avoid wildlife collisions. In addition, the Environmental Protection Plan will include measures such as:

- Giving wildlife the right-of-way;
- Signage in areas where wildlife are regularly observed;
- Radio communication between staff of wildlife presence in construction area;
- Coordinating worker transportation to site to reduce traffic volumes, where practicable;
- Confining vehicle traffic to approved right-of-way, workspace and access roads;
- Leaving gaps in road berms and snowbanks to allow for movement across the construction area;
- Restrictions on the use of motorized recreational vehicles by employees and owner / operators while working, including prohibition of personal snowmobiles, all-terrain vehicles and other motorized recreational vehicles, except for authorized purposes;

- Mandatory encounter and incident reporting; and
- Reduced and enforced speed limits.

Construction vehicles' speed on the Community Access Road and temporary access roads will be adjusted according to conditions (for example, wildlife in the area, weather conditions). Long-term monitoring at diamond mines in the Northwest Territories and Nunavut has shown that the frequency of accidental mine-related wildlife mortalities from vehicle collisions has been extremely low (Dominion Diamond, 2014).

Pre-construction surveys will be completed to identify possible wildlife habitat features along the right-of-way (for example, mineral licks) and potential crossing locations where collision risks would be highest; signage will be placed in these areas. De-icing salts will not be used on the unpaved Community Access Road during construction to minimize ungulate attraction to the roadside.

Along the Project right-of-way and the access roads, gaps will be maintained in road berms and snowbanks to facilitate wildlife crossing at drainages, wildlife trails, strategic crossing points informed by movement data and Indigenous Knowledge, or connected habitat patches so that ungulate movements across roads are not blocked. Snow clearing along the access roads will incorporate road pull-outs at regular intervals to provide refuge for wildlife moving along the Community Access Road corridor.

In the event of a mortality of a species at risk due to collisions with equipment or vehicles during construction, the owner / operator and / or operator should report the incident to SAROntario@ontario.ca and the Natural Heritage Information Centre at NHICRequests@ontario.ca.

9.4.5.3.16.3 Predicted Residual Effects

Implementation of mitigation is predicted to limit caribou (and other wildlife) mortality from collisions with vehicles and equipment during construction. Considering the potential increase in caribou-vehicle collisions will be restricted to Project roads, a decrease in survival and reproduction is predicted to be limited to caribou with home ranges that overlap the ungulate effects assessment Local Study Area. The increase in mortality of caribou from vehicle collisions is predicted to be additive relative to other mortality factors and have little to no to effect on population survival and reproduction (in other words, lambda) at the scale of the caribou effects assessment Regional Study Area. If monitoring indicates that vehicle-related mortality may be strongly influencing caribou populations, then additional mitigation measures would be evaluated and implemented.

After mitigation, the Project is expected to result in a net residual effect on caribou survival and reproduction from collisions with vehicles and equipment during construction. Therefore, this interaction was carried forward in the assessment.

Effects are predicted to be possible during construction, irreversible, continuous, and confined to the ungulate effects assessment Local Study Area. Effects from collisions with vehicles and equipment on the ability of the caribou populations in the caribou effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude during construction and low to moderate magnitude.

9.4.5.3.17 Changes to Moose from Habitat Loss and Habitat Alteration

9.4.5.3.17.1 Potential Effects

Habitat Availability

During construction, the Project is expected to affect the quantity and quality of moose habitat in the ungulate effects assessment Local Study Area and the moose effects assessment Regional Study Area, which has the potential to adversely affect moose habitat use, forage availability and predator evasion. Direct habitat loss will be contained within the effects assessment Construction Disturbance Area. A conservative assessment has been made by assuming that the entire effects assessment Construction Disturbance Area will be cleared of vegetation during construction.

The effects assessment Construction Disturbance Area overlaps 4,700 hectares of land that is assumed to be directly removed by the Project during construction (**Figure 9.4-14**). Existing suitable habitat for moose varies across the effects assessment Construction Disturbance Area, and is predicted to contain high (758 hectares), moderate (3,704 hectares), low (141 hectares), and poor (97 hectares) suitability winter moose habitat (**Figure 9.4-14**). After land clearing activities, the area is considered poor suitability moose habitat.

High suitability habitat is concentrated primarily in the southcentral portion of the effects assessment Construction Disturbance Area in the northern portion of Segment BE (between the sand and gravel aggregate area “SG-08” and Alternative North Camp 1) (**Figure 4-3; Figure 9.4-14b**). This large concentration of high suitability habitat is a regenerating forest that burned in 1995 (about 30-years old) and likely provides moose with abundant forage under existing conditions (for example, early successional vegetation, shrub cover and young tree growth for browsing). Moose occupancy models were developed from aerial survey moose observations in 2022 and 2023 and predicted a high probability of moose occupancy in this regenerating burned area (**Figure 9.4-15**).

Figure 9.4-14: Winter Habitat Suitability for Moose in the Construction Disturbance Area + 500 metre Buffer in the Residual Effects Assessment

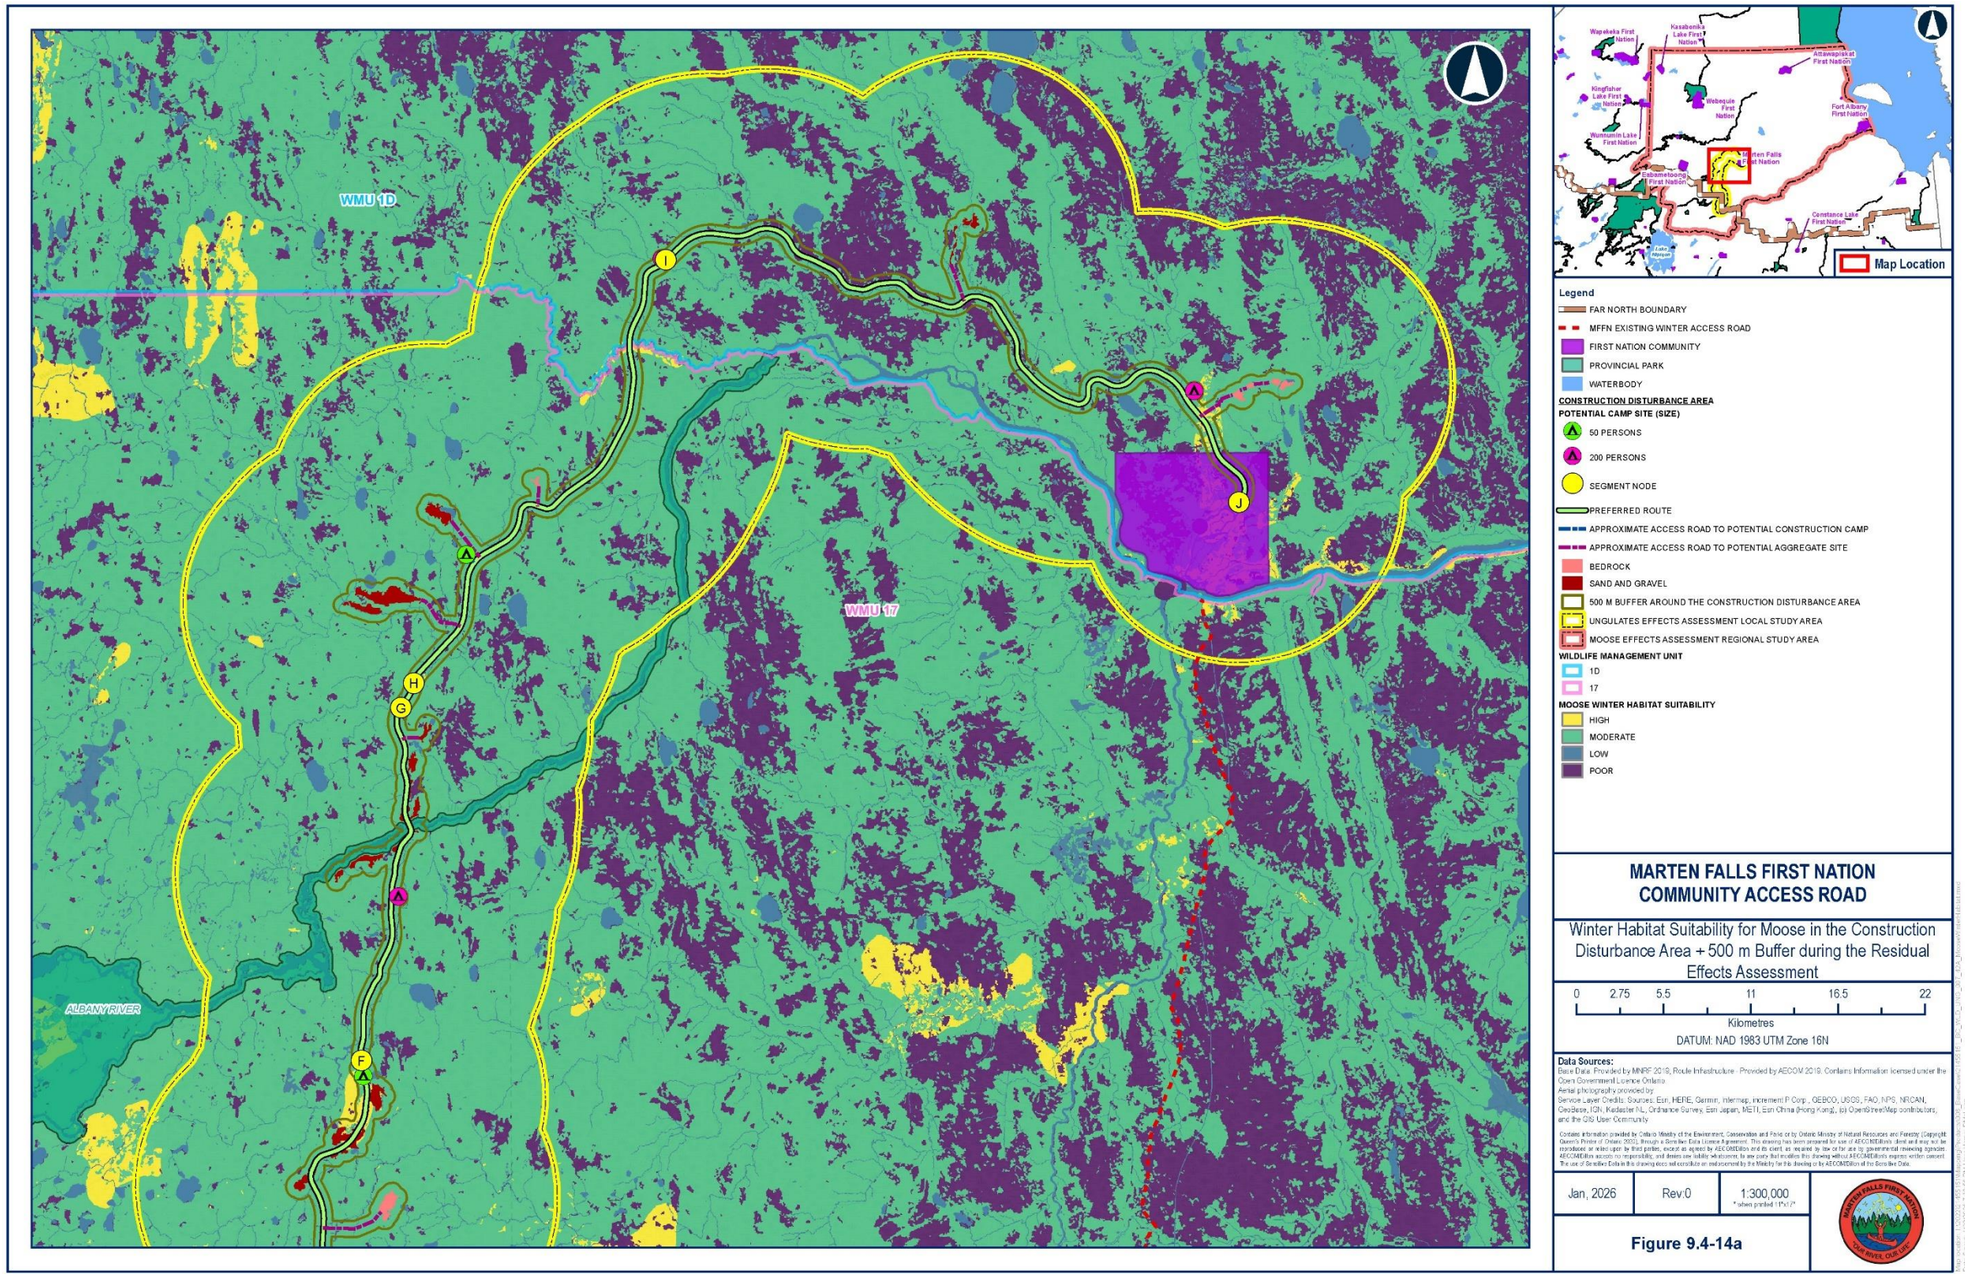


Figure 9.4-14b: Winter Habitat Suitability for Moose in the Construction Disturbance Area + 500 metre Buffer in the Residual Effects Assessment

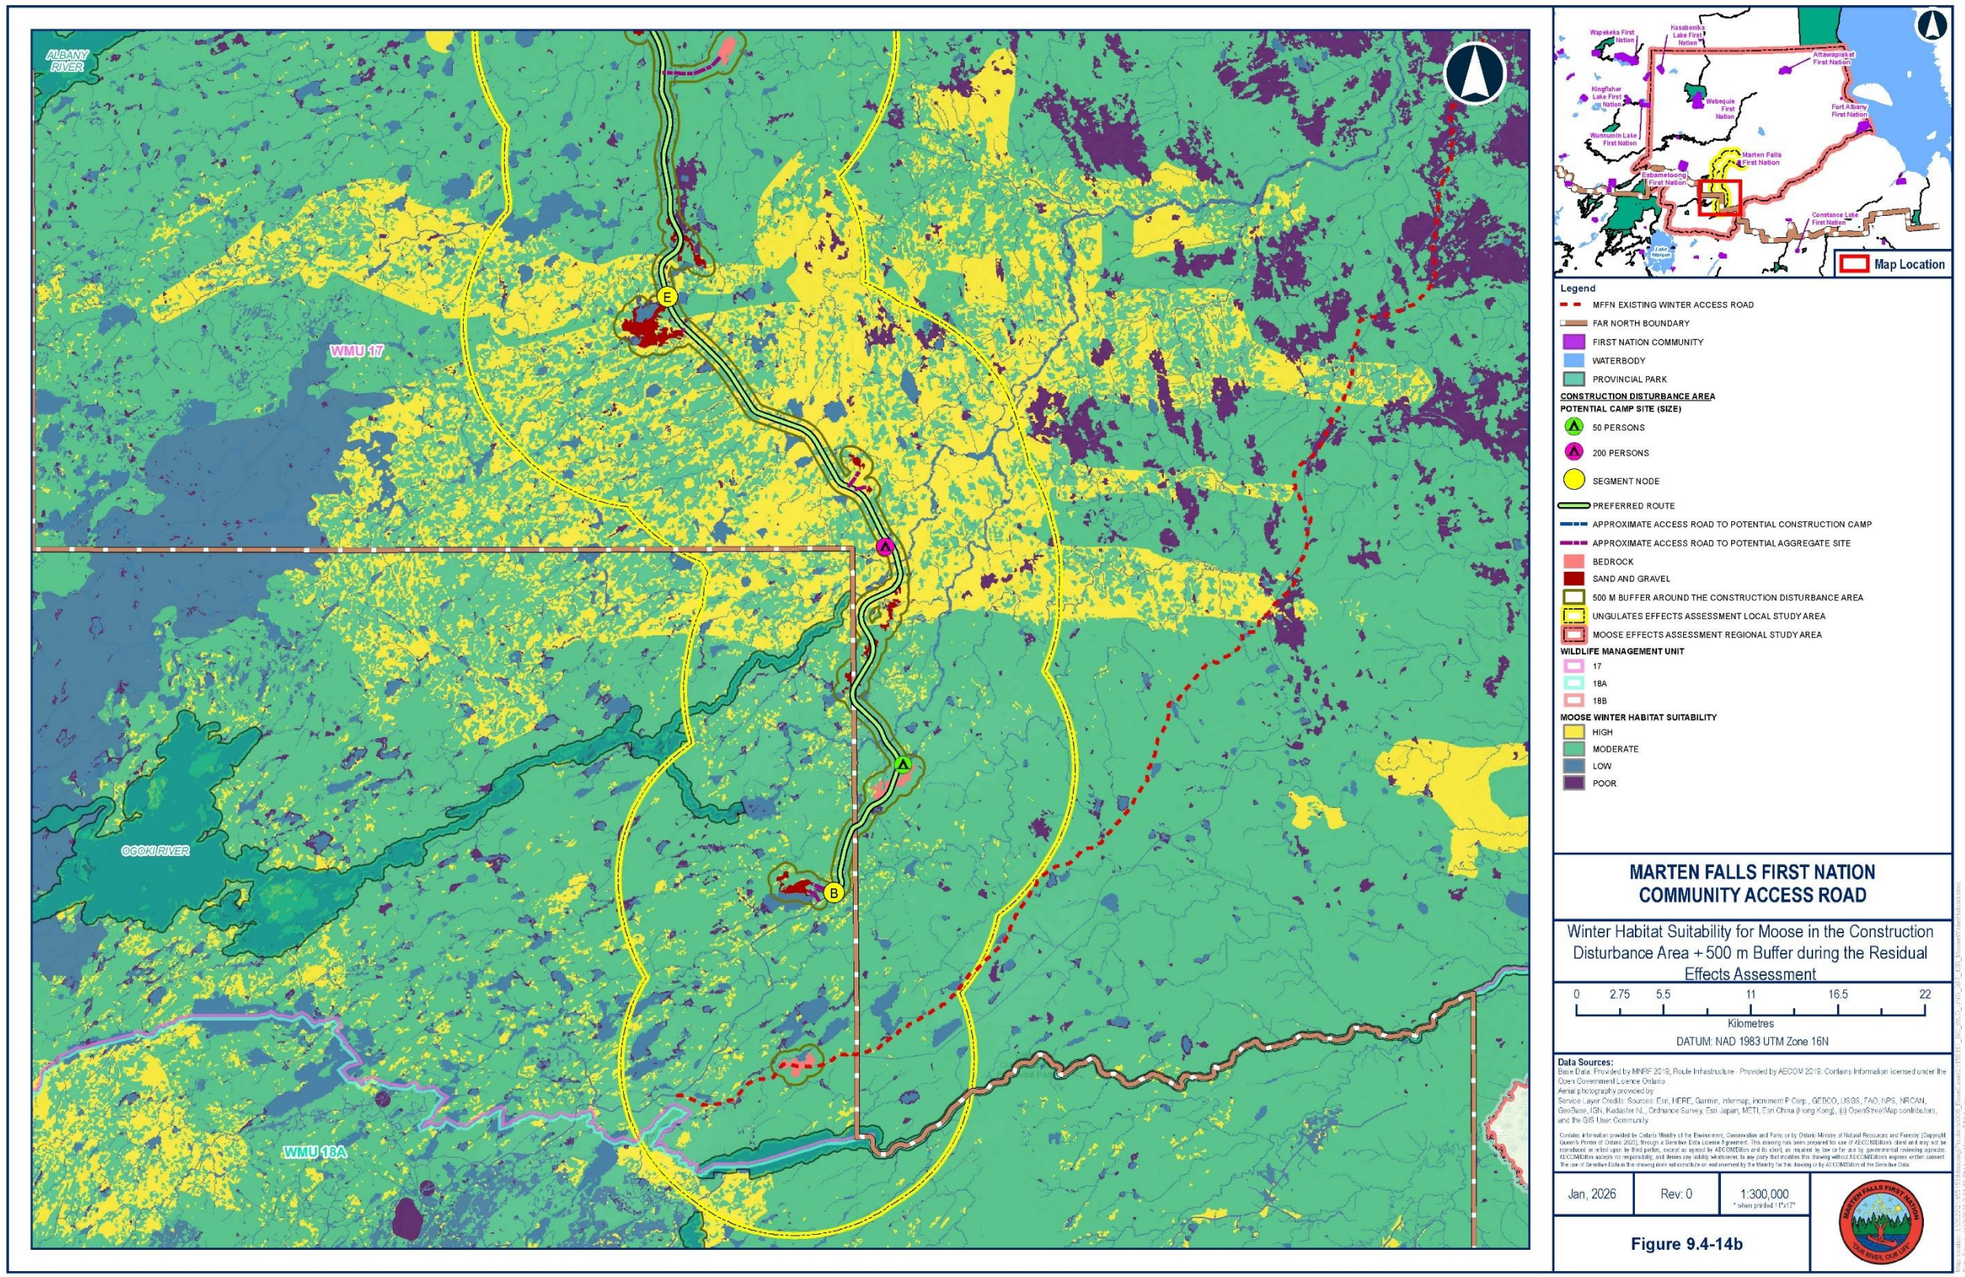

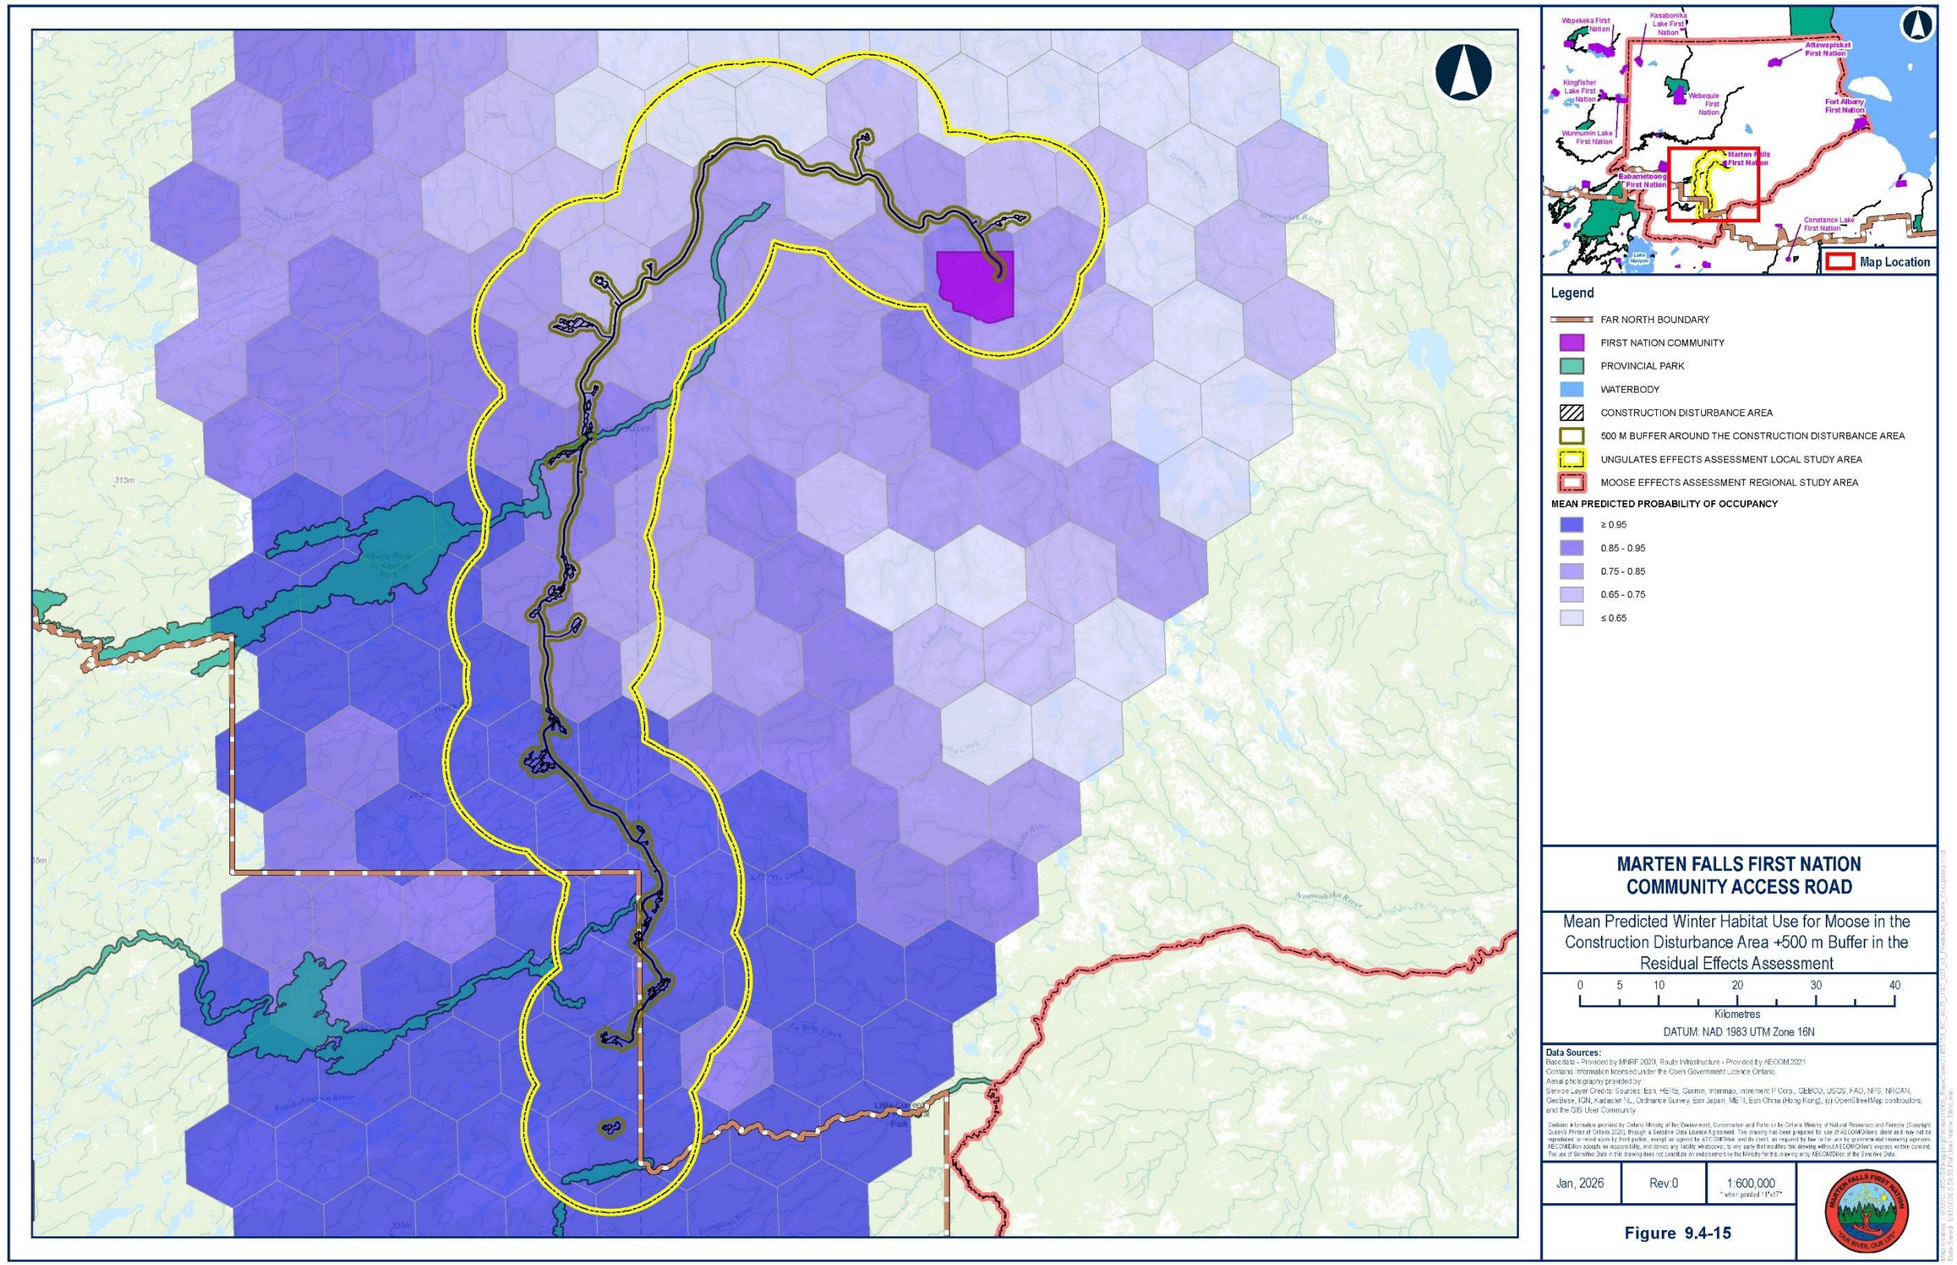

Figure 9.4-15: Mean Predicted Winter Habitat Use for Moose in the Construction Disturbance Area + 500 metre Buffer in the Residual Effects Assessment

This further suggests that the southcentral portions of the effects assessment Construction Disturbance Area and ungulate effects assessment Local Study Area provide highly suitable habitat for moose (**Figure 9.4-14b**)**.** Smaller extents of high suitability habitat occur within and adjacent to the easternmost portion of Segment IJ, the northern portion of Segment EF, and the Marten Falls First Nation (**Figure 9.4-14b**).

Moderate suitability moose habitat covers 79 percent of the effects assessment Construction Disturbance Area (**Figure 9.4-14**). It is dominated by landcover classes ≥ 40 years, including coniferous treed, coniferous swamp, mixed treed and treed fen. Low suitability habitat accounts for 3 percent of the effects assessment Construction Disturbance Area and includes herbaceous (≥ 40 years), sparse treed (≥ 40 years) and water landcover classes (**Figure 9.4-14**). Poor suitability habitat makes up the remaining 2 percent of the effects assessment Construction Disturbance Area (**Figure 9.4-14**). and consists of unfavourable winter habitat for moose, including open bog, open fen, and anthropogenic disturbance (Neilson and Boutin, 2017; Gillingham and Parker, 2008; McLoughlin et al., 2011).

Clearing of vegetation in the effects assessment Construction Disturbance Area will directly affect the Albany River Provincial Park by removing 5.7 hectares in the Park. The other two provincial parks in the Ungulate effects assessment Local Study Area (Little Current River and Ogoki River) will not be directly affected by vegetation removal in the Construction Disturbance Area (Section 7.3.1.1 of the Vegetation Technical Support Document [**Appendix J**]).

A total of 4,462 hectares of potential quality moose habitat in the ungulate effects assessment Local Study Area is expected to be directly removed during construction from land clearing activities. This represents a 1.2 percent and <0.1 percent decrease in potential quality moose habitat available in the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area, respectively, relative to existing conditions. Given the small proportion of potential quality moose habitat that will be directly removed during construction, available moose habitat is expected to remain abundant in the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area during construction.

Sensory disturbance (in other words, noise, smells, human presence) during construction has the potential to result in indirect loss of effective habitat of otherwise intact, suitable habitat for moose in the ungulate effects assessment Local Study Area if moose avoid areas with sensory disturbance. As the zone of avoidance or influence for moose due to sensory disturbance can vary and is not known for this area, habitat within a 500 metre buffer around the effects assessment Construction Disturbance Area was assumed to be affected by sensory disturbance. Using a precautionary approach to

avoid underestimating effects, within this 500 metre zone of influence, high and moderate suitability habitats were reduced to low suitability and low and poor suitability habitats were not changed (**Figure 9.4-14**). The 500 metre buffer contains 23,812 hectares of high and moderate suitability moose habitat that may be affected by sensory disturbance. If affected, this represents an additional 6.3 percent decrease in existing high and moderate suitability habitat in the ungulate effects assessment Local Study Area and 0.2 percent decrease in the moose effects assessment Regional Study Area.

Overall, direct and indirect (effective) habitat loss or alteration from the Project is expected to result in a decrease in available high and moderate suitability habitat, and an increase in low and poor suitability habitat during construction. Specifically, the Project is predicted to result in a 8.6 percent decrease in high suitability habitat and a 7.3 percent decrease in moderate suitability habitat in the ungulate effects assessment Local Study Area, and a small reduction (< 1.0 percent) in high and moderate suitability habitat at the Moose Regional Study. Low and poor suitability habitats are predicted to increase by 79.6 percent and 8.3 percent in the ungulate effects assessment Local Study Area, respectively, and by 1.0 percent and 0.2 percent in the moose effects assessment Regional Study Area, respectively. This assessment assumed that moose habitat loss (directly or indirectly) from land clearing, introducing Project infrastructure and sensory disturbance effects will remain unavailable in Construction (in other words, long-term effect).

The Project will directly remove about 1,607 hectares of wetlands during construction (bogs, fens, swamps, and fresh water marshes). This constitutes a loss of about 0.6 percent of existing wetlands in the ungulate effects assessment Local Study Area; therefore, wetlands are expected to remain abundant and available for moose in the ungulate effects assessment Local Study Area during construction.

Habitat Distribution

The Project is expected to affect moose habitat distribution and connectivity in the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area (in other words, local to regional scale effect) due to fragmentation of suitable moose habitat and incremental increases in anthropogenic disturbance. Most high and moderate suitability habitat in the ungulate effects assessment Local Study Area will remain intact and well connected in during construction, relative to existing conditions. However, the introduction of the Community Access Road will fragment (intersect) a large concentration of high suitability moose habitat in the southcentral portion of the ungulate effects assessment Local Study Area (**Figure 9.4-14**). Fragmentation from the Community Access Road could negatively affect moose, particularly individuals whose home ranges overlap this large area of high

suitability habitat, because it has the potential to reduce their ability to travel to suitable habitats located on opposite sides of the road. There is potential that the Community Access Road will disrupt or restrict moose movements when travelling across the ungulate effects assessment Local Study Area, especially in an east-west direction. During construction, the Project will also introduce 26.4 kilometres of access roads that extend from the Community Access Road to aggregate areas and construction camps; however, these access roads are less likely to have measurable effects on moose habitat connectivity.

The combination of direct habitat loss, indirect (effective) habitat loss or alteration (within the assumed 500 metre zone of influence), and fragmentation of suitable habitat from the Community Access Road, are expected to cause a measurable change in habitat connectivity for moose with home ranges that overlap the Project and ungulate effects assessment Local Study Area. In contrast, at the scale of the Moose effects assessment Regional Study Area, suitable moose habitats will remain largely intact and connected, and thus, the Project is predicted to have limited effects on habitat connectivity at the population level.

Survival and Reproduction

As described in Habitat Availability, Construction of the Project is predicted to directly remove 4,603 hectares of high, moderate and low suitability winter moose habitat (converting into poor suitability habitat), with the greatest loss of high suitability habitat expected in the southcentral portion of ungulate effects assessment Local Study Area (**Figure 9.4-14**). Moose in the region are expected to occupy home ranges varying from about 5.8 to 278 square kilometres (Vander Wal and Rodgers, 2012). The effects assessment Construction Disturbance Area is not expected to overlap the entire extent of individual moose home ranges, but instead is likely to remove available habitats within several moose home ranges in the ungulate effects assessment Local Study Area.

The majority of the effects assessment Construction Disturbance Area (84.5 percent) is located within Wildlife Management Unit 17, and the remaining northern segments are within Wildlife Management Unit 1D. As a result, moose with home ranges that overlap Wildlife Management Unit 17 are expected to be most affected by habitat loss and alteration due to the Project.

Vegetation clearing for the Project has the potential to effect moose by removing highly suitable habitats for moose that may function as important calving areas, foraging areas and / or refuge from predators. Habitat loss and alteration from the Project could displace individuals from highly suitable habitats into less favourable habitats. This

could lead to decreased forage availability through competition with other individuals and increased mortality risks from heightened predation and hunting pressures, ultimately affecting moose survival and reproduction.

Considering moose can occupy large home ranges (Vander Wal and Rodgers, 2012), and the Project will result in a relatively small direct and potential indirect loss or alteration of high and moderate suitability habitat (7.5 percent and 0.3 percent of the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area, respectively), habitat loss and alteration due to the Project is not expected to have a measurable effect on the survival and reproduction of moose at the population level of the moose effects assessment Regional Study Area.

9.4.5.3.17.2 Mitigation and Enhancement Measures

Mitigation measures outlined in **Section 9.4.5.3.11** will be implemented to avoid, minimize, and restore the effects from habitat loss and alteration on moose habitat availability, distribution, and survival and reproduction in the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area (specifically in Wildlife Management Unit 17 where a higher proportion of habitat loss and alteration will occur). Further, Marten Falls First Nation has proposed a number of mitigation measures to limit the effects on wildlife and their habitats from habitat loss and alteration, which are outlined in Marten Falls First Nation (2023).

The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.17.3 Predicted Residual Effects

A small amount of potential quality moose habitat that will be directly and indirectly lost or altered during construction, relative to the amount available in existing conditions. Specifically, the Project is predicted to directly remove 4,462 hectares of high and moderate suitability moose habitat that overlaps the effects assessment Construction Disturbance Area. This represents a 1.2 percent and <0.1 percent decrease in high and moderate habitat in the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area, respectively. Direct habitat loss is confined to the effects assessment Construction Disturbance Area. An additional 23,812 hectares of high and moderate suitability habitat is expected to be indirectly (effectively) lost or affected within the 500 metre buffer (zone of influence) around the effects assessment Construction Disturbance Area, which represents a potential 6.3 percent and 0.2 percent decrease in high and moderate suitability habitat in the ungulate effects

assessment Local Study Area and moose effects assessment Regional Study Area, respectively.

Overall, high and moderate suitability habitats are expected to decrease in availability by 7.5 percent in the ungulate effects assessment Local Study Area and 0.3 percent in the moose effects assessment Regional Study Area due to direct and indirect habitat loss or alteration associated with the Project. Therefore, a large proportion of suitable moose habitat is expected to remain undisturbed and connected in the ungulate effects assessment Local Study Area and the moose effects assessment Regional Study Area during construction.

The implementation of mitigation measures is expected to reduce negative effects from the Project on moose habitat availability, habitat distribution, and survival and reproduction; however, effects on moose from habitat loss and alteration cannot be avoided or mitigated entirely. Therefore, a net residual effect on moose is expected during construction from habitat loss and alteration. Residual effects from habitat loss and alteration were carried forward into characterization of residual effects.

Effects will be confined to the ungulate effects assessment Local Study Area (habitat availability, survival, and reproduction) and the moose effects assessment Regional Study Area (habitat connectivity and movement). Effects from direct habitat loss and alteration on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negative and low in magnitude.

9.4.5.3.18 Changes to Moose from Sensory Disturbance

9.4.5.3.18.1 Potential Effects

Habitat Availability and Distribution

Sensory disturbance (noise, smells, light spill, and human presence) produced by the Project could result in an indirect loss of effective moose habitat and habitat avoidance by moose in the ungulate effects assessment Local Study Area.

A 500 metre buffer around the effects assessment Construction Disturbance Area was precautionarily identified as the zone of influence where moose may exhibit avoidance behaviours and a loss of habitat effectiveness due to sensory disturbance. High and moderate suitability habitat within the 500 metre buffer includes a total of 23,812 hectares, which are conservatively assumed to decline in habitat effectiveness to low suitability habitat from exposure to Project-related sensory disturbance. This represents a 6.3 percent and 0.2 percent decrease in high and moderate suitability habitat in the

ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area, respectively.

The Project is expected to produce loud noises, light spill, smells, and increased human presence and activity. During construction, major sources of sensory disturbance include the use of heavy equipment and vehicles, blasting activities, and increased human presence in active construction areas and at temporary construction camps. Heavy equipment and vehicles will be used during construction, such as road construction, bridge and culvert installation, and drilling / blasting / aggregate production. The type and quantity of heavy equipment will vary with construction activity but would introduce a substantial and continuous amount of noise, smells, and human presence, which are expected to induce avoidance behaviours in moose in proximity to the effects assessment Construction Disturbance Area.

Blasting will occur in quarry sites and aggregate areas, and along portions of the Community Access Road that contain bedrock or boulders. Blasting will be infrequent during construction but is anticipated to increase noise and ground vibration levels relative to existing conditions (Acoustic and Vibration Technical Support Document [WSP, 2026a]), which could cause startle and fleeing behaviours in moose in proximity to the blast zone. Construction camps are expected to have increased human presence, noise, smells (for example, cooking), and light spill into adjacent areas. Sensory disturbance during construction will be restricted to day light hours and primarily confined to the Community Access Road segment under construction and vicinity.

Construction activities, including construction and quarry blasting, are expected to produce ground vibration and an increase in air overpressure. As such, an increase in existing vibration levels, is anticipated to occur on occasion, due to quarry and construction blasting activities, but blast-induced vibration is expected to be temporary in nature, occur only during specific activities, and limited to the vicinity of the effects assessment Construction Disturbance Area. Ground vibration modelling results indicate that quarry and construction blasting are predicted to induce vibrations of about 33.9 and 12.12 millimetres per second at 100 metres from the blast source, respectively (Acoustic and Vibration Technical Support Document [WSP, 2026a]**)**. Ground vibrations are expected to decrease with increasing distance from the blast source, with ground vibrations of 2.6 and 0.9 millimetres per second predicted at a 500 metres distance from a quarry blast and a construction blast, respectively (Acoustic and Vibration Technical Support Document [WSP, 2026a]).

Noise levels at about 90 A-weighted decibels are likely to have adverse effects on mammals, often resulting in avoidance from the source of the sound, as well as strong startle or freeze responses (Manci et al., 1988). Lower noise levels can still affect

wildlife by causing internal reactions that can be energetically costly, such as increased heart rate or heightened vigilance (Herrero et al., 2005). Although the predicted maximum noise levels from the Project do not reach or exceed 90 A-weighted decibels, the substantial increases in noise levels and occasional increase in vibration (from blasting) relative to existing conditions, are likely to affect moose by reducing the quality of moose habitat near construction activities and by inducing behavioural changes (in other words, habitat avoidance, startle responses).

Sensory disturbance effects associated with construction activities are expected to be felt continuously by moose with home ranges that overlap the ungulate effects assessment Local Study Area within 4 kilometres of the effects assessment Construction Disturbance Area (where changes to noise levels are constrained). These effects are likely to be stronger during construction.

Survival and Reproduction

Sensory disturbance, like noise, can lead to behavioural changes in moose (fleeing or startle response) or elicit physiological stress (for example, increased heart rate) that can be energetically costly (Manci et al., 1988; Herrero et al., 2005).

As a result, increases in moose movement away from human activity and / or physiological stress due to Construction-related sensory disturbance are unlikely to have a measurable effect on the overall energy budget of moose in the ungulate effects assessment Local Study Area and the moose effects assessment Regional Study Area (Neumann et al., 2011). As such, sensory disturbances expected to result from construction activities are not expected to measurably influence the moose population's survival and reproduction.

Similar to the effect on moose habitat availability and distribution, sensory disturbance effects on survival and reproduction would most likely be stronger during construction.

9.4.5.3.18.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from sensory disturbance on moose habitat availability and distribution and survival and reproduction in the ungulate effects assessment Local Study Area during construction.

The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.18.3 Predicted Residual Effects

The implementation of mitigation measures is expected to limit negative effects on moose habitat availability, habitat distribution, and survival and reproduction from sensory disturbance; however, effects on moose from sensory disturbance cannot be entirely avoided or mitigated. As such, sensory disturbances from construction activities and operation of the Community Access Road are predicted to reduce the suitability of moose habitat by causing avoidance and movements away from the effects assessment Construction Disturbance Area. Therefore, changes to moose habitat availability, habitat distribution, and survival and reproduction from sensory disturbance during construction are anticipated to have a net residual effect on moose. Residual effects from sensory disturbance were carried forward into the characterization of residual effects.

After implementation of mitigation measures, effects on moose from sensory disturbance during construction are expected to be long-term and irreversible (permanent), but there is potential for effects to span a shorter duration (in other words, short-term effect). Effects from sensory disturbance are probable and will be confined to the ungulate effects assessment Local Study Area (in other words, local scale effect). Effects will be continuous during construction. Effects from Project-related sensory disturbance on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negative and low in magnitude during construction.

9.4.5.3.19 Changes to Moose from Linear Barriers

9.4.5.3.19.1 Potential Effects

Habitat Availability and Distribution

Overall, the introduction of linear barriers has the potential to affect moose movement, reduce habitat connectivity and alter moose distributions within the moose effects assessment Regional Study Area during construction. Effects from linear barriers are likely to occur (in other words, probable) based on varied responses of moose to the type and activity levels of linear features.

Survival and Reproduction

As described above, Project linear features like the Community Access Road could function as a barrier to moose movement and result in changes to moose habitat availability and distribution during construction. This could affect moose survival and reproduction by influencing population distribution (Gagnon et al., 2007; Bowman et al., 2010; Wattles et al., 2018), and access to important habitats or resources (for example, quality forage, calving grounds, mineral licks). If moose movements are substantially

hindered, this could lead to reduced genetic transfer between moose with home ranges on either side of the Community Access Road (Wang and Schreiber, 2001; Bendeguz et al., 2020) in the moose effects assessment Regional Study Area (in other words, regional scale effect). However, it is unlikely that the Community Access Road will restrict moose movements enough to measurably reduce the survival and reproduction of moose at the regional population level within the moose effects assessment Regional Study Area.

9.4.5.3.19.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from linear barriers on moose habitat availability and distribution and survival and reproduction in the ungulate effects assessment Local Study Area during construction.

At watercourse crossings that occur within Category 1 caribou habitat and are on the north-south segment of the Preferred Route, and at watercourse crossings that occur within Category 1 habitat and on the east-west segment of the Preferred Route modified bridge and bridge embankments will be designed to incorporate terrestrial pathways adjacent to the aquatic habitat and allow for ungulate passage, where feasible given land cover considerations. These design features include increasing the height of bridge to minimum 4 metres vertical clearance, using natural substrates on the bridge embankments and under the bridge, allow for an unobstructed line of sight on either side of the bridge, and clear and maintain the minimum width of right-of-way at bridge crossings. In other locations along the Community Access Road where frequent crossings of species at risk are anticipated [in other words, in caribou Category 1 habitat (**Figure 9.4-7** to **Figure 9.4-9**) and moose high suitability habitats (**Figure 9.4-14**)], reduced speed limits will be implemented and wildlife-friendly road embankments with gentle slopes (in other words, gradual incline) and smooth crush material will be constructed to encourage safe crossing. Specific sites will be informed by caribou collar data, habitat modelling and Indigenous Knowledge. The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.19.3 Predicted Residual Effects

The implementation of mitigation measures is expected to limit negative effects on moose habitat availability, habitat distribution, and survival and reproduction from introducing linear barriers in the ungulate effects assessment Local Study Area during construction. However, the addition of the permanent, Community Access Road is expected to affect moose movements and behaviour (in other words, inducing avoidant behaviour) within and surrounding the ungulate effects assessment Local Study Area (in other words, local to regional scale effect). Reduced moose mobility and habitat

connectivity is expected to be most affected within the southcentral portion of the ungulate effects assessment Local Study Area where a large extent of high suitability habitat will be fragmented (**Figure 9.4-14b**).

As such, changes to moose habitat availability, habitat distribution, and survival and reproduction from linear barriers during construction are anticipated to have a net residual effect and is carried forward to the residual effects characterization.

During construction, effects from linear barriers are probable and continuous. Effects on moose habitat availability and survival and reproduction are expected to be felt by moose with home ranges that overlap the ungulate effects assessment Local Study Area (local effect) but also may affect the movement and connectivity of animals in the surrounding habitats of the moose effects assessment Regional Study Area (regional effect). Effects from linear barriers on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negative and low in magnitude during construction.

9.4.5.3.20 Changes to Moose from Increase in Predator Access

9.4.5.3.20.1 Potential Effects

Survival and Reproduction

The Project is predicted to slightly increase linear feature density by 0.05 kilometres per square kilometre in the ungulate effects assessment Local Study Area and <0.01 kilometres per square kilometre in the moose effects assessment Regional Study Area. This includes introducing access roads and the Community Access Road, which could improve predator mobility and provide access to areas that may have been more difficult to access. Predators may rely on these linear features for travel particularly in the winter (except hibernating black bears) when the presence of deep snow in non-cleared areas makes travel more energetically costly (Gurarie et al., 2011; Dickie et al., 2020).

Wolves and black bears prefer to travel on secondary roads with limited human activity and often avoid primary roads with greater traffic volumes (Dickie et al., 2017; Kunkel and Pletscher, 2000; Whittington et al., 2005). Given this, it is expected that during construction, predators in the ungulate effects assessment Local Study Area would largely avoid the Community Access Road and secondary access roads due to the sensory disturbances, vehicle traffic, and human presence associated with construction activities along these roads. As such, predation risk (from increased predator access) is not expected to measurably increase for moose in the ungulate effects assessment Local Study Area during construction.

9.4.5.3.20.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from increased predator access on moose survival and reproduction in the ungulate effects assessment Local Study Area during construction.

The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.20.3 Predicted Residual Effects

Implementing mitigation measures is expected to reduce the negative effects on moose survival and reproduction from an increase in predator access (from introduced Project linear features). However, it is uncertain how frequently predators will use access roads and the level of increase in encounter rates that will result (effect is likely but uncertain).

Considering that potential increases in predator encounters will be restricted to Project roads and adjacent habitats, effects from an increase in predator access due to the Project will be largely constrained to the ungulate effects assessment Local Study Area. Therefore, an increase in predation risk is expected to primarily affect moose with home ranges that overlap the ungulate effects assessment Local Study Area, with little to no measurable change to the moose population at the scale of the moose effects assessment Regional Study Area. Changes to moose survival and reproduction from increased predator access due to the Project are anticipated to have a net residual effect and is carried forward to the residual effects characterization.

Effects on moose survival and reproduction from increased predator access are predicted to be felt continuously, long-term in duration, and irreversible (for the Community Access Road and permanent access roads) to reversible (for access roads that will be revegetated). During construction, effects will be confined to the ungulate effects assessment Local Study Area (local effect). Considering the increase in linear feature density due to the Project will be minimal (<0.01 kilometres per square kilometre in the moose effects assessment Regional Study Area), and linear corridors will remain absent or limited throughout much of the regional area, effects from increased predator access on the ability of the regional moose population to remain self-sustaining and ecologically functional are anticipated to be negative and low in magnitude during construction.

9.4.5.3.21 Changes to Moose from Increase in Public Access

9.4.5.3.21.1 Potential Effects

Survival and Reproduction

The introduction of the new permanent Community Access Road and access roads associated with the Project are expected to improve the ability of the public to access areas throughout the ungulate effects assessment Local Study Area with limited access (via roads or trails) under existing conditions. Currently, the ungulate effects assessment Local Study Area does not have a year-round access road, and only contains a short extent of the winter access road in the southern portion of the study area (**Figure 9.4-14b**). The Project proposes to construct a 184 kilometres-long Community Access Road, which will provide year-round access throughout the ungulate effects assessment Local Study Area, stretching from Painter Lake Road to the community of Marten Falls First Nation. As such, hunting, trapping and recreational opportunities for Indigenous and non-Indigenous land users will increase within and surrounding the ungulate effects assessment Local Study Area (Rempel et al., 1997; Bowman et al., 2010; Brown et al., 2018). As a result, moose within the moose effects assessment Regional Study Area may be adversely affected by improved public access if this leads to increased hunting pressures (legal and illegal) on moose. Several

Moose are an important food source for many Indigenous communities throughout northern Ontario (LeBlanc et al., 2011; Popp et al., 2019; Priadka et al., 2022). There is no mandatory or voluntary reporting of Indigenous moose harvest, and so regional harvest levels by Indigenous hunters are uncertain. However, moose are known to be harvested and relied on as a food source by the Marten Falls First Nation and other Indigenous communities within the moose effects assessment Regional Study Area. Improved access and hunting opportunities within and surrounding the ungulate effects assessment Local Study Area is likely to result in an increase in Indigenous moose harvest, particularly in Wildlife Management Unit 17, where improved access will be greatest and the largest extent of existing high suitability habitat for moose occurs in the region (**Figure 9.4-14**). However, the magnitude of increase in Indigenous hunting that may occur due to the Project is largely unknown, particularly because current harvest levels in the region by Indigenous hunters are unknown under existing conditions.

Management of non-Indigenous hunter harvest of moose is governed by the Ontario Ministry of Natural Resources (Government of Ontario, 2025f). Applications for moose hunting tags generally remain below the annual number of tags allocated per year in Wildlife Management Units 17 and 1D by the Ontario Ministry of Natural Resources (Government of Ontario, 2025f). Increased human presence from improved access due to the Project could lead to an increase in the number applications for moose hunting

tags and successful moose harvest by non-Indigenous hunters relative to existing conditions. However, the magnitude of increase in non-Indigenous hunter harvest that will result due to the Project is largely unknown. If hunter harvest pressure by Indigenous and non-Indigenous hunters increases in response to improved access to the area, moose mortality from hunter harvest is expected to increase, which could lead to reduced moose survival and reproduction in the moose effects assessment Regional Study Area. Overharvest of moose has been identified as a variable that can influence fluctuations in moose populations (Brown, 2011; Boyce et al., 2012; Popp et al., 2019).

Increased access into the region from created roads and increased knowledge of the region due to the influx of workers and owner / operators may also increase illegal hunting of moose and other encounters between wildlife and humans that could disturb moose. However, there is uncertainty in the amount of illegal harvest occurring in the moose effect assessment Regional Study Area under existing conditions, and the extent that illegal harvest may increase due to the Project. Sensory disturbances associated with increased public use (for example, noise, smells) and hunter densities could result in habitat avoidance by moose in the ungulate effects assessment Local Study Area during construction.

Overall, the Project is expected to improve public access into the ungulate effects assessment Local Study Area during construction, which may lead to increased moose mortality from elevated hunting pressure, and ultimately could affect the survival and reproduction of the regional moose population.

9.4.5.3.21.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from increased public access on moose survival and reproduction in the ungulate effects assessment Local Study Area during construction.

The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.21.3 Predicted Residual Effects

The Project is expected to result in a measurable increase in public access and hunting opportunities for Indigenous and non-Indigenous hunters in the ungulate effects assessment Local Study Area throughout the lifetime of the Project, but particularly during operations when public vehicle use along the Community Access Road is permitted. As a result, moose mortality risk from hunter harvest is likely to increase, particularly for moose in Wildlife Management Unit 17 with home ranges near the

Community Access Road (in other words, local to regional effect). However, the magnitude of increase in Indigenous and non-Indigenous moose hunter harvest that will occur due to the Project is largely unknown. This is because current harvest levels by Indigenous hunters in the region are unknown as there is no mandatory or voluntary reporting of Indigenous moose harvest, and adaptive management of non-Indigenous moose harvest by the government is not a mitigation measure for effects from the Project and there is uncertainty if an increase in non-Indigenous hunting pressure will be managed at sustainable levels.

As such, changes to moose survival and reproduction from increased public access due to the during construction are anticipated to have a net residual effect and is carried forward to the residual effects characterization.

During construction, effects on moose survival and reproduction from increased human access would be felt continuously, are considered unlikely to occur, and would be confined to the ungulate effects assessment Local Study Area (local effect). Effects on moose are expected to be negative, long-term, and irreversible during construction. Effects from an increase in public access on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negligible in magnitude during construction.

9.4.5.3.22 Changes to Moose from Collision with Vehicles and Equipment

9.4.5.3.22.1 Potential Effects

Survival and Reproduction

During construction, there is potential for moose mortalities to occur from vehicle and equipment collisions with moose. However, only Project vehicles and equipment will be permitted within the effects assessment Construction Disturbance Area and will be required to follow speed restrictions and safe driving practices (as described further under Mitigations and Enhancement Measures). Therefore, moose mortalities due to Project vehicle or equipment collisions may occur during construction but are less likely to occur compared to Operations when public transportation on the Community Access Road will be permitted.

9.4.5.3.22.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from collisions with vehicles and equipment on moose survival and reproduction in the ungulate effects assessment Local Study Area during construction.

The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.3.22.3 Predicted Residual Effects

Implementation of mitigation is predicted to limit moose (and other wildlife) mortality from collisions with vehicles and equipment during construction. Considering that the potential increase in moose-vehicle collisions will be restricted to Project roads, particularly the Community Access Road, a decrease in survival and reproduction is predicted to be limited to moose with home ranges that overlap the effects assessment Construction Disturbance Area. Therefore, most of the effect on the moose population from collisions with vehicles is predicted to occur within the ungulate effects assessment Local Study Area with little to no measurable change at the scale of the moose effects assessment Regional Study Area.

As such, changes to moose survival and reproduction from moose-vehicle collisions during construction are anticipated to have a net residual effect and is carried forward to the residual effects characterization.

Effects will be long-term and irreversible (permanent), will be felt continuously, and are expected to be confined to the ungulate effects assessment Local Study Area (local effect). Effects from an increase in collision with vehicles on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negligible during construction (due to effective implementation of mitigation measures). If monitoring indicates that vehicle-related mortality may be strongly influencing moose populations, then additional mitigation measures will be evaluated and implemented.

9.4.5.4 Residual Effects – Operations Phase

9.4.5.4.1 Changes to Boreal Caribou and Moose from Introduction and Spread of Invasive Plant Species

9.4.5.4.1.1 Potential Effects

Habitat Availability and Distribution

During the Operations, regular vehicle traffic on the road could transport invasive plant seeds or plant parts into the ungulate effects assessment Local Study Area. If invasive plant species are introduced and spread within the effects assessment Construction Disturbance Area, this could degrade the quality of habitats used by caribou and moose (for example, suitable foraging habitat).

9.4.5.4.1.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

As per the Ministry of Transportation's Weed Control Maintenance Best Practice (MBP-320), invasive plant species in the effects assessment Construction Disturbance Area will be controlled using a combination of biological, cultural, manual, and mechanical control methods during operations (Ontario Ministry of Transportation, 2003). Herbicides (and pesticides) will not be used during maintenance.

A list of mitigation measures to control weeds is provided in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands Technical Support Document (**Appendix I**).

9.4.5.4.1.3 Predicted Residual Effects

During Operations, invasive species may occasionally be introduced within the effects assessment Construction Disturbance Area. Best management practices and the mitigation measures for controlling the spread of invasive species that will be implemented during construction are well understood and the methods have been demonstrated to be effective. The introduction of invasive plants may be higher during operations due to public use of the effects assessment Construction Disturbance Area. As such, the Project is predicted to have a net residual effect on ungulate habitat availability and distribution from the potential introduction of invasive plants during operations, and this interaction was carried forward to the residual effects characterization.

After implementation of mitigation, effects from the introduction of invasive plants during operations are predicted to be reversible over the long term and confined to the effects assessment Construction Disturbance Area. Effects from the introduction of invasive plants on the ability of caribou and moose populations in the respective effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude.

9.4.5.4.2 Changes to Boreal Caribou and Moose from Emissions of Criteria Air Contaminants

9.4.5.4.2.1 Potential Effects

Habitat Availability and Distribution

During Operations, emissions would be generated mainly from the use of fossil fuels associated with vehicles on the Community Access Road (Project and public use) and road maintenance (general, seasonal, and special maintenance). During Operations, air

criteria contaminants were predicted to be below Canadian Ambient Air Quality Standards and / or Ontario Ambient Air Quality Criteria thresholds (Atmospheric Environment Technical Support Document - Volume 1: Air Quality; **Appendix S**).

9.4.5.4.2.2 Mitigation and Enhancement Measures

A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during Maintenance. A comprehensive list of mitigation measures that will be implemented to limit air particulate emissions during operations is provided in the Atmospheric Environment Technical Support Document - Volume 1: Air Quality (**Appendix S**).

9.4.5.4.2.3 Predicted Residual Effects

As discussed in the Vegetation Technical Support Document (**Appendix J**) and the Peatlands (**Appendix I**), emissions of criteria air contaminants are anticipated to have negligible, possible effects on vegetation ecosystems, and, ultimately, ungulate habitat. As such, this interaction was determined to have no residual effects on ungulate habitat availability and distribution and is not carried forward in the assessment.

9.4.5.4.3 Changes to Boreal Caribou and Moose from Fugitive Dust Emissions

9.4.5.4.3.1 Potential Effects

Habitat Availability and Distribution

Fugitive dust emissions are expected to be produced by traffic on the Community Access Road during operations. Accumulation of airborne dust produced from the Project may result in local and direct changes to ungulate habitat as described in the Construction section above.

During Operations, threshold exceedances for the Project are predicted for particulate matter less than 2.5 micrometres, particulate matter less than 10 micrometres and total suspended particulate. The particulate matter less than 2.5 micrometres levels are predicted to reach the 24-hour and annual criteria thresholds at 115 metres and 134 metres from the road, respectively (Atmospheric Environment Technical Support Document - Volume 1: Air Quality; **Appendix S**). Levels of particulate matter less than 10 micrometres are predicted to reach the 24-hour threshold at 1,986 metres from the road. Emissions of total suspended particulate are predicted to reach the 24-hour and annual thresholds at 3,004 metres and 899 metres from the road, respectively.

9.4.5.4.3.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

A Project-specific environmental monitoring program will be developed and will contain mitigation measures to control dust and air emissions during operations. A list of mitigation measures that will be implemented to limit dust deposition during operations is provided in the Atmospheric Environment Technical Support Document - Volume 1: Air Quality (**Appendix S**).

9.4.5.4.3.3 Predicted Residual Effects

Effects on caribou and moose habitat availability and distribution from fugitive dust emissions are predicted to be larger during operations because mitigations to limit dust emissions are predicted to be more effective during construction than during operations.

Dust deposition, particularly during operations, is predicted to result in negligible but certain changes to vegetation quality in the effects assessment Local Study Area (Vegetation Technical Support Document [WSP, 2026b]; Peatlands Technical Support Document [WSP, 2026c]). As such, there is a predicted net residual effect on caribou and moose habitat availability and distribution from Operations. The residual effects from fugitive dust emissions were carried forward into the residual effects assessment characterization.

Effects from dust emissions during operations are predicted to be certain, irreversible, continuous, and confined to the ungulate effects assessment Local Study Area. Effects from dust emissions on the ability of the ungulate populations in the caribou and moose effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude.

9.4.5.4.4 Changes to Boreal Caribou and Moose from Erosion and Sedimentation

9.4.5.4.4.1 Potential Effects

Habitat Availability and Distribution

Erosion and release of sediments in watercourses and adjacent terrestrial habitat may also occur during Operations. Large precipitation events may lead to run-off from the road and sedimentation in low lying areas such as wetland and riparian habitats. Similar to construction, the effects would be localized, intermittent and vary.

9.4.5.4.4.2 Mitigation and Enhancement Measures

An environmental monitoring program will be developed and implemented during Maintenance and will contain mitigation measures to control erosion and sedimentation. Erosion and sediment control measures will be developed and implemented in accordance with Ontario Provincial Standard Specifications for erosion and sediment control measures (Ministry of Transportation, 2021a, 2021c) during Maintenance. Additionally, mitigation identified in the Ministry of Transportation's Maintenance Quality Standards and Maintenance Best Practices for highway maintenance (Ministry of Transportation, 2003) will be implemented to minimize erosion and sedimentation during operations. The mitigation measures established and refined using adaptive management during construction should be maintained during operations.

A list of mitigation measures that will be implemented during operations is provided in Vegetation Technical Support Document (**Appendix J**) and Surface Water Technical Support Document (**Appendix F**).

9.4.5.4.4.3 Predicted Residual Effects

Environmental protection and monitoring plans developed for Operations are expected to limit erosion and sedimentation. After implementing mitigation, the Project is not predicted to result in residual effects on the condition of peatland, upland, wetland and riparian ecosystems (in other words, ungulate habitat), relative to existing conditions (Vegetation Technical Support Document [**Appendix J**]). As such, this interaction was not carried forward in the assessment.

9.4.5.4.5 Changes to Boreal Caribou and Moose from Changes in Surface Water Quantity

9.4.5.4.5.1 Potential Effects

Habitat Availability and Distribution

Removal of forested and peatland habitat during construction, and subsequent conversion of treed and peatland habitats to open or shrubby habitats could result in changes to surface water quantity during operations of the Project (Surface Water Technical Support Document [**Appendix F**]). Potential effects from changes to surface water quantity on caribou and moose habitat availability and distribution are discussed in the Construction section, above.

9.4.5.4.5.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

The mitigation measures established and refined using adaptive management during Project Construction should be maintained during Operations. Follow Ontario Provincial Standard Specification 411 and regularly inspect and maintain culverts and bridges. Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during operations.

A comprehensive list of mitigation measures to limit changes to surface water quantity during operations is provided in the Surface Water Technical Support Document (**Appendix F**).

9.4.5.4.5.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**), Operations could result in small, localized changes to surface water quantity. After implementing mitigation, changes to surface water quantity are anticipated to be of negligible magnitude. As such, no net residual effects on caribou and moose habitat availability and distribution are predicted and this interaction was not carried forward in the assessment.

9.4.5.4.6 Changes to Boreal Caribou and Moose from Changes in Surface Water Quality

9.4.5.4.6.1 Potential Effects

Habitat Availability and Distribution

During Operations, mechanical vegetation maintenance activities along the right-of-way could result in changes to surface water quality. For example, organic debris may be transported to nearby waterbodies, which could increase concentrations of suspended solids in the receiving water (Surface Water Technical Support Document; **Appendix F**).

9.4.5.4.6.2 Mitigation and Enhancement Measures

Habitat Availability and Distribution

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during operations. During the

winter periods, sand will be used on the Community Access Road for de-icing instead of road salt. Herbicides (and pesticides) will not be used during Operations.

9.4.5.4.6.3 Predicted Residual Effects

As described in Surface Water Technical Support Document (**Appendix F**), the Operations of the Project is predicted to result in changes to surface water quality that are negligible in magnitude. As such, no net residual effects on ungulate habitat availability and distribution are predicted and this interaction is not carried forward into the assessment.

9.4.5.4.7 Changes to Boreal Caribou and Moose from Changes to Groundwater

9.4.5.4.7.1 Potential Effects

Habitat Availability and Distribution

Effects from changes to groundwater levels on caribou and moose habitat availability and distribution from the potential settlement of the road base structure and underlying peat material, and from potential sediment accumulation in the road base material restricting the flow of groundwater, may continue through Operations.

9.4.5.4.7.2 Mitigation and Enhancement Measures

The mitigation measures established and refined using adaptive management during construction should be maintained during operations. Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks, Fisheries and Oceans Canada, and Ontario Ministry of Natural Resources, will be followed during operations.

As discussed in the Groundwater Technical Support Document (**Appendix H**), the mitigation measures established and refined using adaptive management during construction should be maintained during Operations. It is expected that a robust monitoring program will be undertaken, and adaptive management measures implemented, as required. This monitoring program is described in more detail in the Peatlands Technical Support Document (**Appendix I**).

9.4.5.4.7.3 Predicted Residual Effects

With the implementation of mitigation measures, changes to groundwater regimes will be minimized and impacts on retained vegetation communities and ungulate habitat availability and distribution should be minimal. However, there are still anticipated to be

measurable changes to vegetation due to change to groundwater quantity, which are predicted to result in a residual effect on caribou and moose habitat availability and distribution. As such, this interaction is carried forward to the residual effects characterization.

Effects from changes to groundwater quantity are predicted to be probable, irreversible (long term), continuous, and confined to the effects assessment Local Study Area. Effects from changes to groundwater quantity on the ability of the caribou and moose populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude.

9.4.5.4.8 Changes to Boreal Caribou and Moose from Increase in Wildlife Attractants

9.4.5.4.8.1 Potential Effects

Survival and Reproduction

Wildlife may be attracted to food smells and waste, petroleum-based chemicals, and roadkill during Operations. However, the potential of attracting wildlife from food wastes, petroleum products, and gray water and sewage is expected to decrease during Operations once the temporary construction camps are decommissioned.

9.4.5.4.8.2 Mitigation and Enhancement Measures

Survival and Reproduction

The mitigation measures established and refined using adaptive management during construction should be maintained during Operations at staging areas. In addition, during Operations, inspections of the road and rest areas will occur two days of each week and, based on these inspections, debris and litter will be collected when detected (Ministry of Transportation, 2003). Additionally, Ontario Department of Highways will remove roadkill when reported by drivers on the highway or when observed during the two-time-per-week highway inspections (Ministry of Transportation, 2003). As per the Ministry of Transportation's Debris Control Maintenance Quality Standard (MQS-331), debris less than 1 metres in diameter, including roadkill, will be removed within 48 hours; debris greater than 1 metres in diameter will be removed as detected (Ministry of Transportation, 2003). Generally, roadkill will be removed from the effects assessment Construction Disturbance Area and relocated to adjacent brush areas, as per the Waste and Excess Materials Management Environmental Protection (EP-9) requirements in the Ministry of Transportation's Maintenance Manual (Ministry of Transportation, 2003). As per the Waste and Excess Materials Management Environmental Protection requirements in the Maintenance Manual, depending on the location and weather at the

time of roadkill removal, burial of small mammals occur in the roadside ditches, if this activity is permitted under a Certificate of Approval for Waste Management System (Ministry of Transportation, 2003).

Rest areas will be available every 50 kilometres along the road during operations. The rest areas will be staggered every 25 kilometres, alternating on each side of the highway. These rest areas will contain waste receptacles. As per the Ministry of Transportation's Rest Area / Picnic Site Maintenance Best Practice (MBP-325), during the rest areas operating season (in other words, months during the year when temperatures remain above 0°C and closing no sooner than October 15), litter in waste receptacles will be removed from rest areas when waste receptacles are 75 percent full (Ministry of Transportation, 2003).

During the winter periods of Operations, sand will be used on the Community Access Road for de-icing instead of road salt, if required.

9.4.5.4.8.3 Predicted Residual Effects

The implementation of mitigation measures described above, including effective waste management practices and avoidance of de-icing salt use, are expected to limit the attraction of ungulates and their predators to the effects assessment Construction Disturbance Area during operations. However, attraction to the Project could still occur. As such, the Project is expected to result in a net residual effect on caribou and moose survival and reproduction. This interaction was carried forward into the residual effects characterization.

Effects from changes to groundwater quantity are predicted to be probable, irreversible (long term), continuous, and confined to the effects assessment Local Study Area. Effects from changes to groundwater quantity on the ability of the caribou and moose populations in the effects assessment Regional Study Area to remain self-sustaining and ecologically effective are anticipated to be negative but negligible in magnitude.

9.4.5.4.9 Changes to Boreal Caribou and Moose from Blasting and Associated Fly Rock

9.4.5.4.9.1 Potential Effects

Survival and Reproduction

Explosives may be used at quarry sites to excavate materials to be used for maintenance of the Community Access Road. Blasting activities may produce fly rock that has the potential to strike ungulates in the vicinity and cause injury or death. The risk of mortality from being struck by fly rock would be greatest for ungulates who

occupy territories that overlap blasting sites. Blasting will be infrequent during Operations, and the risk of mortality to wildlife from fly rock is anticipated to be much lower during operations.

The potential effects on ungulates from the sensory disturbances associated with blasting during Operations are addressed separately under Sensory Disturbance.

9.4.5.4.9.2 Mitigation and Enhancement Measures

Survival and Reproduction

The mitigation measures established and refined using adaptive management during construction should be maintained during operations. An environmental monitoring program will be implemented during Maintenance and will include policies and actions for avoiding and minimizing the risks of blasting and blasting materials to wildlife. During Operations, quarry blasting will be suspended within 10 kilometres of known or potential High Use Areas for caribou during sensitive seasons (nursery areas: May 1 to July 14 very low tolerance, July 15 to September 15 low tolerance; winter use areas: December 1 to March 31; Ministry of Natural Resources 2013b, 2013c).

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during operations.

9.4.5.4.9.3 Predicted Residual Effects

Due to the infrequent timing of blasting, and with the implementation of mitigation, blasting and fly rock from the Project during operations is not expected to result in injury or mortality of caribou or moose. There is no net effect predicted for this Project–environment interaction on ungulate survival and reproduction. Therefore, this interaction was not carried forward in the assessment.

9.4.5.4.10 Changes to Boreal Caribou and Moose from Chemical or Hazardous Material Spills

9.4.5.4.10.1 Potential Effects

Survival and Reproduction

There is the potential for accidental spills of fuels and other materials from vehicles and vehicle collisions during road usage during Operations from malfunctions of equipment or spills during equipment or vehicle refuelling during Maintenance activities. Effects

from spills on water, soil, and vegetation quality during operations are the same as discussed in Construction.

9.4.5.4.10.2 Mitigation and Enhancement Measures

Survival and Reproduction

The mitigation measures established and refined using adaptive management during construction should be maintained during Maintenance. During Operations mitigation measures will include a posting and enforcement of a speed limit on the highway, which should reduce potential for chemical or hazardous material spills by reducing vehicle collision risk. Meet the *Transportation of Dangerous Goods Act*, Ontario Dangerous Goods Handling and Transportation Act, and the Ontario *Environmental Protection Act* for the transport, storage, and handling of fuels required for Maintenance. Also, commercial vehicles who are transporting dangerous goods on the Community Access Road should be adhering to the federal *Transportation of Dangerous Goods Act* and Ontario's Dangerous Goods Handling and Transportation Act.

9.4.5.4.10.3 Predicted Residual Effects

As discussed in the Surface Water Technical Support Document (**Appendix F**), Groundwater Technical Support Document (**Appendix H**), Physiography, Terrain, and Soils Technical Support Document (**Appendix N**), and Vegetation Technical Support Document (**Appendix J**), there are predicted to be no residual effects from chemical or hazardous material spills on surface water quality, groundwater, soil, or vegetation quality during Operations. As such, there was predicted to be no net effect on ungulate survival and reproduction, relative to existing conditions. Therefore, the potential effects of chemical or hazardous material spills were not carried forward in the assessment.

9.4.5.4.11 Changes to Boreal Caribou from Habitat Loss and Habitat Alteration

9.4.5.4.11.1 Potential Effects

Habitat Availability, Distribution, Survival and Reproduction

Although habitat will be initially removed during construction, the effects on caribou habitat availability from habitat loss will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Although habitat will be initially removed during construction, the effects on caribou habitat distribution from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

Although habitat will be initially removed during construction, the effects on caribou survival and reproduction from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

9.4.5.4.11.2 Mitigation and Enhancement Measures

Habitat Availability, Distribution and Survival and Reproduction

During Operations, ongoing use of inactive areas will be prevented through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). Marten Falls First Nation continues to engage in discussions with the Province regarding the ownership and future operations and maintenance of the Community Access Road. Access and ownership including gating security / ID system, will require further dialogue between the communities and the Province.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during operations. Additionally, a Preliminary Biodiversity Offset Plan is being developed to achieve no net loss of caribou habitat. Over the long term, measures undertaken as part of the Preliminary Biodiversity Offset Plan would be implemented to achieve a net increase in functional caribou habitat. However, because there is uncertainty in the effectiveness and timing of offset measures in the Biodiversity Offset Plan, offsetting has not been considered in the conclusion of predicted residual effects below.

The effectiveness of mitigation measures will be evaluated during Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.4.11.3 Predicted Residual Effects

The implementation of mitigation measures described above are expected to limit negative effects from habitat loss and alteration on caribou in the caribou effects assessment Regional Study Area. Direct habitat loss will occur during construction and will be confined to the effects assessment Construction Disturbance Area; indirect habitat loss will also occur within a 500 metre buffer around the effects assessment Construction Disturbance Area. The direct and indirect habitat loss that occurs during construction will be permanent and continuous for the duration of the Operations Phase of the Project.

Caribou occupying the caribou effects assessment Regional Study Area and in the Missisa range will still have an amount of undisturbed habitat that remains above the disturbance thresholds established for a self-sustaining and ecologically functional population. However, 15,047 hectares of nursery areas and 10,769 hectares of winter use areas will be removed by the Project, primarily in the Missisa range. The amount of disturbance in the Nipigon range in the existing conditions exceeds the 35 percent threshold, and the addition of the Project is predicted to increase the level of total disturbance (natural and anthropogenic combined) by approximately 0.5 percent, from 45.75 percent to 45.83 percent.

After mitigation, the Project is expected to result in a net residual effect on caribou habitat availability and distribution and survival and reproduction from habitat loss and alteration during operations. Therefore, this interaction was carried forward in the assessment.

The effects on caribou will be continuous and vary from the ungulate effects assessment Local Study Area to the caribou effects assessment Regional Study Area (for winter use and nursery areas) to beyond regional (for movement and connectivity). Some individuals that were collared in the ungulate effects assessment Local Study Area demonstrated seasonal travel east to the James Bay range and north to the Far North / eastern migratory range. The number of individuals in the population(s) who use these extended travel corridors, and the regularity of these long-distance movements, is uncertain.

Effects from habitat loss and alteration on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and of low magnitude for the Missisa range and moderate magnitude for the Nipigon range.

9.4.5.4.12 Changes to Boreal Caribou from Sensory Disturbance

9.4.5.4.12.1 Potential Effects

Habitat Availability and Distribution

During operations, sensory disturbance will mostly be produced by road use and maintenance activities. During Operations, an Average Annual Daily Traffic of 700 vehicles on the north-south section and 100 vehicles on the east-west section is anticipated by 2046. An estimated 64 percent of the traffic on the north-south segment and 3 percent of the traffic on the east-west segment of the Community Access Road is anticipated to be heavy trucks (in other words, vehicles with three or more axles designed for transportation of cargo), which will create more sensory disturbance than

light-duty and medium trucks used for personal and business use. No mining trucks are anticipated to use the east-west segment of the Community Access Road; however, the east-west segment may have commercial truck traffic accessing the aggregate facilities near the community for maintenance of the road. Although there may be periods with long intervals between vehicles along one location on the Community Access Road (infrequent disturbance), during other periods vehicles may be using the road through the day and night and the interval between vehicles would be relatively shorter resulting in frequent to continuous sensory disturbance.

As a result, sensory disturbances during Operations are certain, have the potential to negatively affect caribou distribution, movement and habitat connectivity in the ungulate effects assessment Local Study Area, and are assumed to occur continuously.

Survival and Reproduction

Although sensory disturbance will initially occur during construction, the effects on caribou survival and reproduction will continue through operations (in other words, closure and reclamation of the road is not anticipated). Sensory disturbances are predicted to decrease during operations compared to during construction.

9.4.5.4.12.2 Mitigation and Enhancement Measures

Mitigations outlined will be implemented to minimize effects from sensory disturbance on caribou habitat availability, distribution, and survival and reproduction in the ungulate effects assessment Local Study Area during operations. The effectiveness of mitigation measures will be evaluated during Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

During Operations, work will be completed as quickly as possible to reduce the duration of disturbance associated with maintenance activities. The Environmental Protection Plan will be implemented to minimize sensory disturbance by owner / operators, including prohibiting use of engine retarder brakes, enforcing speed limits, and restricting maintenance traffic to designated areas. Ongoing use of inactive areas will be prevented through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). Aerial operations will be limited when possible; when not feasible, minimum ferry altitude of 400 metres above ground level will be maintained during sensitive timing periods to reduce sensory disturbance on caribou.

Mitigations to reduce sensory disturbance by the general public during Operations are difficult to enforce; however, speed limits may reduce noise associated with vehicle

traffic. Owner / operators employed to conduct maintenance activities will follow the same mitigations as outlined for construction.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during Operations.

Additionally, a Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed to achieve no net loss of caribou habitat. Over the long term, measures undertaken as part of the Preliminary Biodiversity Offset Plan would be implemented to achieve a net increase in functional caribou habitat. However, because there is uncertainty in the effectiveness and timing of offset measures in the Preliminary Biodiversity Offset Plan, offsetting has not been considered in the conclusion of predicted residual effects below.

9.4.5.4.12.3 Predicted Residual Effects

The implementation of mitigation measures is expected to limit negative effects from sensory disturbance in the ungulate effects assessment Local Study Area, but sensory disturbance is predicted to reduce the quality of caribou habitat by causing avoidance and increased movements away from the effects assessment Construction Disturbance Area. After mitigation, the Project is expected to result in a net residual effect on caribou habitat availability and distribution and survival and reproduction from sensory disturbance during Operations. Therefore, this interaction is carried forward in the assessment.

Effects on habitat availability, distribution and survival and reproduction of Boreal caribou from sensory disturbance during Operations are predicted to be certain, irreversible, and continuous. Effects will be confined to the ungulate effects assessment Local Study Area (for habitat availability and survival and reproduction) and extend to the caribou effects assessment Regional Study Area for habitat distribution (because of the effect on connectivity). Effects from sensory disturbance on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and low in magnitude.

9.4.5.4.13 Changes to Boreal Caribou from Linear Barriers

9.4.5.4.13.1 Potential Effects

Habitat Availability and Distribution

Although linear barriers are initially created during construction, the effects on caribou habitat availability and distribution from linear barriers will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

The initial response of caribou to roads is avoidance, but over time caribou may become habituated to the presence of road and traffic depending on the intensity of activity, noise and traffic volume (Schindler et al., 2007; Vistnes and Nellemann, 2008; Polfus et al., 2011; Leblond et al., 2013; Haskell and Ballard, 2008; Johnson and Russell, 2014; Smith and Johnson, 2023). During Operations, an Average Annual Daily Traffic volume of 700 vehicles is expected on the north-south section of the Community Access Road and an Average Annual Daily Traffic volume of 100 vehicles is expected on the east-west section of the Community Access Road by 2046 (**Appendix W**).

Survival and Reproduction

Although linear barriers are initially created during construction, the effects on caribou survival and reproduction from linear barriers will continue through Operations of the Project (such as, closure and reclamation of the road is not anticipated).

9.4.5.4.13.2 Mitigation and Enhancement Measures

Mitigations will be implemented to minimize effects from linear barriers on caribou habitat availability, distribution, and survival and reproduction in the ungulate effects assessment Local Study Area during Operations. The effectiveness of mitigation measures will be evaluated during operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

During Operations of the Project, gaps will be maintained in road berms and snowbanks to facilitate wildlife crossing at drainages, wildlife trails, strategic crossing points informed by movement data and Indigenous Knowledge, or connected habitat patches so that caribou movements across roads are not blocked. Snowbanks will be limited as much as possible and to a height of less than 1.6 metres. Snow clearing along the access roads will incorporate road pull-outs at regular intervals to provide refuge for wildlife moving along the Community Access Road corridor. Posted traffic speeds will be enforced.

Modified traffic patterns and road closures are common mitigations to reduce the effects of linear barriers associated with operation of winter use industry roads and mine roads,

but are not feasible mitigations to implement during operations of a Community Access Road.

9.4.5.4.13.3 Predicted Residual Effects

The implementation of mitigation measures is expected to limit negative effects from linear barriers in the ungulate effects assessment Local Study Area and caribou effects assessment Regional Study Area. However, the addition of a new permanent road is predicted to result in alteration of caribou movement patterns and reduce the quality of caribou habitat by causing avoidance of the Construction Disturbance Area, particularly for caribou that move between the Missisa and Ozshiki ranges and Missisa and Nipigon ranges.

After mitigation, the Project is expected to result in a net residual effect on caribou habitat availability and distribution and survival and reproduction from linear barriers during Operations. Therefore, this interaction was carried forward in the assessment.

Effects on habitat availability, distribution, and survival and reproduction of Boreal caribou from increased linear barriers during construction and operations are predicted to be continuous and probable. Effects will be local for habitat availability and regional to beyond regional for habitat distribution and survival and reproduction. During Operations, when temporary access roads are revegetated, the effects will be long term and reversible for those revegetated access roads and long term and irreversible for the Community Access Road and permanent access roads. Effects from linear barriers on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and high in magnitude.

9.4.5.4.14 Changes to Boreal Caribou from Increased Predator Access

9.4.5.4.14.1 Potential Effects

Survival and Reproduction

Although increased predation risk will initially occur during construction, the effects on caribou survival and reproduction will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

9.4.5.4.14.2 Mitigation and Enhancement Measures

Mitigations outlined will be implemented to minimize effects from increased predator access on caribou survival and reproduction in the ungulate effects assessment Local Study Area during Operations. The effectiveness of mitigation measures will be

evaluated during Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

To minimize ongoing attraction of predators to the Project area, de-icing salts will not be used on the unpaved Community Access Road, road kill will be cleaned up following best management practices outlined by Ontario's Ministry of Transportation and wildlife access to waste will be restricted. The ongoing use of inactive areas by predators will be minimized through physical control measures such as rollback, removal of creek crossings, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access.

9.4.5.4.14.3 Predicted Residual Effects

Implementing the mitigation measures described above is expected to limit the negative effects from increased predation risk to caribou due to the increase in linear features. The largest risk to caribou would likely occur during Operations when predators are more likely to use the decommissioned access roads for travel (in other words, forage) may attract moose. However, it is uncertain how frequently predators would use the access roads and Community Access Road, and the level of increase in encounter rates that would occur (effect is likely). The effect is expected to be stronger in the southern portion of the study areas during the early stages of regeneration and weaken as the vegetation transitions into mature forest and becomes less quality forage for moose.

Considering the potential increase in predator encounters will be restricted to Project roads and adjacent habitat, an increase in predation risk is predicted to be limited to caribou with home ranges that overlap the ungulate effects assessment Local Study Area. Most of the effect on the caribou population from increased predator access is predicted to occur within the ungulate effects assessment Local Study Area with little to no measurable change at the scale of the caribou effects assessment Regional Study Area.

After mitigation, the Project is expected to result in a net residual effect on caribou survival and reproduction from increased predator access during construction and operations. Therefore, this interaction was carried forward in the assessment.

Effects on reproduction and survival of Boreal caribou from increased predator access are predicted to be probable, continuous, and confined to the ungulate effects assessment Local Study Area. During Operations, when temporary access roads are revegetated, the effects will be long term and reversible for those revegetated access roads and long term and irreversible for the Community Access Road and permanent access roads. Effects from increased predation on the ability of the caribou populations

in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and negligible in magnitude.

9.4.5.4.15 Changes to Boreal Caribou from Increase in Public Access

9.4.5.4.15.1 Potential Effects

Survival and Reproduction

Although increase in public access will initially occur during construction, the effects on caribou survival and reproduction will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated). The effects will be stronger during operations when there are more people using the road.

9.4.5.4.15.2 Mitigation and Enhancement Measures

Mitigations outlined will be implemented to minimize effects from increased public access on caribou survival and reproduction in the ungulate effects assessment Local Study Area during Operations. The effectiveness of mitigation measures will be evaluated during Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

During Operations, the Community Access Road will be accessible to the public but access roads for aggregate areas and other infrastructure required for Employees will be prohibited from hunting or carrying firearms while conducting Maintenance activities. Marten Falls First Nation continues to engage in discussions with the Province regarding the ownership and future operations of the Community Access Road. Access and ownership including gating security / ID system, will require further dialogue between the communities and the Province.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction and operations.

9.4.5.4.15.3 Predicted Residual Effects

The Project is expected to result in a measurable change in public access in the ungulate effects assessment Local Study Area relative to the existing environment. The increase in people in the area during the Project lifespan could result in a minor increase in illegal harvesting of animals. The largest risk to caribou would occur during operations when mitigations are more difficult to enforce.

After mitigation, the Project is expected to result in a net residual effect on caribou survival and reproduction from increased public access during construction and operations. Therefore, this interaction was carried forward in the assessment.

Effects from increases in public access are predicted to be possible during operations, irreversible, continuous, and confined to the ungulate effects assessment Local Study Area. Effects from increased hunting and poaching on the ability of the caribou populations in the caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be low in magnitude during Operations.

9.4.5.4.16 Changes to Boreal Caribou from Collisions with Vehicles and Equipment

9.4.5.4.16.1 Potential Effects

Survival and Reproduction

Although increased risk of collisions with vehicles and equipment will initially occur during construction, the effects on caribou survival and reproduction will continue through Operations of the Project (in other words, closure and reclamation of the road is not anticipated).

It is expected that there will be an increase in light and all-terrain vehicles and snowmachines in addition to vehicles that transport heavy materials, equipment and fuel. During Operations, an Average Annual Daily Traffic of 700 vehicles on the north-south section and 100 vehicles on the east-west section by 2046 was conservatively estimated (**Appendix W**). An estimated 64 percent of the traffic on the north-south segment and 3 percent of the traffic on the east-west segment of the Community Access Road is anticipated to be heavy trucks (in other words, vehicles with three or more axles designed for transportation of cargo). No mining trucks are anticipated to use the east-west segment of the Community Access Road during Operations; however, the east-west segment may have commercial truck traffic accessing the aggregate facilities near the community of Marten Falls First Nation for maintenance of the Community Access Road.

Limited information is available on the anticipated day / night traffic distribution on the Community Access Road during operations, although it is reasonable to assume that traffic volume will be higher during daytime (**Appendix W**). Although there may be periods of long intervals between vehicles along one location on the Community Access Road (possible occurrence of collision), during other periods vehicles may be using the road through the day and night and the interval between vehicles would be relatively

shorter and increase the likelihood of caribou-vehicle collisions (in other words, probable).

Traffic in the effects assessment Construction Disturbance Area may result in avoidance by caribou during Operations. Avoidance of traffic by caribou would decrease the potential for injury or mortality from vehicle collisions. However, the ability of caribou to avoid or move away from the Community Access Road may be constrained during certain life-history periods or stages. Although caribou are extremely mobile, they may be adversely influenced immediately prior to and for a short period after calving when their movements are constrained. An increase in vehicles and traffic during the calving and post-calving season can increase the risk of injury or mortality to adults and their young.

9.4.5.4.16.2 Mitigation and Enhancement Measures

During Operations, the ongoing use of inactive areas by the public will be minimized through physical control measures such as rollback, removal of creek crossings, felling of timber across temporary access roads, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access. Progressive reclamation and revegetation will be implemented as non-permanent features will be decommissioned and reclaimed or revegetated naturally. This will reduce the amount of humans / vehicles on inactive roads and trails and ultimately minimize the number of collisions.

During Operations, mitigation measures applicable to non-commercial traffic will include signage in areas where wildlife are regularly observed and reduced speed limits in Category 1 caribou habitat areas. Additional mitigation for commercial traffic will include reduced speed limits on the entire road, communication of wildlife presence between drivers, and mandatory reporting of wildlife incidents. Gaps in snowbanks will be ploughed at least every 1 kilometres apart and maintained by road maintenance crews throughout the winter season. Marten Falls First Nation continues to engage in discussions with the Province regarding the ownership and future operations of the Community Access Road. Access and ownership including gating security / ID system, will require further dialogue between the communities and the Province.

Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction and operations.

Additionally, a Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed to achieve no net loss of caribou habitat. Over the long term, measures undertaken as

part of the Preliminary Biodiversity Offset Plan would be implemented to achieve a net increase in functional caribou habitat. However, because there is uncertainty in the effectiveness and timing of offset measures in the Preliminary Biodiversity Offset Plan, offsetting has not been considered in the conclusion of predicted residual effects below.

The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.4.16.3 Predicted Residual Effects

Implementation of mitigation is predicted to limit caribou (and other wildlife) mortality from collisions with vehicles and equipment during Operations. The largest risk to caribou from collisions with vehicles would occur during Operations when traffic volume is highest and there are less enforceable mitigations to implement. Considering the potential increase in caribou-vehicle collisions will be restricted to Project roads, a decrease in survival and reproduction is predicted to be limited to caribou with home ranges that overlap the ungulate effects assessment Local Study Area. The increase in mortality of caribou from vehicle collisions is predicted to be additive relative to other mortality factors and have little to no to effect on population survival and reproduction (in other words, lambda) at the scale of the caribou effects assessment Regional Study Area. If monitoring indicates that vehicle-related mortality may be strongly influencing caribou populations, then additional mitigation measures would be evaluated and implemented.

After mitigation, the Project is expected to result in a net residual effect on caribou survival and reproduction from collisions with vehicles and equipment during Operations. Therefore, this interaction was carried forward in the assessment.

Effects are predicted to be probable during operations, irreversible, continuous, and confined to the ungulate effects assessment Local Study Area. Effects from collisions with vehicles and equipment on the ability of the caribou populations in the caribou effects assessment Regional Study Areas to remain self-sustaining and ecologically functional are anticipated to be low to moderate magnitude during Operations.

9.4.5.4.17 Changes to Moose from Habitat Loss and Habitat Alteration

9.4.5.4.17.1 Potential Effects

Habitat Availability

Although habitat will be initially removed during construction, the effects on moose habitat availability from habitat loss will continue indefinitely throughout Operations of

the Project (in other words, closure and reclamation of the Community Access Road, its associated right-of-way and aggregate areas are not anticipated). An exception to this is that temporary features (for example, laydown areas, construction camps, some access roads) will be decommissioned and reclaimed or left to revegetate naturally are anticipated to provide functional moose habitat after six to ten years once low shrubs have established (Nelson et al. 2008). Reclamation is assumed to reverse the effects of land clearing; however, reclaimed habitats are expected to differ structurally from existing conditions. Reclaimed areas that are exposed to sensory disturbance associated with Operations may continue to be avoided by moose despite successful establishment of forage habitat.

Habitat Distribution

Although habitat will be initially removed and fragmented during construction, the effects on moose habitat distribution from habitat loss is expected to continue indefinitely throughout Operations of the Project (in other words, closure and reclamation of the Community Access Road and its associated right-of-way are not anticipated). As discussed above under Habitat Availability, reclamation of temporary features is expected to provide functional moose habitat after six to ten years (Nelson et al., 2008). However, temporary features are less likely to have a measurable change on moose habitat connectivity compared to the Project's permanent features. As a result, the effects from changes to moose habitat distribution and connectivity are expected to continue into Operations, despite the reclamation of temporary features.

The introduction of Project linear features also has the potential to negatively affect moose through increases in predation risk, hunter harvest pressure, and moose-vehicle collisions.

Survival and Reproduction

Although habitat will be initially removed during construction, the effects on moose survival and reproduction from habitat loss and alteration will continue through Operations of the Project (in other words, closure and reclamation of the Community Access Road and its associated right-of-way is not anticipated).

9.4.5.4.17.2 Mitigation and Enhancement Measures

Habitat Availability

Mitigation measures outlined in **Section 9.4.5.3.11** will be implemented to avoid, minimize, and restore the effects from habitat loss and alteration on moose habitat availability, distribution, and survival and reproduction in the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area

(specifically in Wildlife Management Unit 17 where a higher proportion of habitat loss and alteration will occur). Further, Marten Falls First Nation has proposed a number of mitigation measures to limit the effects on wildlife and their habitats from habitat loss and alteration, which are outlined in Marten Falls First Nation (2023).

The effectiveness of mitigation measures will be evaluated during Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.4.17.3 Predicted Residual Effects

A small amount of potential quality moose habitat that will be directly and indirectly lost or altered during construction, relative to the amount available in existing conditions. Specifically, the Project is predicted to directly remove 4,462 hectares of high and moderate suitability moose habitat that overlaps the effects assessment Construction Disturbance Area. This represents a 1.2 percent and <0.1 percent decrease in high and moderate habitat in the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area, respectively. Direct habitat loss is confined to the effects assessment Construction Disturbance Area. An additional 23,812 hectares of high and moderate suitability habitat is expected to be indirectly (effectively) lost or affected within the 500 metre buffer (zone of influence) around the effects assessment Construction Disturbance Area, which represents a potential 6.3 percent and 0.2 percent decrease in high and moderate suitability habitat in the ungulate effects assessment Local Study Area and moose effects assessment Regional Study Area, respectively.

Overall, high and moderate suitability habitats are expected to decrease in availability by 7.5 percent in the ungulate effects assessment Local Study Area and 0.3 percent in the moose effects assessment Regional Study Area due to direct and indirect habitat loss or alteration associated with the Project. Therefore, a large proportion of suitable moose habitat is expected to remain undisturbed and connected in the ungulate effects assessment Local Study Area and the moose effects assessment Regional Study Area during Operations.

The implementation of mitigation measures is expected to reduce negative effects from the Project on moose habitat availability, habitat distribution, and survival and reproduction; however, effects on moose from habitat loss and alteration cannot be avoided or mitigated entirely. Therefore, a net residual effect on moose is expected during Operations from habitat loss and alteration. Residual effects from habitat loss and alteration were carried forward into characterization of residual effects.

Effects will be confined to the ungulate effects assessment Local Study Area (habitat availability, survival, and reproduction) and the moose effects assessment Regional Study Area (habitat connectivity and movement). Effects from direct habitat loss and alteration on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negative and low in magnitude.

9.4.5.4.18 Changes to Moose from Sensory Disturbance

9.4.5.4.18.1 Potential Effects

Habitat Availability and Distribution

During Operations, sensory disturbances and human activity produced by the Project will be associated with vehicle traffic on the Community Access Road, maintenance of the road, and continued use of some quarries. Sensory disturbance produced by the Project, such as noise and vibrations, are expected to decrease during operations compared to Construction.

Noise modelling indicates that vehicle traffic on the Community Access Road during operations will result in noise levels ranging from 41 to 53 A-weighted decibels at the edge of the effects assessment Construction Disturbance Area. Noise levels at 500 metres from the effects assessment Construction Disturbance Area (zone of influence) are predicted to range between 38 to 41 A-weighted decibels, which are below the daytime level of 45 A-weighted decibels that is typical of rural and remote areas, as described in the Health Canada Noise Guidance (Health Canada, 2023). In addition, ground vibrations induced by vehicle traffic during operations are predicted to be negligible beyond 25 metres of the right-of-way of the Community Access Road (Acoustic and Vibration Technical Support Document [**Appendix P**]).

The continued operation of quarries during Operations is predicted to emit noise levels between 55 to 77 A-weighted decibels at the edge of the effects assessment Construction Disturbance Area (Acoustic and Vibration Technical Support Document [**Appendix P**]). Existing vibration levels are expected to increase, on occasion, due to quarry blasting activities but blast-induced vibration will be temporary in nature, occur only during specific activities, and would be limited to the vicinity of Project quarries. As described for Construction, ground vibration from occasional quarry blasting during operations is expected to produce a short-term increase in ground vibration and air overpressure within the vicinity of a blast source (Acoustic and Vibration Technical Support Document [**Appendix P**]).

The predicted noise levels near the road and public presence during operations are still expected to affect moose habitat availability, behaviour and movement in the ungulate

effects assessment Local Study Area. As such, it is conservatively assumed that habitat within the 500 metre zone of influence around the effects assessment Construction Disturbance Area could remain indirectly (effectively) lost or degraded due to sensory disturbance during Operations, as described for Construction.

Sensory disturbance effects from vehicle traffic are expected to be felt continuously during Operations, although traffic volumes will vary temporally and spatially. Traffic volumes are expected to be greatest on the north-south section of the Community Access Road compared to the east-west section that connects to the Marten Falls First Nation community.

Changes to moose behaviour, movement, and habitat availability and distribution from sensory disturbance during operations are considered probable (in other words, effect is likely to occur) with the potential for some individuals to adapt to vehicle traffic.

Survival and Reproduction

Although sensory disturbance from the Project will initially occur during construction, the effects on moose survival and reproduction will continue through Operations of the Project (in other words, closure and reclamation of the Community Access Road is not anticipated). As described under Habitat Availability and Distribution, sensory disturbances are predicted to decrease during Operations with vehicle traffic as the primary source of sensory disturbance.

9.4.5.4.18.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from sensory disturbance on moose habitat availability and distribution and survival and reproduction in the ungulate effects assessment Local Study Area Operations.

The effectiveness of mitigation measures will be evaluated Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.4.18.3 Predicted Residual Effects

The implementation of mitigation measures is expected to limit negative effects on moose habitat availability, habitat distribution, and survival and reproduction from sensory disturbance; however, effects on moose from sensory disturbance cannot be entirely avoided or mitigated. As such, sensory disturbances from construction activities and operation of the Community Access Road are predicted to reduce the suitability of moose habitat by causing avoidance and movements away from the effects assessment Construction Disturbance Area. Therefore, changes to moose habitat availability, habitat distribution, and survival and reproduction from sensory disturbance during Operations

are anticipated to have a net residual effect on moose. Residual effects from sensory disturbance were carried forward into the characterization of residual effects.

Effects from sensory disturbance are probable and will be confined to the ungulate effects assessment Local Study Area (in other words, local scale effect). Effects will be continuous during Operations. Effects from Project-related sensory disturbance on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negative and low in magnitude during Operations.

9.4.5.4.19 Changes to Moose from Linear Barriers

9.4.5.4.19.1 Potential Effects

Habitat Availability and Distribution

During Operations, some of the access roads developed during construction will be decommissioned. Barriers will be placed at the start of these access roads and public access will be prohibited, which is anticipated to limit vehicle traffic and human activity. Moose have been found to exhibit both avoidance and selection of secondary roads in areas with low human activity (Laurian et al., 2008a,b; Eldegard et al., 2012; Bowman et al., 2010; Dickie et al., 2020). There is potential for moose to use decommissioned access roads as travel corridors (Dickie et al., 2020) or to use roadside habitat (ditches) along these access roads to feed on new vegetation growth in spring (Rea et al., 2010; Bowman et al., 2010; Jakobsson et al., 2018). However, it is possible that some individuals in the ungulate effects assessment Local Study Area will avoid decommissioned and revegetated access roads because moose generally perceive roads as risky, especially if predators use them for travel (Dickie et al., 2020).

The effects of these linear features on moose movement and habitat connectivity are expected to persist through Operations.

Survival and Reproduction

Project linear features have the potential to cause increased moose mortality risk during Operations from an increase in moose-vehicle collisions, hunting pressure (from increased public access) and predator encounters (from increased predator access).

9.4.5.4.19.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from linear barriers on moose habitat availability and distribution and survival and reproduction in the ungulate effects assessment Local Study Area during construction and / or Operations.

At watercourse crossings that occur within Category 1 caribou habitat and are on the north-south segment of the Preferred Route and at watercourse crossings that occur within Category 1 habitat and on the east-west segment of the preferred modified bridge and bridge embankments will be designed to incorporate terrestrial pathways adjacent to the aquatic habitat and allow for ungulate passage, where feasible given land cover considerations. These design features include increasing the height of bridge to minimum 4 metres vertical clearance, using natural substrates on the bridge embankments and under the bridge, allow for an unobstructed line of sight on either side of the bridge, and clear and maintain the minimum width of right-of-way at bridge crossings. In other locations along the Community Access Road where frequent crossings of species at risk are anticipated [in other words, in caribou Category 1 habitat (**Figure 9.4-7** to **Figure 9.4-9**) and moose high suitability habitats (**Figure 9.4-14**)], reduced speed limits will be implemented and wildlife-friendly road embankments with gentle slopes (in other words, gradual incline) and smooth crush material will be constructed to encourage safe crossing. Specific sites will be informed by caribou collar data, habitat modelling and Indigenous Knowledge.

9.4.5.4.19.3 Predicted Residual Effects

The implementation of mitigation measures is expected to limit negative effects on moose habitat availability, habitat distribution, and survival and reproduction from introducing linear barriers in the ungulate effects assessment Local Study Area during Operations. However, the addition of the permanent, Community Access Road is expected to affect moose movements and behaviour (in other words, inducing avoidant behaviour) within and surrounding the ungulate effects assessment Local Study Area (in other words, local to regional scale effect). Reduced moose mobility and habitat connectivity is expected to be most affected within the southcentral portion of the ungulate effects assessment Local Study Area where a large extent of high suitability habitat will be fragmented (**Figure 9.4-14b**).

As such, changes to moose habitat availability, habitat distribution, and survival and reproduction from linear barriers during Operations are anticipated to have a net residual effect and is carried forward to the residual effects characterization.

Effects on moose habitat availability and survival and reproduction are expected to be felt by moose with home ranges that overlap the ungulate effects assessment Local Study Area (local effect) but also may affect the movement and connectivity of animals in the surrounding habitats of the moose effects assessment Regional Study Area (regional effect). Effects from linear barriers on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negative and low in magnitude during Operations.

9.4.5.4.20 Changes to Moose from Increase in Predator Access

9.4.5.4.20.1 Potential Effects

Survival and Reproduction

There is potential that the increase in decommissioned access roads during Operations will improve predator mobility and increase encounter rates between predators and moose in the ungulate effects assessment Local Study Area (James and Stuart-Smith, 2000; Whittington et al., 2011). Consequently, predation risk for moose may increase, leading to a decline in moose survival and reproduction at the local scale.

Additionally, moose are often attracted to revegetating access roads to browse on early seral vegetation once it becomes available about 6 to 10 years following revegetation. If moose occupy revegetating access roads for foraging, and predators use these access roads for travel, this could result in an increase in predator-moose encounters and predation events. This potential effect is expected to be likely to occur and would be felt continuously by moose during the length of time where early to mid-seral vegetation is present on revegetating access roads. Predators are expected to continue avoiding the Community Access Road during Operations due to vehicle traffic and human activity that will occur along the road.

Overall, the increase in linear features (mainly access roads) due to the Project could lead to an increase in moose predation risk from increased predator access in the ungulate effects assessment Local Study Area. Potential increases in moose predation is more likely to occur during Operations when decommissioned access roads with little human activity are available for predators to travel, compared to during construction. A measurable change in survival and reproduction in the regional population within the moose effects assessment Regional Study Area may also be detected depending on the magnitude, duration and frequency of the local change in predation.

9.4.5.4.20.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from increased predator access on moose survival and reproduction in the ungulate effects assessment Local Study Area during Operations.

The effectiveness of mitigation measures will be evaluated during Operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

9.4.5.4.20.3 Predicted Residual Effects

Implementing mitigation measures is expected to reduce the negative effects on moose survival and reproduction from an increase in predator access (from introduced Project linear features). The potential for increases in moose mortalities due to increased predator access will be greatest during Operations when predators are more likely to use decommissioned access roads for travel (in other words, forage) may attract moose. However, it is uncertain how frequently predators will use access roads and the level of increase in encounter rates that will result (effect is likely but uncertain).

Considering that potential increases in predator encounters will be restricted to Project roads and adjacent habitats, effects from an increase in predator access due to the Project will be largely constrained to the ungulate effects assessment Local Study Area. Therefore, an increase in predation risk is expected to primarily affect moose with home ranges that overlap the ungulate effects assessment Local Study Area, with little to no measurable change to the moose population at the scale of the moose effects assessment Regional Study Area. Changes to moose survival and reproduction from increased predator access due to the Project are anticipated to have a net residual effect and is carried forward to the residual effects characterization.

Effects on moose survival and reproduction from increased predator access are predicted to be felt continuously, long-term in duration, and irreversible (for the Community Access Road and permanent access roads) to reversible (for access roads that will be revegetated). During Operations, effects will be confined to the ungulate effects assessment Local Study Area (local effect). Considering the increase in linear feature density due to the Project will be minimal (<0.01 kilometres per square kilometre in the moose effects assessment Regional Study Area), and linear corridors will remain absent or limited throughout much of the regional area, effects from increased predator access on the ability of the regional moose population to remain self-sustaining and ecologically functional are anticipated to be negative and low in magnitude during Operations.

9.4.5.4.21 Changes to Moose from Increase in Public Access

9.4.5.4.21.1 Potential Effects

Survival and Reproduction

Although increase in public access will initially occur during construction, the effects on moose survival and reproduction will continue through Operations of the Project. The effects will be stronger during operations when public travel along the Community

Access Road is permitted, compared to Construction when public access will be prohibited.

9.4.5.4.21.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from increased public access on moose survival and reproduction in the ungulate effects assessment Local Study Area during Operations.

9.4.5.4.21.3 Predicted Residual Effects

The Project is expected to result in a measurable increase in public access and hunting opportunities for Indigenous and non-Indigenous hunters in the ungulate effects assessment Local Study Area throughout the lifetime of the Project, but particularly during operations when public vehicle use along the Community Access Road is permitted. As a result, moose mortality risk from hunter harvest is likely to increase, particularly for moose in Wildlife Management Unit 17 with home ranges near the Community Access Road (in other words, local to regional effect). However, the magnitude of increase in Indigenous and non-Indigenous moose hunter harvest that will occur due to the Project is largely unknown. This is because current harvest levels by Indigenous hunters in the region are unknown as there is no mandatory or voluntary reporting of Indigenous moose harvest, and adaptive management of non-Indigenous moose harvest by the government is not a mitigation measure for effects from the Project and there is uncertainty if an increase in non-Indigenous hunting pressure will be managed at sustainable levels.

As such, changes to moose survival and reproduction from increased public access due to the during Operations are anticipated to have a net residual effect and is carried forward to the residual effects characterization.

During Operations, effects on moose survival and reproduction from increased human access is expected to be felt continuously, is probable, and would be confined to the ungulate effects assessment Local Study Area with potential to extend into the moose effects assessment Regional Study Area (local to regional effect). Effects on moose are expected to be negative, long-term, and irreversible during Operations. However, there is high uncertainty in the magnitude of predicted effects of increased human access and associated increase in potential hunter harvest on moose survival and reproduction during Operations. As a result a precautionary approach was applied and it was assumed that Project-related changes to moose population survival and reproduction from increased access could reach unsustainable levels and lead to decreased resilience and maintenance of the self-sustaining and ecologically effective regional moose population.

9.4.5.4.22 Changes to Moose from Collision with Vehicles and Equipment

9.4.5.4.22.1 Potential Effects

Survival and Reproduction

The likelihood of moose-vehicle collisions is expected to be greatest in Operations due to the higher traffic volumes anticipated during this Phase. Mortality events that occur during Operations are more likely to be attributed to collisions with public and industry vehicles that are not associated with the Project, rather than Project-vehicles.

Moose-vehicle collision risk is expected to be greatest in Wildlife Management Unit 17 along the southern segments of the Community Access Road where the largest concentration of high suitability winter habitat in the ungulate effects assessment Local Study Area occurs, and where the greatest traffic volumes are anticipated (**Figure 9.4-14**). Moose can be attracted to new vegetation growth along roadsides (for example, ditches) in the spring (Brown et al., 2012; Gagnon et al., 2024). Given this, an increased risk of moose-vehicle collisions may occur along segments of the Community Access Road where quality forage is available next to the road. However, moose often avoid roads with high traffic volume (Laurian et al., 2008b; Bowman et al., 2010; Fahrig and Rytwinski, 2009), and thus, some individuals are expected to avoid the Community Access Road, which would likely reduce the number of vehicle-moose collisions.

9.4.5.4.22.2 Mitigation and Enhancement Measures

Mitigations outlined in **Section 9.4.5.3.11** will be implemented to minimize effects from collisions with vehicles and equipment on moose survival and reproduction in the ungulate effects assessment Local Study Area during Operations.

9.4.5.4.22.3 Predicted Residual Effects

Implementation of mitigation is predicted to limit moose (and other wildlife) mortality from collisions with vehicles and equipment during Operations. The largest risk to moose from collisions with vehicles is anticipated to occur during Operations when public traffic volume is highest and there are less enforceable mitigations to implement. Considering that the potential increase in moose-vehicle collisions will be restricted to Project roads, particularly the Community Access Road, a decrease in survival and reproduction is predicted to be limited to moose with home ranges that overlap the effects assessment Construction Disturbance Area. Therefore, most of the effect on the moose population from collisions with vehicles is predicted to occur within the ungulate effects assessment Local Study Area with little to no measurable change at the scale of the moose effects assessment Regional Study Area.

As such, changes to moose survival and reproduction from moose-vehicle collisions during Operations are anticipated to have a net residual effect and is carried forward to the residual effects characterization.

Effects will be long-term and irreversible (permanent), will be felt continuously, and are expected to be confined to the ungulate effects assessment Local Study Area (local effect). Effects from an increase in collision with vehicles on the ability of the regional moose population to remain self-sustaining and ecologically effective are anticipated to be negative and low to moderate in magnitude during Operations. If monitoring indicates that vehicle-related mortality may be strongly influencing moose populations, then additional mitigation measures will be evaluated and implemented.

9.4.5.5 Summary of Residual Effects

Table 9.4-14 provides a summary of the potential effects on ungulates, mitigation measures, and residual effects. Detailed information is included in **Appendix M**.

Table 9.4-14: Summary of Residual Effects for Ungulates and Characterization

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
• **Caribou and Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Introduction and spread of invasive plant species—Can affect plant community composition, which can affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures to control weeds during construction is provided in the Vegetation Technical Support Document (Appendix J) and Peatlands Technical Support Document (Appendix I). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.	• Residual changes in caribou and moose habitat availability and distribution due to introduction and spread of invasive plant species	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration / Reversibility: Short term / Reversable • Frequency: Infrequent • Likelihood: Possible • Significance: Not Significant • Uncertainty: Low • Direct / Indirect: Indirect
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Introduction and spread of invasive plant species—Can affect plant community composition, which can affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures to control weeds during Operations is provided in the Vegetation Technical Support Document (Appendix J) and Peatlands Technical Support Document (Appendix I). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during Operations	• Residual changes in caribou and moose habitat availability and distribution due to introduction and spread of invasive plant species	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration / Reversibility: Long term / Reversable • Frequency: Infrequent • Likelihood: Possible • Significance: Not Significant • Uncertainty: Low • Direct / Indirect: Indirect
• **Caribou and Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and	• Construction	• Emissions of Criteria Air Contaminants—Deposition of suspended solids in criteria air contaminant emissions (for example, potential acid inputs) may change soil quality and vegetation and affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures that will be implemented to limit dust deposition during construction is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).	• No residual effect anticipated	• No residual effect anticipated

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
	surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas					
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Emissions of Criteria Air Contaminants—Deposition of suspended solids in criteria air contaminant emissions (for example, potential acid inputs) may change soil quality and vegetation and affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures that will be implemented to limit dust deposition during Operations is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).	• No residual effect anticipated	• No residual effect anticipated
• **Caribou and Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Temporary concrete batch plants • Pits and quarries • Drilling / blasting / aggregate production • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Fugitive Dust Emissions — Fugitive dust emissions and deposition may cause changes in soils and vegetation, which can adversely affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures that will be implemented to limit dust deposition during construction is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).	• Residual changes to caribou and moose habitat availability and distribution from dust emissions and deposition	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Local Study Area • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Certain • Significance: Not Significant • Uncertainty: Low • Direct / Indirect: Direct
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Fugitive Dust Emissions — Fugitive dust emissions and deposition may cause changes in soils and vegetation, which can adversely affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures that will be implemented to limit dust deposition during Operations is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).	• Residual changes to caribou and moose habitat availability and distribution from dust emissions and deposition	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Local Study Area • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Certain • Significance: Not Significant • Uncertainty: Low • Direct / Indirect: Direct

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
• **Caribou and Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Temporary concrete batch plants • Pits and quarries • Drilling / blasting / aggregate production • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Erosion and sedimentation—Vegetation clearing, earth moving, pit and quarry development and other Project activities can result in the release of sediment, which may change the composition and function of vegetation communities and affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures to limit changes from erosion and sedimentation during construction is provided in the Vegetation Technical Support Document (Appendix J) and the Surface Water Technical Support Document (**Appendix F**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.	• No residual effect anticipated	• No residual effect anticipated
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Erosion and sedimentation—Vegetation clearing, earth moving, pit and quarry development and other Project activities can result in the release of sediment, which may change the composition and function of vegetation communities and affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures to limit changes from erosion and sedimentation during Operations is provided in the Vegetation Technical Support Document (**Appendix J**) and the Surface Water Technical Support Document (**Appendix F**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during Operations.	• No residual effect anticipated	• No residual effect anticipated
• **Caribou and Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration	• Construction	• Surface water quantity—Alteration of surface water drainage patterns, flows, and levels that can cause changes to soils and vegetation, which can affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures to limit changes to surface water quantity during construction is provided in the Surface Water Technical Support Document (**Appendix F**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.	• No residual effect anticipated	• No residual effect anticipated

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
	• Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas					
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Surface water quantity—Alteration of surface water drainage patterns, flows, and levels that can cause changes to soils and vegetation, which can affect ungulate habitat availability and distribution.	• Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during Operations. • A comprehensive list of mitigation measures to limit changes to surface water quantity during Operations is provided in the Surface Water Technical Support Document (**Appendix F**).	• No residual effect anticipated	• No residual effect anticipated
• **Caribou and Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Surface water quality—Changes in surface water quality from contact with the road surface and quarries could adversely affect ungulate habitat availability and distribution	• A comprehensive list of mitigation measures to limit changes to surface water quality during construction and operations is provided in the Surface Water Technical Support Document (**Appendix F**). • Follow best management practices and environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Fisheries and Oceans Canada, Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources.	• No residual effect anticipated	• No residual effect anticipated
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Surface water quality—Changes in surface water quality from contact with the road surface and quarries could adversely affect ungulate habitat availability and distribution	• A comprehensive list of mitigation measures to limit changes to surface water quality during Operations is provided in the Surface Water Technical Support Document (**Appendix F**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during Operations.	• No residual effect anticipated	• No residual effect anticipated

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
• **Caribou and Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Changes to Groundwater — Alteration of groundwater drainage and infiltration patterns, flows, and levels that can cause changes to soils and vegetation, which can affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures to limit changes to groundwater quantity during construction is provided in the Groundwater Technical Support Document (**Appendix H**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.	• Residual changes to caribou and moose habitat availability and distribution from changes to groundwater quantity.	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Local Study Area • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Probable • Significance: Not Significant • Uncertainty: Moderate • Direct / Indirect: Direct
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route Maintenance	• Operations	• Changes to Groundwater — Alteration of groundwater drainage and infiltration patterns, flows, and levels that can cause changes to soils and vegetation, which can affect ungulate habitat availability and distribution.	• A comprehensive list of mitigation measures to limit changes to groundwater quantity during Operations is provided in the Groundwater Technical Support Document (**Appendix H**). • The groundwater monitoring program is described in more detail in the Peatlands Technical Support Document (**Appendix I**). • Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction.	• Residual changes to caribou and moose habitat availability and distribution from changes to groundwater quantity.	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Local Study Area • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Probable • Significance: Not Significant • Uncertainty: Moderate • Direct / Indirect: Direct
• **Caribou and Moose**	• Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing	• Construction	• Wildlife Attractants—Attraction of wildlife to the Project site (for example, food waste, sewage, petroleum-based products, dust suppressants, explosive powder, site runoff ponds) may increase human-wildlife interactions and change predator-prey relationships, which can affect animal survival and reproduction.	• An Environmental Protection Plan will be developed and implemented that includes policies and actions anticipated to mitigate the attraction of wildlife to the Construction Disturbance Area, particularly near the temporary construction staging areas and temporary construction camps. • A Waste Management Plan will be developed and implemented that describe the appropriate management of solid, liquid and hazardous waste, including: – Construction-related garbage, debris, and surplus materials. – Hazardous materials such as used oil, filter and grease cartridges, lubrication containers. – Domestic garbage and camp waste (such as, food and grey water). Portable, secure, solid	• Residual changes to caribou and moose survival and reproduction from attractants	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Possible • Significance: Not Significant • Uncertainty: Low • Direct / Indirect: Direct

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				waste receptacles will be provided on work sites, temporary laydown areas and temporary construction camps and periodically emptied. • Construction staff will be educated about hazards of littering and feeding wildlife. A no littering policy will be implemented and enforced. • Feeding and harassment of wildlife on site will be prohibited. • De-icing salts will not be used on the unpaved Community Access Road during construction or operation. • Roadkill will be cleaned up during construction and operations following best management practices outlined by Ontario's Ministry of Transportation. • Collect domestic (for example, food) and industrial (for example, used oil and lubricants) waste and store temporarily in wildlife proof containers. Transport all waste offsite for recycling or disposal at a licensed disposal facility. • Potentially toxic materials that attract wildlife will be stored in secure areas inaccessible to wildlife (for example, buildings, storage areas surrounded by wildlife-proof fencing), and toxic materials will be monitored continuously when removed from storage until they are used or returned to storage to prevent wildlife accessing and ingesting the materials. • Empty chemical toilets on site regularly by a licensed sewage-handling owner / operator. • The method of domestic sewage disposal at temporary construction camps will be determined during detail design. Options may include holding tank systems with offsite disposal or onsite leaching beds designed in accordance with applicable codes and approvals. All required permits and authorizations will be acquired for construction and operation of these. Where subsurface sewage disposal systems are proposed, they will be designed in accordance with the Ontario Building Code for systems under 10,000 litres per day. For systems exceeding this threshold, approval under Section 53 of the Ontario *Water Resources Act* will be obtained. If required and when feasible, domestic wastewater will be removed by approved disposal trucks and disposed of at wastewater treatment plants with the authorization and capacity to accept this wastewater.		

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Wildlife Attractants—Attraction of wildlife to the Project site (for example, food waste, sewage, petroleum-based products, dust suppressants, explosive powder, site runoff ponds) may increase human-wildlife interactions and change predator-prey relationships, which can affect animal survival and reproduction.	• Roadkill, debris, and waste management as per Ministry of Transportation's Debris Control Maintenance Quality Standard (MQS-331) and Ministry of Transportation's Rest Area / Picnic Site Maintenance Best Practice (MBP-325).	• Residual changes to caribou and moose survival and reproduction from attractants	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Possible • Significance: Not Significant • Uncertainty: Low • Direct / Indirect: Direct
• **Caribou and Moose**	• Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Pits and quarries • Drilling / blasting / aggregate production	• Construction	• Blasting and associated fly rock—may result in injury or mortality to wildlife.	• A comprehensive list of mitigation measures to minimize effects from blasting during construction is provided in the Acoustic and Vibration Environment Technical Support Document (Appendix P). • An Environmental Protection Plan will be implemented that includes policies and actions for avoiding and minimizing the risks of blasting and blasting materials to wildlife, including ungulates. • Blasting work will be completed as quickly as possible to shorten the duration of disturbance. • Blasting will be suspended within 10 kilometres of known or potential caribou Category 1 areas during sensitive periods to minimize sensory disturbances (nursery areas: May 1 to July 14 very low tolerance, July 15 to September 15 low tolerance; winter use areas: December 1 to March 31; Ministry of the Environment, Conservation and Parks, 2025, 2013b). If timing windows cannot be adhered to, follow environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources. • Open excavations and blasting areas will be fenced off if left unsupervised to avoid injury and mortality of ungulates. • A buffer zone will be placed around the perimeter of blasting activities and surrounding forested habitat. Blasting will be prohibited if large mammals (such as, moose and / or caribou) are observed within 500 metres from the blasting location. Pre-blasting surveys will be developed in the Environmental Protection Plan and followed.	• No residual effect anticipated	• No residual effect anticipated

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Blasting and associated fly rock—may result in injury or mortality to wildlife.	• A comprehensive list of mitigation measures that will be implemented during Operations is provided in Acoustic and Vibration Environment Technical Support Document (Appendix P). • Blasting will be suspended within 10 kilometres of known or potential caribou Category 1 areas during sensitive periods to minimize sensory disturbances (nursery areas: May 1 to July 14 very low tolerance, July 15 to September 15 low tolerance; winter use areas: December 1 to March 31; Ministry of the Environment, Conservation and Parks, 2025, 2013b). If timing windows cannot be adhered to, follow environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources.	• No residual effect anticipated	• No residual effect anticipated
• **Caribou and Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary construction camps • Temporary access roads and trails • Right-of-way clearing and grubbing • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Chemical or hazardous material stored on the Project site, or spills—(for example, petroleum products, ammonium nitrate) on site or along access or haul roads can affect wildlife survival and reproduction.	• Adhere to federal and provincial regulations and guidelines regarding hazardous substance collection and storage, use and handling, and disposal and treatment, such as the *Transportation of Dangerous Goods Act* (Government of Canada, 1992), *Dangerous Goods Handling and Transportation Act* (Government of Ontario, 1990j), and the *Environmental Protection Act* (Government of Ontario, 1990e). • Mitigation measures described in the Surface Water Technical Support Document (**Appendix F**), Groundwater Technical Support Document (**Appendix H**), Physiography, Terrain, and Soils Technical Support Document (**Appendix N**), and Vegetation Technical Support Document (**Appendix J**) will be implemented to minimize effects from chemical and hazardous material spills in the ungulate effects assessment Local Study Area during construction.	• No residual effect anticipated	• No residual effect anticipated
• **Caribou and Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Chemical or hazardous material stored on the Project site, or spills—(for example, petroleum products, ammonium nitrate) on site or along access or haul roads can affect wildlife survival and reproduction.	• Mitigation measures described in the Surface Water Technical Support Document (**Appendix F**), Groundwater Technical Support Document (**Appendix H**), Physiography, Terrain, and Soils Technical Support Document (**Appendix N**), and Vegetation Technical Support Document (**Appendix J**) will be implemented to minimize effects from chemical and hazardous material spills in the ungulate effects assessment Local Study Area during Operations.	• No residual effect anticipated	• No residual effect anticipated

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
• **Boreal Caribou**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary access roads and trails • Temporary construction camps • Right-of-way clearing and grubbing • Pits and quarries • Temporary concrete batch plants • Drilling / blasting / aggregate production • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Habitat loss—The loss or alteration of vegetation and topography that may change habitat availability, use, and connectivity and influence ungulate abundance and distribution.	• Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction. • Locate the Project route in such a way that minimizes overlap with sensitive habitats to the extent feasible, including provincially identified Category 1 areas for caribou (nursery areas, winter use areas, travel corridors; Government of Ontario, 2013a) and potential new Category 1 areas identified in this Environmental Assessment / Impact Statement, areas which contain biophysical habitat attributes for caribou (Environment and Climate Change Canada, 2020), and significant wildlife habitat for moose. • The Project footprint is designed to minimize vegetation clearing and access road requirements to the extent feasible (for example, concentrate temporary activities spatially, retain habitat outside of scoped Construction Disturbance Area, restrict construction vehicle traffic to established access roads where feasible). • Limit to the extent feasible the construction of temporary (for example, access road) and permanent structures in wetlands or within 30 metres setback from a wetland. If construction cannot avoid wetlands and 30 metres setback, Ministry of Natural Resources will be notified as soon as possible prior to work starting. Work may will not be conducted unless approval is obtained from the appropriate regulatory agencies. • Construction of the Community Access Road will be conducted in phases (segment by segment) to limit the amount of disturbance at any particular time. • The Project construction schedule will avoid activities during the sensitive timing windows for caribou (in other words, May 1 to September 15 for nursery areas, December 1 to March 31 for winter use areas) within 10 kilometres of known and potential new Category 1 areas, to the extent practical. When activity restrictions cannot be followed, the Ministry of the Environment, Conservation and Parks will be engaged to determine alternative approaches. • Retain function, quality and connectivity of compatible habitat features (for example,	• Residual changes in habitat availability, use, connectivity, and abundance and distribution of caribou and moose due to habitat loss	• Context: Ecological • Direction: Negative • Magnitude: Caribou Regional Area: Low; Missisa range: low; Nipigon Range: Moderate; Ozhiski range: negligible; Pagwachuan: negligible • Geographic Extent: Local for habitat availability and survival and reproduction; Regional for habitat distribution (caribou movement and connectivity). • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Certain • Significance: Caribou Regional Study Area: Not significant; Missisa range: Not significant; Nipigon range: Significant; Ozhiski range: Not significant; Pagwachuan range: Not significant • Uncertainty: Low for habitat availability and survival and reproduction; High for habitat distribution (caribou movement and connectivity) • Direct / Indirect: Direct

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				vegetation, trees, wildlife trees, coarse woody debris) as much as possible, particularly in selective, environmentally sensitive areas, to the extent practical and where safe to do so (for example, using proper setbacks of key habitat features, avoid severe water fluctuations, avoid terrestrial islands, avoid mineral licks, avoid unburned areas within wildfire perimeters, avoid migratory pathways). • Limit clearing of riparian vegetation (within 30 metres of waterbodies) to the extent practical and to the requirement of the access road and alignment clearing width only. • Known sensitive ecological features will be clearly marked (for example, wetlands and significant wildlife habitat) with associated setbacks. Engage with applicable government agency (Ministry of the Environment, Conservation and Parks, Ministry of Natural Resources and Environment and Climate Change Canada) if sensitive ecological features are encountered or cannot be avoided. • Use construction practices which encourage the eventual natural recovery / growth of native species (for example, winter exploration programs on frozen ground with no ripping or grubbing soil). • Maintain or improve ungulate habitat by using techniques that accelerate revegetation (for example, minimize topsoil removal, preserve adequate substrate, leave surface vegetation root mat intact). • Where possible, schedule work activities in wet areas during frozen conditions. • Under non-frozen conditions and where regulatory approvals allow, install mats (for example, rig mats, swamp mats or access mats) to limit effects on waterbodies and wetlands, if warranted and surface conditions require. • A Vegetation Management Plan including measures to protect rare plants and rare vegetation communities will be developed and implemented by the owner / operator. In the event a rare plant species or a rare vegetation community are encountered unexpectedly, or cannot be avoided, the rare plant protection measures outlined in the Vegetation Management Plan will be implemented. • Erosion control practices (for example, contouring) will limit wind and water erosion on cover soil and overburden stockpiles (for		

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				example, vegetation, erosion mats) as well as will encourage regrowth of vegetation. • Prevent starting wildfires from Project activities (for example, have readily available fire extinguishers, firefighting equipment, water packs / pails, provide firefighting training to staff, keep equipment clean and in good condition, no smoking outside designated areas, prepare an Emergency Response Plan). • Use progressive restoration and adopt practices to facilitate conifer recovery (for example, elevate mulching drums) on site once temporary construction areas are no longer needed. The time interval between commencement and completion of any work that disturbs earth surfaces will be a maximum of 20 calendar days. Commencement of such work will be considered to have occurred when the original stabilizing ground cover has been removed, including grubbing, or has been covered with fill material. Completion of such work will be considered to have occurred when the cover material (seed and mulch, seed and erosion control blanket, sod, rip-rap) has been applied. Where the timing of the operation results in a conflict with the application requirements of the specified cover, the owner / operator will determine appropriate interim measures that afford temporary protection until such a time as final cover can be applied. • Avoid re-entry and disturbance of reclaimed temporary access areas through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). • Reclaim temporary access roads, construction camps, waterbody crossings and laydown areas at the end of construction. • An Environmental Protection Plan and a Cleanup and Reclamation Plan will be developed and implemented. Where necessary, seedling planting will occur to improve restoration success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified. Reclamation plans will be confirmed through engagement with Indigenous communities, the Ministry of Natural Resources and local foresters. Effectiveness of revegetation efforts		

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities. If required, adaptive management will be employed to modify or enhance any reclamation efforts. • Restore on site should consider maintaining or improving wildlife habitat. Consider planting native trees, preferably conifers, to accelerate revegetation of the access roads and other temporary disturbances (or progressive reclamation through project life cycle). • A comprehensive list of mitigation measures to control weeds during construction and operations of the Project is provided in the Vegetation Technical Support Document (**Appendix J**) and Peatlands Technical Support Document (**Appendix I**).		
• **Boreal Caribou**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Habitat loss—The loss or alteration of vegetation and topography that may change habitat availability, use, and connectivity and influence ungulate abundance and distribution.	• Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources will be followed during Operations. • Maintenance activities with high levels of disturbance will avoid the sensitive timing windows for caribou (May 1 to September 15 for nursery areas, December 1 to March 31 for winter use areas) in known and potential new Category 1 areas, to the extent practical. When activity restrictions cannot be followed, the Ministry of the Environment, Conservation and Parks will be engaged to determine alternative approaches. • Complete maintenance work as quickly as possible to shorten the duration of disturbance. • Ongoing use of inactive areas will be prevented through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). • Avoid re-entry and disturbance of reclaimed temporary access areas through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access).	• Residual changes in habitat availability, use, connectivity, and abundance and distribution of caribou and moose due to habitat loss	• Context: Ecological • Direction: Negative • Magnitude: Caribou Regional Study Area: low; Missia Range: low; Nipigon Range: moderate • Geographic Extent: Local for habitat availability and survival and reproduction; Regional for habitat distribution (caribou movement and connectivity). • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Certain • Significance: Caribou Regional Study Area: Not significant; Missisa range: Not significant; Nipigon range: Significant; Ozhiski range: Not significant; Pagwachuan range: Not significant • Uncertainty: Low for habitat availability and survival and reproduction; High for habitat distribution (caribou movement and connectivity) • Direct / Indirect: Direct

If construction cannot avoid wetlands and 30 metres setback, Ministry of Natural	• Residual changes in habitat connectivity and associated caribou and moose distribution and survival due to linear barriers	• Context: Ecological • Direction: Negative • Magnitude: High • Geographic Extent: Local for habitat availability; Regional to beyond regional for habitat distribution and survival and reproduction (habitat and population connectivity and animal movement). • Duration / Reversibility: Long term / Irreversible • Frequency: Continuous • Likelihood: Probable • Significance: Caribou Regional Study Area: Significant; Missisa range: Significant; Nipigon range: Significant; Ozhiski range: Significant; Pagwachuan range: Not significant • Uncertainty: High • Direct / Indirect: Direct

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				Resources will be notified as soon as possible prior to work starting. Work may will not be conducted unless approval is obtained from the appropriate regulatory agencies. • Concentrate activities spatially and temporally to minimize fragmentation and barriers to movement across the landscape. • Minimize elevation and slope of soil piles and berms to allow ungulates to have clear line of sight to adjacent habitat. • Along the Project right-of-way and the access roads, maintain gaps in road berms and snowbanks to facilitate wildlife crossing at drainages, wildlife trails, strategic crossing points informed by movement data and Indigenous Knowledge, or connected habitat patches so that ungulate movements across roads are not blocked. • Snowbanks will be limited as much as possible and to a height of less than 1.6 metres. • Snow clearing along the access roads will incorporate road pull-outs at regular intervals to provide refuge for wildlife moving along the Community Access Road corridor. • At watercourse crossings that occur within Category 1 caribou habitat and are on the north-south segment of the Preferred Route (in other words, multi-span bridges WA-11 and WA-15, and clear span bridge WA-18), and at watercourse crossings that occur within Category 1 habitat and on the east-west segment of the Preferred Route (in other words, multi-span bridges W-34 and W-35, and clear span bridges NW-11, NW-12, NW-13, NW-14, NW-15, NW15A, NW-16, NW 17, NW-18) modified bridge and bridge embankments will be designed to incorporate terrestrial pathways adjacent to the aquatic habitat and allow for ungulate passage, where feasible given land cover considerations. These design features include increasing the height of bridge to minimum 4 metres vertical clearance, using natural substrates on the bridge embankments and under the bridge, allow for an unobstructed line of sight on either side of the bridge, and clear and maintain the minimum width of right-of-way at bridge crossings. In other locations along the Community Access Road where frequent crossings of species at risk are anticipated [in other words, in caribou Category 1 habitat (**Figure 9.4-7** to **Figure**		

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				9.4-9) and moose high suitability habitats (**Figure 9.4-14**)], reduced speed limits will be implemented and wildlife-friendly road embankments with gentle slopes (in other words, gradual incline) and smooth crush material will be constructed to encourage safe crossing. Specific sites will be informed by caribou collar data, habitat modelling and Indigenous Knowledge • Traffic speeds during construction will be posted. Speeds will be determined by temporary access road conditions and the discretion of the constructing owner / operator. • Vehicular traffic will be confined to approved right-of-way, workspace and access roads or trails. • The time that road Construction materials are left on the ground will be minimized to limit physical barriers to movement. • No longer needed and prevent ongoing use of inactive areas through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). The time interval between commencement and completion of any work that disturbs earth surfaces will be a maximum of 20 calendar days. Commencement of such work will be considered to have occurred when the original stabilizing ground cover has been removed, including grubbing, or has been covered with fill material. Completion of such work will be considered to have occurred when the cover material (seed and mulch, seed and erosion control blanket, sod, rip-rap) has been applied. Where the timing of the operation results in a conflict with the application requirements of the specified cover, the owner / operator will determine appropriate interim measures that afford temporary protection until such a time as final cover can be applied.

• **Moose**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary access roads and trails • Temporary construction camps • Right-of-way clearing and grubbing • Pits and quarries • Temporary concrete batch plants • Drilling / blasting / aggregate production • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Pits and quarries will be rehabilitated (progressive and final rehabilitation) and surrendered in accordance with the *Aggregate Resources Act* • Decommissioning of temporary camps, roads / trails and staging areas	• Construction	• Habitat loss—The loss or alteration of vegetation and topography that may change habitat availability, use, and connectivity and influence ungulate abundance and distribution.	• Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, will be followed during construction. • Locate the Project route in such a way that minimizes overlap with sensitive habitats to the extent feasible, including provincially identified Category 1 areas for caribou (nursery areas, winter use areas, travel corridors; Government of Ontario, 2013), areas which contain biophysical habitat attributes for caribou (Environment and Climate Change Canada, 2020), and significant wildlife habitat for moose. • The Project footprint is designed to minimize vegetation clearing and access road requirements to the extent feasible (for example, concentrate temporary activities spatially, retain habitat outside of scoped Construction Disturbance Area, restrict construction vehicle traffic to established access roads where feasible). • Limit to the extent feasible the construction of temporary (for example, access roads) and permanent structures in wetlands or within a 30-metre setback from a wetland. If construction cannot avoid wetlands or the 30-metre setback, the Ministry of Natural Resources will be notified as soon as possible prior to work starting. Work may will not be conducted unless approval is obtained from the appropriate regulatory agencies.	• Residual changes in habitat availability, use, connectivity, and abundance and distribution of caribou and moose due to habitat loss	• Context: Ecological • Direction: Negative • Magnitude: Low • Geographic Extent: Local for habitat availability and survival and reproduction; Regional for habitat distribution (habitat connectivity and animal movement) • Duration / Reversibility: Long term / Irreversible (permanent) • Frequency: Continuous • Likelihood: Certain for habitat availability; Probable for habitat distribution (habitat connectivity and movement) and survival and reproduction • Significance: Not significant • Uncertainty: Low for habitat availability and survival and reproduction; Moderate for habitat distribution (habitat connectivity and animal movement) • Direct / Indirect: Direct

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				• Construction of the Community Access Road will be conducted in phases (segment by segment) to limit the amount of disturbance at any particular time. • The Construction schedule will avoid activities during the sensitive timing windows for caribou (May 1 to September 15 for nursery areas, December 1 to March 31 for winter use areas) in known and potential new Category 1 areas, to the extent practical. When activity restrictions cannot be followed, the Ministry of the Environment, Conservation and Parks will be engaged to determine alternative approaches. • Retain function, quality and connectivity of compatible habitat features (for example, vegetation, trees, wildlife trees, coarse woody debris) as much as possible, particularly in selective, environmentally sensitive areas, to the extent practical and where safe to do so (for example, using proper setbacks of key habitat features, avoid severe water fluctuations, avoid terrestrial islands, avoid mineral licks, avoid unburned areas within wildfire perimeters, avoid migratory pathways). • Limit clearing of riparian vegetation (within 30 metres of waterbodies) to the extent practical and to the requirement of the access road and alignment clearing width only. • Known sensitive ecological features will be clearly marked (for example, wetlands and significant wildlife habitat) with associated setbacks. Engage with applicable government agency (Ministry of the Environment, Conservation and Parks, Ministry of Natural Resources and Environment and Climate Change Canada) if sensitive ecological features are encountered or cannot be avoided. • Use construction practices which encourage the eventual natural recovery / growth of native species (for example, winter exploration programs on frozen ground with no ripping or grubbing soil). • Maintain or improve ungulate habitat by using techniques that accelerate revegetation (for example, minimize topsoil removal, preserve adequate substrate, leave surface vegetation root mat intact). • Where possible, schedule work activities in wet areas during frozen conditions.		

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				• Under non-frozen conditions and where regulatory approvals allow, install mats (for example, rig mats, swamp mats or access mats) to limit effects on waterbodies and wetlands, if warranted and surface conditions require. • A Vegetation Management Plan including measures to protect rare plants and rare vegetation communities will be developed and implemented by the owner / operator. In the event a rare plant species or a rare vegetation community are encountered unexpectedly, or cannot be avoided, the rare plant protection measures outlined in the Vegetation Management Plan will be implemented. • Erosion control practices (for example, contouring) will limit wind and water erosion on cover soil and overburden stockpiles (for example, vegetation, erosion mats) as well as will encourage regrowth of vegetation. • Prevent starting wildfires from Project activities (for example, have readily available fire extinguishers, firefighting equipment, water packs / pails, provide firefighting training to staff, keep equipment clean and in good condition, no smoking outside designated areas, prepare an Emergency Response Plan). • Use progressive restoration and adopt practices to facilitate conifer recovery (for example, elevate mulching drums) on site once temporary construction areas are no longer needed. • Avoid re-entry and disturbance of reclaimed temporary access areas through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). • Reclaim temporary access roads, construction camps, waterbody crossings and laydown areas at the end of construction. • An Environmental Protection Plan and a Cleanup and Reclamation Plan will be developed and implemented. Where necessary, seedling planting will occur to improve restoration success on areas of temporary disturbance (for example, temporary access roads, laydown areas, camps, and workspaces) where habitat enhancement is identified. Reclamation plans will be confirmed through engagement with Indigenous		

Valued Components	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effects	Characterization of Predicted Residual Effect and Determination of Significance
				communities, the Ministry of Natural Resources and local foresters. Effectiveness of revegetation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities. If required, adaptive management will be employed to modify or enhance any reclamation efforts. • Restore on site should consider maintaining or improving wildlife habitat. Consider planting native trees, preferably conifers, to accelerate revegetation of the access roads and other temporary disturbances (or progressive reclamation through project life cycle). • A comprehensive list of mitigation measures to control weeds during construction and operations is provided in the Vegetation Technical Support Document (Appendix J) and Peatlands Technical Support Document (Appendix I).		
• **Moose**	• Operate the Preferred Route • Maintain the Preferred Route	• Operations	• Habitat loss—The loss or alteration of vegetation and topography that may change habitat availability, use, and connectivity and influence ungulate abundance and distribution.	• Environmental approval conditions, permits, or authorizations issued for the Project, including those issued from Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources will be followed during Operations. • Maintenance activities with high levels of disturbance will avoid the sensitive timing windows for caribou (May 1 to September 15 for nursery areas, December 1 to March 31 for winter use areas) in known and potential new Category 1 areas, to the extent practical. When activity restrictions cannot be followed, the Ministry of the Environment, Conservation and Parks will be engaged to determine alternative approaches. • Complete maintenance work as quickly as possible to shorten the duration of disturbance. • Ongoing use of inactive areas will be prevented through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access). • Avoid re-entry and disturbance of reclaimed temporary access areas through combined use of physical control measures (rollback, remove of creek crossings, recontouring to surrounding topography, revegetation / reforesting and / or barriers at junctions with active access).	• Residual changes in habitat availability, use, connectivity, and abundance and distribution of caribou and moose due to habitat loss	• Context: Ecological • Direction: Negative • Magnitude: Low • Geographic Extent: Local for habitat availability and survival and reproduction; Regional for habitat distribution (caribou movement and connectivity). • Duration / Reversibility: Long term / Irreversible (permanent features such as the Community Access Road); Long term / Reversible (temporary features such as access roads, construction camps) • Frequency: Continuous • Likelihood: Certain for habitat availability; Probable for habitat distribution (habitat connectivity and movement) and survival and reproduction • Significance: Not significant • Uncertainty: Low for habitat availability and survival and reproduction; Moderate for habitat distribution (habitat connectivity and animal movement) • Direct / Indirect: Direct

				• Marten Falls First Nation continues to engage in discussions with the Province regarding the ownership and future operations of the Community Access Road. Access and ownership including gating security / ID system, will require further dialogue between the communities and the Province. • During Operations, the ongoing use of inactive areas by the public will be minimized through physical control measures such as rollback, removal of creek crossings, felling of timber across temporary access roads, recontouring to surrounding topography, revegetating / reforesting and / or barriers at junctions with active access. Progressive reinstatement and revegetation would be implemented as non-permanent features would be decommissioned and restored or revegetated naturally. • In the event of a mortality of a species at risk due to collisions with equipment or vehicles during construction and / or operations, the owner / operator and / or operator should report the incident to SAROntario@ontario.ca and the Natural Heritage Information Centre at NHICRequests@ontario.ca.		

9.4.6 Physiography, Terrain and Soils

9.4.6.1 Project-Environment Interactions

As a component of the effects assessment, the Project activities were reviewed to find potential environmental interactions. These interactions were then assessed for potential effect (**Table 9.4-15**).

Table 9.4-15: Project-Environment Interactions - Physiography, Terrain and Soils

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction**	• Clearing the right-of-way (for example remove and dispose of trees, shrubs, fallen timber, and surface litter, strip organic materials, grub) • Blasting rock (for example remove rock at quarries, and as required, at specific locations in association with road and bridge construction) • Constructing the Community Access Road (for example overburden excavation and removal, excavation of granular material at pits, remove unsuitable soil, place and compact rock and granular material, trim and shape the road, stockpiling of mineral soil and leaf litter [organic material], and soil handling and replacement from stockpiles at decommissioning) • Constructing bridges and installing culverts (for example surface water management and erosion control, dewatering of the watercourses to create ice bridges, alteration of natural drainage systems, watercourse bank grading to improve approaches if required) • Constructing, operating, and decommissioning temporary infrastructure (for example remove temporary culverts and bridges, remediate channels) • Mobilization of equipment, supplies, and personnel (for example haulage of materials, solid and liquid waste management, fuel storage, and hazardous materials handling, sewage and effluent treatment and water storage and effluent monitoring for temporary construction camps)	• Physiography, Terrain and Soils	• Quantity (area in hectares) and distribution of terrain units, which includes surficial materials, topography, and slope stability • Quantity (area in hectares) and distribution of soil map units • Soil quality (in other words, productivity, reclamation suitability)	• The overall effects due to Project-environment interaction during construction can be summarized as follows: • Changes to terrain quantity and distribution from Project activities • Changes to terrain quantity and distribution (esker landforms) from Project activities • Changes to terrain quantity and distribution (slope stability) from Project activities • Changes to soil quantity and distribution from Project activities • Changes to soil quality (compaction and admixing) from Project activities • Changes to soil quality from contamination due to potential leaks or spills of deleterious or hazardous substances from Project activities • Changes to soil quality from the transport and deposition of air contaminant emissions (for example potential acid inputs) and particulate matter (dust) from Project activities
• **Operations**	• Operate the Community Access Road • Maintain the Community Access Road	• Physiography, Terrain and Soils	• Quantity (area in hectares) and distribution of terrain units, which includes surficial materials, topography, and slope stability • Quantity (area in hectares) and distribution of soil map units • Soil quality (in other words, productivity, reclamation suitability)	• Changes to terrain quantity and distribution from Project activities • Changes to terrain quantity and distribution (esker landforms) from Project activities • Changes to terrain quantity and distribution (slope stability) from Project activities • Changes to soil quantity and distribution from Project activities • Changes to soil quality (compaction and admixing) from Project activities • Changes to soil quality from contamination due to potential leaks or spills of deleterious or hazardous substances from Project activities • Changes to soil quality from the transport and deposition of air contaminant emissions (for example potential acid inputs) and particulate matter (dust) from Project activities

9.4.6.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following physiography, terrain and soils definitions apply to the effects assessment.

Ecological and Social Context

Ecological context for physiography, terrain, and soils valued components considers resilience, adaptive capacity, status and trends, and applicable legislation and best management practices. The current and future sensitivity and resilience of the physiography, terrain, and soils valued component to change from the Community Access Road, are considered. The ecological context of the effect includes a discussion of the environmental consequences of the predicted effect.

Magnitude

For magnitude, environmental discipline-specific definitions are required and are provided in **Table 9.4-16**. Magnitude of effects are project-related and exclude variations due to climate change.

Table 9.4-16: Physiography, Terrain, and Soils Magnitude Definition

Magnitude Level (Rating)	Magnitude Level (Definition)
• Qualitative narrative or numeric quantification	• Change in measurement indicator is described by effect size (for example hectares of a terrain unit)

While most criteria were assigned categorical ratings, magnitude ratings for physiography, terrain, and soils were provided in specific terms (in other words, narrative or numeric quantification) in the residual effects assessment. Applying a category rating to a criterion such as magnitude might lead to confusion or misinterpretation of the effects assessment or result in the criterion not being easily categorized in a meaningful way. For example, characterizing magnitude solely using an ordinal scale (in other words, low, medium, or high) for physiography, terrain, and soils is often not appropriate as additional context is required to properly characterize the effects. Universal effect size boundaries, such as a 20 percent change in a terrain or soil map unit at the Local Study Area scale used to define a high magnitude effect, work poorly because these size boundaries fail to consider context. Depending on the ecological context, a 20 percent change from existing conditions in the study area may be required to cause a high magnitude effect on some units, whereas a 2 percent change in the study area may be sufficient to cause a high magnitude effect for other

units. When categorical definitions were used, magnitude was classified as negligible, low, medium, or high and supported by a reasoned narrative.

9.4.6.3 Residual Effects - Construction Phase

9.4.6.3.1 Changes to Terrain Quantity and Distribution

9.4.6.3.1.1 Potential Effects

The Project will have a direct effect on terrain in the Construction Disturbance Area during construction due to clearing, earth moving, excavation at pits and / or blasting at quarry sites and other road construction activities. Although excavation at pits and quarries is still anticipated as part of road maintenance activities during operations, for the purposes of the assessment it is assumed that all pit and quarry sites will reach their maximum footprint extent during construction.

Alteration of terrain conditions (in other words, quantity and distribution) within the Construction Disturbance Area may change surface expression, surficial material thickness, or associated soil drainage, and could potentially influence the ability of terrain and soil to support the establishment of plant species and vegetation communities and associated wildlife habitat and species. Indigenous Knowledge from Marten Falls First Nation noted generalized concerns related to the potential for overall landscape disturbances and how these changes might affect their usage of the land (Dillon, 2026a; Marten Falls First Nation, 2019). Marten Falls First Nation also noted that they are concerned about how development will affect their connection to the land, including concerns related to the effects of blasting on cultural / spiritual sites. In particular, community members have noted beliefs that the development will alter the natural landscape, thereby impacting the beauty, tranquility, silence, and special places of Marten Falls First Nation's traditional territory (Marten Falls First Nation, 2023).

9.4.6.3.1.2 Mitigation and Enhancement Measures

Mitigation measures that will be implemented during construction include:

- Limit the Project footprint (Construction Disturbance Area) to the extent practicable;
- Minimize areas of vegetation clearing and soil disturbance and optimize the use of existing cleared areas for Project activity (in other words, site clearing will be kept to a minimum within the Community Access Road right-of-way);

- Develop and implement a Project-specific Soil Management Plan (for example, soil stripping and handling recommendations, erosion and sediment control, reclamation procedures, best management practices and guidelines / policies);
- Minimize stripping and grading of terrain between the height of land (drainage divide) and the watercourse, or within 100 metres of a watercourse crossing, whichever is less, and limit to that required to address engineering issues and safety concerns, such as the removal of hazards. If stripping or grading occurs within such areas, the site will be stabilized;
- Regrade areas with erosional gullies to conform to the local landform to maintain drainage patterns during decommissioning of temporary infrastructure;
- Strip the overburden from bedrock quarry areas before blasting, or excavating and will be managed in accordance with the On-Site and Excess Soil Management Regulation under the Ontario *Environmental Protection Act*; and
- All pits and quarries will be rehabilitated during their operational lifetime and once extraction is finished as per the Ontario Ministry of Natural Resources *Aggregate Resources Act*.

9.4.6.3.1.3 Residual Effects

Reclamation and / or rehabilitation of temporary disturbances is predicted to reverse changes to temporarily disturbed terrain units to sustain productive soils, which would support the establishment and succession of vegetation communities with similar function to existing conditions ecosystems. Rehabilitation in reference to pits and quarries is defined as “the treatment of land from which aggregate has been excavated so that the use or condition of the land is restored to its former use or condition or is changed to another use or condition that is or will be compatible with the use of adjacent land” (Government of Ontario, 1990). The establishment of reclaimed terrain is predicted to occur through the decommissioning activities for temporary infrastructure at the end of construction. The terrain will be reclaimed by regrading the terrain to blend with existing topography and landforms. In a study conducted in central Alberta, Macyk (1986) suggested reconstructed soils are composites of the original soil units and the resultant soil properties are largely controlled by surficial material characteristics (terrain) and material handling procedures. Irreversible residual effects from the Project will remain in 84.6 percent of the Construction Disturbance Area, associated with the areas of permanent disturbance; this change will be brought forward into the Residual Effects Analysis.

Project activities and components would alter terrain conditions (in other words, quantity and distribution), which could subsequently adversely affect soil productivity and the

types of ecosystems that can be re-established on the landscape through reclamation. Project activities that would affect terrain quantity and distribution include land clearing and site preparation for infrastructure and facilities during construction, hauling and deposition of aggregate (for example, bedrock, sand, and gravel), and other materials during construction, and removal of infrastructure and facilities and associated reclamation and revegetation of non-permanent Project components through decommissioning and reclamation activities at the end of construction. As this residual effect is of negligible magnitude and certain to occur, the effect was carried forward into the cumulative effects assessment.

9.4.6.3.2 Changes to Terrain Quantity and Distribution (Esker Landforms)

9.4.6.3.2.1 Potential Effects

Project activities such as constructing the Community Access Road, sand and gravel pit creation and aggregate extraction have the potential to change or remove esker landforms during construction. Although excavation at pits and quarries is still anticipated as part of road maintenance activities during operations, for the purposes of the assessment it is assumed that all pit and quarry sites will reach their maximum footprint extent during construction. Because sand and gravel resources are rare in the effects assessment Local Study Area, the Construction Disturbance Area has been developed to target and include potential esker landforms as a potential aggregate (pit) resource. Indigenous Knowledge from Marten Falls First Nation and Aroland First Nation noted generalized concerns related to the potential for overall landscape disturbances and how these changes might affect their usage of the land (Dillon, 2026a; Dillon, 2026b; Marten Falls First Nation, 2019).

9.4.6.3.2.2 Mitigation and Enhancement Measures

Mitigation and enhancement measures that will be implemented to reduce changes to esker landforms during construction include:

- Minimize or avoid the use of eskers or similar geological features for aggregate resources by using bedrock quarries or other sand and gravel resources whenever possible;
- Confirm suitable aggregate material in ridged landforms prior to extraction; and
- All pits and quarries will be rehabilitated during their operational lifetime and once extraction is finished as per the Ontario Ministry of Natural Resources *Aggregate Resources Act*.

9.4.6.3.2.3 Residual Effects

Within the effects assessment Local Study Area, eleven polygons were mapped and identified as eskers. Of those eleven eskers, five have been identified as potential sand and gravel resources within the Construction Disturbance Area (SG-06, SG-19) and would be permanently disturbed to support road construction and operations. Approximately 45 percent of the esker features identified in the effects assessment Local Study Area will be permanently disturbed, and therefore this effect will be carried forward to the Residual Effects Assessment.

In the effects assessment Local Study Area, five of the eleven polygons (45 percent) identified as eskers would be permanently disturbed or destroyed as they are associated with sand and gravel resources within the Construction Disturbance Area (aggregate pits SG-06 and SG-19). Although the sand and gravel pits are required to be rehabilitated based on the Aggregate Resources act, it is not feasible to recreate an esker landform as the material forming the landform is to be used as an aggregate resource. Therefore, all five esker polygons are considered to be permanently disturbed or destroyed. Although sand and gravel resources are rare in the effects assessment Local Study Area, and knowledge from Marten Falls First Nation and Aroland First Nation noted generalized concerns related to the potential for overall landscape disturbances and how these changes might affect their usage of the land (Dillon, 2024a; Marten Falls First Nation, 2019), fewer than half of these landforms are predicted to be disturbed.

As this residual effect is of medium magnitude and certain to occur, the effect was carried forward into the cumulative effects assessment.

9.4.6.3.3 Changes to Quantity and Distribution of Terrain Units (Slope Stability)

9.4.6.3.3.1 Potential Effects

Project activities such as land clearing, site preparation, pit and quarry development, and earth works during construction have the potential to cause slope instability and increased probability of failure on slopes, especially those adjacent to watercourses or waterbodies.

9.4.6.3.3.2 Mitigation and Enhancement Measures

Mitigation and enhancement measures that will be implemented during construction to reduce changes to terrain stability include:

- Avoid or minimize the amount of area for construction facilities that are considered to have terrain that is either unstable or potentially unstable and design slopes for long-term stability. Stabilize slopes, if required;
- Have construction activities occur under frozen or dry conditions as much as possible;
- Avoid construction on highly saturated soil where practicable or use suitable ground equipment to avoid potentially increasing slope instability;
- Regrade areas with erosional gullies to conform to the local landform to maintain drainage patterns;
- Minimize any exposed mineral soil between the height of land (drainage divide) and the watercourse, or within 100 metres of a watercourse crossing, whichever is less, and limit to that required to address engineering issues and safety concerns, such as the removal of hazards. If stripping or grading occurs within such areas, the site will be left at a stable angle;
- Pit and quarry rehabilitation plans will address final slopes for pit and quarry areas to help maintain stable slopes suitable for reclamation;
- Use low road grades and proper drainage to reduce potential terrain instability, where feasible; and
- Implement progressive reclamation and revegetation of disturbed areas no longer required for construction.

9.4.6.3.3.3 Residual Effects

Terrain in the effects assessment Local Study Area is generally stable with only 64 hectares of terrain identified as being potentially unstable or unstable. Although surficial materials in large portions of the effects assessment Local Study Area have higher potential to be prone to failures, topography in the effects assessment Local Study Area is generally level, with very few areas of slopes steep enough to fail. The potentially unstable or unstable areas were identified almost exclusively adjacent to erosional slopes of watercourses, waterbodies, and peatlands (fens). The implementation of environmental design features, mitigation, and monitoring is expected to avoid adverse residual changes to slope stability potential increased probability of failures; and therefore, this effect was not carried forward to the residual effects assessment.

9.4.6.3.4 Changes to Quantity and Distribution of Soils

9.4.6.3.4.1 Potential Effects

The Project will have direct changes to soil in the Construction Disturbance Area during construction due to clearing, earth moving, pit and quarry development (including excavation and blasting), and other construction activities. Changes to soil conditions (in other words, quantity and distribution) within the Construction Disturbance Area may adversely affect the soils ability to sustain ecosystems. Project activities may affect soil quantity and distribution through an increase in potential soil loss through wind or water erosion, or an alteration of soil map unit distribution.

9.4.6.3.4.2 Mitigation and Enhancement Measures

Mitigation measures that will be implemented during construction to reduce changes to soil quantity and distribution include:

- Limit the Project footprint (Construction Disturbance Area) to the extent practicable;
- Minimize areas of vegetation clearing and soil disturbance and optimize the use of cleared area for Project activity (such as, site clearing will be kept to a minimum within the Community Access Road right-of-way);
- Develop and implement a Project-specific Soil Management Plan (for example, soil stripping and handling recommendations, erosion and sediment control (based on the Ontario Ministry of Transportation's Erosion and Sediment Control Guide), reclamation procedures, best management practices and guidelines / policies);
- Select erosion and sediment control products that correspond with the nature and duration of the Project as recommended in the Project-specific Soil Management Plan;
- Regularly inspect and maintain erosion and sediment control structures (for example, sediment fences, rip rap or other sediment control structures) during all Project phases and modify measures as necessary. If control measures are not functioning properly, no further work will occur until the problem is resolved;
- Limit duration of soil exposure; phase activities whenever possible, and restore disturbed areas as soon as possible (such as, implement appropriate erosion and sediment control, and progressive reclamation and revegetation of disturbed areas no longer required);
- Control potential erosion by utilizing an effective road design (including use of engineered culverts and bridges);
- Selectively cut vegetation and restrict clearing and grubbing within areas with steep slopes or soils prone to risk of erosion;

- Do not include mineral soil in the debris piles during clearing;
- Have construction activities occur under frozen or dry conditions as much as possible;
- Use clearing equipment appropriate to the nature of work being conducted that minimizes surface disturbance, soil compaction, and topsoil loss (for example, equipment with low ground pressure tracks or tires, blade shoes, and brushes), where feasible. For example, avoid using large machinery when hand tools or smaller scale machinery could be used;
- Regrade areas with vehicle ruts and erosion gullies to conform to the local landform to maintain drainage patterns;
- To the extent practicable, avoid work in sensitive areas (such as, erosive soils, wetland features, and fish habitats) during periods that may result in high flow volumes and / or increased erosion and sedimentation (such as, spring freshet) and help to confirm soil stockpiles are setback at least 100 metres from watercourses;
- Minimize stripping and grading of terrain between the height of land (drainage divide) and the watercourse, or within 100 metres of a watercourse crossing, whichever is less, and limit to that required to address engineering issues and safety concerns, such as the removal of hazards. If stripping or grading occurs within such areas, the site will be left at a stable angle;
- Use low road grades and proper drainage to reduce soil erosion, where feasible;
- Install and regularly maintain mitigation measures prior to the commencement of any site clearing, grubbing, excavation, filling, or grading works, prior to and after runoff events;
- Where soils are prone to wind erosion, apply tackifier, cover, and seed, apply water or pack the topsoil stockpiles and windrows with approved equipment, especially during periods of high erosion potential (such as, summer and fall);
- When practicable, consider pre-fabrication (such as, parts of structures) at an approved offsite location to minimize onsite construction effects;
- Minimize steepness and length of slopes of disturbed areas and stockpiled soils;
- Avoid placing soil stockpiles near waterbodies or drainage features (such as., a minimum distance of 100 metres from watercourses);
- All pits and quarries will be rehabilitated during their operational lifetime and once extraction is finished as per the Ontario Ministry of Natural Resources *Aggregate Resources Act*;

- Manage soil in accordance with the Best Management Practices for Aggregate Pit and Quarry Rehabilitation in Ontario (Madeh et al., 2021); and
- Manage any excess construction soil in accordance with the On-Site and Excess Soil Management Regulation under the Ontario *Environmental Protection Act*.

9.4.6.3.4.3 Residual Effects

Soils in the effects assessment Local Study Area are dominantly rated as having a low or moderate risk of wind erosion because of the finer soil textures noted, and dominantly have Very Low, Low, or Moderate susceptibility to water erosion because of the subdued landscape and lack of steep slopes. A higher proportion of soils with high wind erosion risk (approximately 11 percent more) were noted in the Construction Disturbance Area than in the effects assessment Local Study Area. This is due to the of the inclusion of sand and gravel resources which are associated with coarser textured soils prone to wind erosion. However, with environmental design features, mitigation, and monitoring, changes in soil distribution are anticipated to be minimized.

Reclamation and rehabilitation are predicted to reverse effects on temporarily disturbed soil map units and provide adequate material for the development of productive soils, which would support the establishment and succession of vegetation communities with similar function to natural ecosystems not influenced by the Project. Rehabilitation in reference to pits and quarries is defined as “the treatment of land from which aggregate has been excavated so that the use or condition of the land is restored to its former use or condition or is changed to another use or condition that is or will be compatible with the use of adjacent land” (Government of Ontario, 1990). The establishment of reclaimed soil in temporary components of the Project is predicted to occur well into operations, particularly for mature forest types. Irreversible residual effects from the Project will remain in 84.3 percent of the Construction Disturbance Area, and 3.4 percent of the effects assessment Local Study Area associated with the areas of permanent disturbance; this change will be brought forward into the Residual Effects Analysis.

The Project footprint would be limited to the extent practicable to minimize changes in quantity and distribution of soil units. Vegetation clearing and soil disturbance would also be limited to the minimum area required and work in areas containing soils sensitive to loss (such as, by erosion) would be scheduled during non-sensitive times of the year (such as, outside of spring freshet), to the extent practicable. Progressive reclamation and revegetation would be completed as facilities are removed and areas are no longer required for the Project to avoid prolonged soil exposure and potential soil loss. As this residual effect is of negligible magnitude and certain to occur, the effect was carried forward into the cumulative effects assessment.

9.4.6.3.5 Changes to Soil Quality from Compaction and Admixing

9.4.6.3.5.1 Potential Effects

For the effects assessment, existing soil quality has been described by categorizing soil based on its suitability for reclamation which takes chemical and physical characteristics of soil into consideration. These include pH, salinity, sodicity, base saturation, stoniness or coarse fragment content, texture, moisture content, and calcium carbonate equivalent. These characteristics typically change through the soil profile and require that during land clearing and site preparation, benefits of stripping the topsoil separately from the subsoil are considered. Site clearing, earth moving, excavation, pit and quarry development, and other construction activities can cause admixing and compaction which may change the quality of soil.

9.4.6.3.5.2 Mitigation and Enhancement Measures

Mitigation that will be implemented during construction to reduce changes to soil quality include:

- Limit the Project footprint (Construction Disturbance Area) to the extent practicable;
- Develop and implement a Project-specific Soil Management Plan (for example, soil stripping and handling recommendations, erosion and sediment control (based on the Ontario Ministry of Transportation's Erosion and Sediment Control Guide), reclamation procedures, best management practices and guidelines / policies);
- Use clearing equipment appropriate to the nature of work being conducted that minimizes surface disturbance, soil compaction, and topsoil loss (for example, equipment with low ground pressure tracks or tires, blade shoes, and brushes), where feasible. For example, avoid using large machinery when hand tools or smaller scale machinery could be used;
- Have construction activities occur under frozen or dry conditions as much as possible;
- Use low pressure or rubber tracked vehicles for the early phase of the construction season and only higher-pressure equipment when the ground surface is strong enough to prevent compaction and rutting;
- Avoid construction activities on highly saturated soil (primarily during or immediately after rain events or during freshet) where practicable or use suitable ground equipment to prevent unnecessary soil damage through rutting, for example. Crews should be prepared to stop work in these conditions;

- Regrade areas with vehicle ruts and erosion gullies to conform to the local landform to maintain drainage patterns; and
- De-compact subsoils, temporary access trails and soils damaged during wet weather.

9.4.6.3.5.3 Residual Effects

Soil compaction can occur during site clearing, contouring, and excavation if heavy equipment passes over soils that are sensitive to compaction. Generally, well-drained, coarse- and medium-textured soils (in other words, loams, sandy loam, loamy sand, loam) are less prone to compaction than fine-textured soils (in other words, silty clay loam, silty clay, clay loam, and clay). However, sensitivity to compaction can change based on soil moisture conditions (Lewis et al., 1989). Soils within the effects assessment Local Study Area generally have Low susceptibility to compaction; however, soils in level or low-lying areas that are under higher moisture conditions (for example, Gleysols) have a High susceptibility to compaction, and soils with moderately fine to very fine textures (for example, the L1, L4, M5 soil map units) are generally rated as having a Moderate susceptibility to compaction.

Reclamation and proper soil handling and management is predicted to reverse changes on temporarily disturbed soil map units and provide adequate material for the development of productive soils, which would support the establishment and succession of vegetation communities with similar function to natural ecosystems not influenced by the Project. The establishment of reclaimed soil in temporary components of the Project is predicted to occur well into operations, particularly for mature forest types.

Project activities could result in a measurable minor change to soil quality within the Construction Disturbance Area relative to existing conditions; however, the effect is expected to be localized and with the effective implementation of mitigation measures, no residual effects are predicted, and this effect was not carried forward to the Residual Effects Assessment.

9.4.6.4 Residual Effects – Operations Phase

9.4.6.4.1 Changes to Soil Quality from Contamination due to Potential Leaks or Spills of Deleterious or Hazardous Substances

9.4.6.4.1.1 Potential Effects

There is the potential for accidental spills of fuels and other materials resulting in the release of deleterious substances and soil contamination during operations. These can occur from malfunctions of equipment such as hydraulic and fluid leaks, spills during equipment or vehicle refuelling, or from vehicle accidents.

9.4.6.4.1.2 Mitigation and Enhancement Measures

Mitigation measures that will be implemented during operations to reduce changes to soil quality from contamination include:

- Develop and implement a Spill Prevention and Emergency Response Plan, in the event of a spill;
- Adhere to Standard Operating Procedures for fuel handling;
- Construction and operations machinery will arrive on site in a clean condition, free from leaks;
- Crews will always keep a spill response kit on site during the work;
- Contain and clean up spills immediately in accordance with provincial regulatory requirements and the Spill Prevention and Emergency Response Plan;
- Transport fuel and hazardous materials in approved containers in licensed vehicles; and
- Require crews using the Community Access Road to report spills to the Ontario Spills Action Centre at 1-800-268-6060.

Community members from Marten Falls First Nation proposed a number of mitigation measures related to pollution control that were outlined within the Marten Falls First Nation Indigenous Knowledge Land Use and Occupancy Study (Marten Falls First Nation, 2023) including:

- Provide and make sure holding bats are readily available, so there is less chance of spillage;
- Provide adequate lighting at fuelling stations and monitoring so that people clean up after any spills;
- Provide various pit stops along the Community Access Road where drivers can check their tanks and valves; and
- Provide barriers along the sides of bridges to prevent other chemicals from spilling into waterways beneath them.

9.4.6.4.1.3 Residual Effects

The wash-off of fluids from accidental spills and leaks may result in an increase to the concentrations of chemical constituents to soils. However, leaks, or spills are considered avoidable with good planning, adequate design, and proper emergency response. Further to this, the frequency, spatial extent and severity of accidental spills or leaks during operations of the Project are anticipated to be minimized with the effective implementation of the mitigation and enhancement measures. However, it is recognized that, even with

the best planning and the implementation of mitigation measures, the potential exists for accidents and malfunctions. As such, measurable changes (such as, residual effects) to soil quality in the form of increase to the concentrations of chemical constituents could occur in the event of the wash-off from accidental spills or leaks. This effect is carried forward to the residual effects assessment.

Accidental spills and leaks from pit and quarry aggregate extraction and processing, the transportation, storage, and handling of hazardous materials during the construction, and the operation of vehicles and equipment during construction and operations, could occur, and, if occurring in high enough volumes, could change the chemical constituents and affect soil quality. The likelihood of occurrence of the effect was assessed as possible (the effect may occur, but is not likely), given that the implementation of the detailed Spill Prevention and Emergency Response Plan, which will be developed with consideration for applicable regulations and guidelines for spill management and clean-up, is expected to minimize opportunities for the wash-off of spills and leaks from relevant Project activities to enter nearby waterbodies.

As this residual effect is of negligible magnitude, infrequent and possible to occur, the effect was not carried forward into the cumulative effects assessment.

9.4.6.4.2 Changes to Soil Quality from the Transportation and Deposition of Air Contaminant Emissions (for example, Potential Acid Inputs) and Particulate Matter (Dust)

9.4.6.4.2.1 Potential Effects

Deposition of air contaminant emissions associated with Project activities are expected to occur from the combustion of fossil fuels and emission of criteria air contaminants. Criteria air contaminants include particulate matter less than 2.5 micrometres and 10 micrometres in diameter, total suspended particulates, carbon monoxide, sulphur dioxide, and nitrogen dioxides.

Construction activities such as land clearing, site preparation, site traffic, blasting of rock, burning of non-hazardous waste materials (for example, food waste), and handling of rock and aggregate materials from pit and quarry operations would generate criteria air contaminant and fugitive dust emissions, which can contain constituents such as metals. Accumulation of dust (in other words, total suspended particulate deposition) and associated constituents, such as metals, may result in changes to the chemical content of soil within affected areas. Changes to the chemical content of soil can alter soil pH and affect soil productivity. Operations activities, such as the operation of sand and gravel pits and quarries are also anticipated to result in emission of criteria air

contaminants and fugitive dust through the operation of equipment, combustion of fossil fuels and excavation and blasting activities.

Acid deposition may have an adverse effect on waterbodies, vegetation, and cause soil nutrient imbalances. Depending on the local airshed (in other words, heavy industry sources), the buffering capacity of the ecosystem or vulnerability to acid deposition may change. The Project location is considered a pristine environment, where heavy anthropogenic sources of emissions are not present (Dillon, 2026b). Air particulate emissions can change soil quality by altering soil pH, nutrient content, and the composition of soil organisms (Rusek and Marshall 2000; Jung et al., 2011; Chen et al., 2017). Air particulates may also affect cation and anion exchange in soil, decomposition rate of organic matter, and nutrient cycling (John et al., 2009; Jung et al., 2011). Deposition of sulphur dioxide and nitrogen dioxides could lead to acidification of soils (Holowaychuck and Fessenden, 1987; Bobbink et al., 1998).

9.4.6.4.2.2 Mitigation and Enhancement Measures

Mitigation measures that will be implemented during construction and operations to reduce changes to soil from emissions and deposition include those listed in the Atmospheric Environment Technical Support Document (**Appendix S**).

9.4.6.4.2.3 Residual Effects

Project design and mitigation policies and procedures are anticipated to limit fugitive dust emissions from the Project. Several mitigation measures would be applied to minimize dust deposition, such as watering the access roads and pits and quarries during dry conditions and establishing and enforcing speed limits on access roads to reduce dust production. With the effective implementation of mitigation measures, no residual effects are predicted for operations, and this effect was not carried forward to the Residual Effects Assessment.

9.4.6.5 Summary of Residual Effects

Table 9.4-17 provides a summary of the potential effects for physiography, terrain and soils, mitigation measures, and residual effects. Detailed information is included in **Appendix N**.

Table 9.4-17: Summary of Residual Effects for Physiography, Terrain and Soils

Valued Component	Project Activities	Project Phase	Description of Project Environmental Interaction	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Physiography, Terrain, and Soils**	• Blasting rock (for example, remove rock at quarries, and as required, at specific locations in association with road and bridge construction) • Constructing the Community Access Road (for example, overburden excavation and removal, excavation of granular material at pits, remove unsuitable soil, place and compact rock and granular material, trim and shape the road, stockpiling of mineral soil and leaf litter [organic material], and soil handling and replacement from stockpiles at decommissioning) • Constructing bridges and installing culverts (for example, surface water management and erosion control, dewatering of the watercourses to create ice bridges, alteration of natural drainage systems, watercourse bank grading to improve approaches if required) • Constructing, operating, and decommissioning temporary infrastructure (for example, remove temporary culverts and bridges, remediate channels)	• Construction	• Changes to terrain quantity / distribution from Project activities	• Limit the Project footprint (Construction Disturbance Area) to the extent practicable; • Minimize areas of vegetation clearing and soil disturbance and optimize the use of existing cleared areas for Project activity (in other words, site clearing will be kept to a minimum within the Community Access Road right-of-way); • Develop and implement a Project-specific Soil Management Plan (for example, soil stripping and handling recommendations, erosion and sediment control (based on the Ontario Ministry of Transportation's Erosion and Sediment Control Guide), reclamation procedures, best management practices and guidelines / policies); • Minimize stripping and grading of terrain between the height of land (drainage divide) and the watercourse, or within 100 metres of a watercourse crossing, whichever is less, and will be limited to that required to address engineering issues and safety concerns, such as the removal of hazards. If stripping or grading occurs within such areas, the site will be stabilized; • Regrade areas with erosional gullies to conform to the local landform to maintain drainage patterns during decommissioning of temporary infrastructure; • Strip the overburden from bedrock quarry areas before blasting or excavating and manage in accordance with the On-Site and Excess Soil Management Regulation, under the *Environmental Protection Act* (Government of Ontario, 1990e); and • All pits and quarries will be rehabilitated during their operational lifetime and once extraction is finished as per the *Aggregate Resources Act* (Government of Ontario, 1990b).	• Residual change to terrain quantity / distribution from Construction	• Context: Ecological • Direction: Negative • Magnitude: Negligible • Geographic Extent: Construction Disturbance Area • Duration: Long term for natural terrain units covered by permanent features (for example, Community Access Road); Medium-term for temporarily disturbed (reclaimed) terrain unit • Frequency: Infrequent • Reversibility: Irreversible: natural terrain map units covered by permanent features (for example, Community Access Road) • Likelihood: Certain • Uncertainty: Moderate • Direct / Indirect: Direct
• **Physiography, Terrain, and Soils**	• Constructing the Community Access Road (for example, overburden excavation and removal, excavation of granular material at pits, remove unsuitable soil, place and compact rock and granular material, trim and shape the road, stockpiling of mineral soil and leaf litter [organic material], and soil handling and replacement from stockpiles at decommissioning)	• Construction	• Changes to terrain quantity and distribution (esker landforms) from Project activities	• Minimize or avoid the use of eskers or similar geological features for aggregate resources by using bedrock quarries or other sand and gravel resources whenever possible; • Confirm suitable aggregate material in ridged landforms prior to extraction; and • All pits and quarries will be rehabilitated during their operational lifetime and once extraction is finished as per the *Aggregate Resources Act* (Government of Ontario, 1990b).	• Residual change to esker landforms from Construction	• Context: Ecological • Direction: Negative • Magnitude: Medium • Geographic Extent: Construction Disturbance Area • Duration: Long term • Frequency: Infrequent • Reversibility: Irreversible • Likelihood: Certain • Uncertainty: Moderate • Direct / Indirect: Direct

Footnotes: (a) Includes general maintenance activities (for example, grading, erosion control, excavation at pits / quarries and processing aggregate, dust suppression), seasonal maintenance activities (for example, clear vegetation on road shoulders, snow clearing and bridge and culvert maintenance, ditch maintenance), and special maintenance activities (for example, slope failures and road settlement / break-up).

- Various mitigation and enhancement measures have been included from the Community Access Road Preferred Route Selection and Preliminary Environmental Work Project Proposal (Marten Falls First Nation, 2017b).

9.4.7 Assessment of Significance of Land Disciplines

The assessment of significance of residual effects of the Community Access Road is informed by the interaction between the significance factors, with magnitude and geographic extent being the most important factors. Consideration is also given to context, which includes ecological context (in other words, the sensitivity and resilience of the valued components), and social context (in other words, concerns of Indigenous communities, interested agencies, groups and individuals raised during consultation and engagement and through review comments on the Environmental Assessment reports). Implementation of proven mitigation measures is expected to aid in the avoidance or reduction of the magnitude, geographic extent, and / or duration of residual effects on vegetation, wildlife, birds, ungulates and physiography, terrain and soils.

9.4.7.1 Determination of Significance

Using the overall residual effects characteristics for each discipline, each of the potential residual effects was assigned a significance level as a means of ranking the potential effects on the surface water quantity, surface water quality, and sediment quality. The significance levels are defined as:

- Significant**:** residual effects were considered to be significant if the majority of the residual effects characteristics were assessed as high in magnitude and long-term or permanent in duration, at any geographic extent, or they represented a management concern; and
- Not Significant: residual effects were considered not significant if they demonstrated any other combination.

9.4.7.2 Vegetation

The magnitude of the predicted residual effects on vegetation valued components is either negligible or low in magnitude and range from confined to the Construction Disturbance Area to local in geographic extent.

Residual effects on vegetation valued components were considered not significant as the residual effects were assessed negligible, low or medium in magnitude, and they do not represent a substantial concern for the long-term viability of vegetation valued components. There is the potential for management concerns through an increased public access leading to the spread of invasive species, increased risk of human-ignited wildlife and increased pressure on timber and Traditional Use Plant harvest, however these risks are minor and manageable.

Based on the weight of evidence from the analysis, uncertainty in effects predictions, specifically those associated with the “floating road” approach to construction and operation, and application of the precautionary approach, Project-related changes in the availability, distribution, composition, and function of Wetland Ecosystems could occur. Specifically, those changes to Wetland Ecosystems associated with groundwater quantity and quality were assessed as significant. As a result, the combined residual effects from the Project on Wetland Ecosystems are predicted to be significant.

Overall, the remaining vegetation valued components are expected to remain to be self-sustaining and ecologically effective, and therefore, the predicted residual effects on all vegetation valued components are assessed as not significant.

Overall, there is a moderate to high degree of confidence in the predictions related to the changes to vegetation valued components. Mitigation measures and best management practices would be implemented to reduce effects on the vegetation valued components and there is a high level of confidence in the mitigation measures and best management practices as these are routinely and effectively implemented across Canada.

Overall, confidence levels were considered to be moderate because there were existing conditions data for the effects assessment Local Study Area, the project-related effects are mostly understood, and the level of certainty associated with the effectiveness of proposed mitigations is low to high.

9.4.7.3 Wildlife

9.4.7.3.1 Bats (Little Brown Myotis and Northern Myotis)

The magnitude of the predicted residual effects on little brown myotis and northern myotis are of negligible to low magnitude and vary from being confined to the effects assessment Construction Disturbance Area to the wildlife effects assessment Local Study Area in geographic extent.

Residual effects on the bat valued component were considered not significant as the residual effects were assessed negligible to low in magnitude and they do not represent a substantial risk to bat populations in the effect assessment Regional Study Area.

Overall, the regional little brown myotis and northern myotis populations are expected to remain self-sustaining and ecologically effective in the residual effects assessment (in other words, there is no predicted change in the assessment endpoints). The anticipated changes to bat habitat availability, distribution, and survival and reproduction from the Community Access Road are expected to remain within the resilience and

adaptability limits of the regional populations. The residual effects from the Community Access Road on little brown myotis and northern myotis are therefore considered not significant.

9.4.7.3.2 Furbearers (Wolverine)

The magnitude of the predicted residual effects on wolverine is of negligible to moderate magnitude, short-term to permanent (irreversible) and vary from being confined to the effects assessment Construction Disturbance Area to the wolverine effects assessment Local Study Area in geographic extent. There is uncertainty about how wolverines will respond to the Community Access Road once constructed. It has the potential impact their distribution or connectivity at a regional level.

The Community Access Road occurs near the transition from boreal shield ecozone to the Hudson Bay Lowlands. Ray et. al. (2018), demonstrated that wolverine probability of occupancy declines in the Hudson Bay Lowlands compared to the boreal shield ecozone. While the limitations to wolverine occupancy in the Hudson Bay Lowland ecozone is not fully understood, it is speculated that it could be due to a lack of suitable resources (for example prey species) (Ray et. al. 2018). A large portion of the Regional Study Area lies within the Hudson Bay Lowland ecozone. The female wolverines displaced from boreal habitat by the Community Access Road may not be successful in establishing territories to the north and east of the Community Access Road. Therefore, there is a risk of reduced reproductive success in the females that inhabit home ranges that overlap with the Community Access Road which may represent a risk to the low-density wolverine population in the effect assessment Regional Study Area.

There is high uncertainty regarding the number of wolverine mortalities that may be caused by collisions with vehicles from the Community Access Road. Given that there are no existing permanent roads present in the effect assessment Regional Study Area, the wolverine that inhabit this area will be naive to the risk of road mortality. Wolverine are considered a threatened population in Ontario, whose populations are declining, and as such they will be sensitive to changes in survival and reproduction from an additional mortality source. Compounded by wolverines' low reproductive rate, and the low population density in the Regional Study Area, the mortality of a small number of reproductive females would have a negative effect on the regional population.

The residual effect from habitat loss and alteration and collisions with vehicles were predicted to have a moderate magnitude of effect on wolverines. Due to the high level of uncertainty (in other words, low prediction confidence) about how wolverines will respond to the Community Access Road once constructed and in the ability to avoid or mitigate the magnitude of these effects on the regional wolverine population, a

precautionary approach was applied, and it is anticipated that the Project effects may be significant to the sustainability of the population in the effect assessment Regional Study Area**.**

Overall, if the reproductive success of a few female wolverines in this low-density, low-reproductive-rate population is affected, the regional wolverine population may not remain self-sustaining and ecologically effective in the residual effects assessment (in other words, there is a predicted change in the assessment endpoints). The anticipated changes to wolverine habitat availability, distribution, and survival and reproduction from the Community Access Road may not remain within the resilience and adaptability limits of the regional population.

9.4.7.3.3 Furbearers (American Marten)

Predicted residual effects on American martens are of negligible to low magnitude and are short-term to permanent (irreversible) in duration and vary from being confined to the effects assessment Construction Disturbance Area to the wildlife effects assessment Local Study Area in geographic extent.

Residual effects on American marten were considered not significant as the residual effects were assessed to be negligible to low in magnitude and do not represent a substantial risk to marten populations in the effect assessment Regional Study Area.

Overall, American marten populations are expected to remain ecologically functional and self-sustaining in the residual effects assessment and there is no predicted change in the assessment endpoints. The anticipated changes to American marten habitat availability, distribution, and survival and reproduction from the Community Access Road are expected to remain within the resilience and adaptability limits of the regional populations.

9.4.7.3.4 Furbearers (Beaver)

Predicted residual effects on beavers are of negligible to low magnitude and are short-term to permanent (irreversible) in duration and vary from being confined to the effects assessment Construction Disturbance Area to the wildlife effects assessment Local Study Area in geographic extent.

Residual effects on beaver were considered not significant as the residual effects were assessed to be negligible to low in magnitude and do not represent a substantial risk to marten populations in the effect assessment Regional Study Area.

Overall, beaver populations are expected to remain ecologically functional and self-sustaining in the residual effects assessment and there is no predicted change in the assessment endpoints. The anticipated changes to beaver habitat availability, distribution, and survival and reproduction from the Community Access Road are expected to remain within the resilience and adaptability limits of the regional populations.

9.4.7.3.5 Reptiles and Amphibians

The magnitude of the predicted residual effects on reptiles and amphibian is of negligible to low magnitude, short-term to permanent (irreversible) and vary from being confined to the effects assessment Construction Disturbance Area to the wildlife effects assessment Local Study Area in geographic extent.

Residual effects on the reptiles and amphibians valued component were considered not significant as the residual effects were assessed negligible to low in magnitude and they do not represent a substantial risk to reptile and amphibian populations in the wildlife effect assessment Regional Study Area.

Overall, the regional reptile and amphibian populations are expected to remain self-sustaining and ecologically effective in the residual effects assessment (in other words, there is no predicted change in the assessment endpoints). The anticipated changes to reptile and amphibian habitat availability, distribution, and survival and reproduction from the Community Access Road are expected to remain within the resilience and adaptability limits of the regional populations. The residual effects from the Community Access Road on reptiles and amphibians are therefore considered not significant assuming the mitigation measures, including sub-surface eco-passages at strategic locations such as culverts are implemented.

9.4.7.3.6 Pollinating Insects

The magnitude of the predicted residual effects on pollinating insects is of negligible magnitude, short-term to permanent (irreversible) and vary from being confined to the effects assessment Construction Disturbance Area to the wildlife effects assessment Local Study Area in geographic extent.

Residual effects on the pollinating insect valued component were considered not significant, as the residual effects were assessed negligible in magnitude, and they do not represent a substantial risk to insect populations in the effect assessment Regional Study Area.

Overall, the regional pollinating insect populations are expected to remain self-sustaining and ecologically effective in the residual effects assessment (in other words, there is no predicted change in the assessment endpoints). The anticipated changes to pollinating insect habitat availability, distribution, and survival and reproduction from the Community Access Road are expected to remain within the resilience and adaptability limits of the regional population. The residual effects from the Community Access Road on pollinating insects are therefore considered not significant.

9.4.7.4 Birds

9.4.7.4.1 All Bird Valued Components

Predicted residual effects on all bird valued components are negative but negligible in magnitude, unlikely to possible to occur (except effects from changes to groundwater quantity and dust emissions on bird habitat availability and distribution, which are probable or certain), and ranging from confined to the effects assessment Construction Disturbance Area (for example incidental take) to confined to the Effects Regional Study Area (for example increased public access).

Bird valued components are predicted to remain self-sustaining and ecologically effective with the implementation of the Community Access Road. Overall, the anticipated changes to bird valued component habitat availability, distribution, and survival and reproduction from the Community Access Road are expected to remain within the resilience and adaptability limits of the regional populations. Effects from soil contamination from introduction and spread of invasive plants, emissions of criteria air contaminants, changes to erosion and sedimentation, changes to groundwater quantity, dust deposition, increased public access, incidental take, collisions with vehicles and equipment, and wildlife attractants on bird valued components are therefore predicted to be not significant.

9.4.7.4.2 Individual Birds

Information on individual bird species assessed can be found in Birds Technical Support Document (**Appendix L**). The following bird species were assessed:

- Forest Birds: Red-eyed Vireo, Oven bird, Dark-eyed Junco
- Raptors: Osprey, Boreal Owl
- Shorebirds: Wilson’s Snipe
- Waterfowl and Waterbirds: Mallard
- Bog / Fen Birds and Other Wetland Birds: Palm Warbler, Common Yellowthroat, Northern Waterthrush, Sora

- Species at Risk Birds: Canada Warbler, Evening Grosbeak, Chimney Swift, Bank Swallow, Barn Swallow, Common Nighthawk, Eastern Whip-poor-will, Eastern Wood-pewee, Olive-sided Flycatcher, Bald Eagle, Peregrine Falcon, Short-eared Owl, Black Tern, Lesser Yellowlegs, Rusty Blackbird, Yellow Rail

Predicted residual effects from habitat loss and sensory disturbance on bird habitat availability, distribution, and survival and reproduction are of low magnitude and are confined to the effects assessment Construction Disturbance Area or the effects assessment Local Study Area. Effects are certain or probable and are mostly irreversible (long-term).

Birds is predicted to remain self-sustaining and ecologically effective with the implementation of the Community Access Road. Overall, the anticipated changes to bird habitat availability, distribution, and survival and reproduction from the Community Access Road are expected to remain within the resilience and adaptability limits of the regional population. The residual effects from the Community Access Road for each individual bird species are therefore considered not significant.

9.4.7.5 Ungulates

9.4.7.5.1 Boreal Caribou

The predicted residual effects associated with each Community Access Road - environment interaction on Boreal caribou habitat availability, distribution and survival and reproduction vary from negligible to high magnitude, long-term in duration and a geographic scope that extends from the effects assessment Construction Disturbance Area to beyond the caribou effects assessment Regional Study Area. Residual effects on caribou due to sensory disturbance, increased predator access, increase in public access, collisions with vehicles and equipment, changes in groundwater, and fugitive dust emissions were determined to be not significant (**Table 9.4-14**). In contrast, residual effects on caribou from habitat loss and alteration and linear barriers were determined to be significant and varied among caribou ecotypes and ranges**.**

Caribou have large home ranges with specific habitat needs in different seasons and have demonstrated negative population-level responses to anthropogenic disturbances throughout their Canadian distribution. The Nipigon range is currently below the established threshold of 65 percent undisturbed habitat that is considered necessary to support a self-sustaining population, while the Missisa, Ozhiski and Pagwachuan ranges are above the threshold and predicted to be likely self-sustaining based on availability of critical habitat. Despite the availability of undisturbed habitat, there is uncertainty about the population trends in the Missisa, Ozhiski and Pagwachuan

ranges, which vary from declining to stable in federal and provincial assessments. Research conducted in northern Saskatchewan, where there is a similar natural disturbance regime and low net primary productivity as in the Missisa and Ozhiski ranges, found that caribou were resilient to fire disturbance (McLoughlin et al., 2019) and natural disturbance was not strongly linked to population growth of caribou (Neufeld et al., 2021). In the Missisa and Ozhiski ranges, the connection between a large amount of undisturbed habitat and a declining population trend leads to uncertainty in the resiliency of the populations in the exiting environment. Due to this uncertainty and following the precautionary approach, the confidence in the predicted potential effects ranged from low to high.

With the addition of the Community Access Road, the availability of habitat for caribou is expected to remain less than the threshold of 65 percent undisturbed habitat to maintain a self-sustaining population in the Nipigon range. The small incremental increase in habitat disturbance from the Community Access Road (3,951 hectares, which represents a 0.3 percent increase in anthropogenic disturbance in the range relative to existing conditions) will contribute to the existing significant effect of habitat loss and alteration in the Nipigon range. However, the loss of habitat is predicted to have little to no influence on survival and reproduction at the population level. The availability of habitat for caribou in the Missisa, Ozhiski and Pagwachuan ranges will remain above the threshold of 65 percent undisturbed, and the effect of habitat loss associated with the addition of the Community Access Road is predicted to be not significant on caribou in those ranges or the caribou effects assessment Regional Study Area.

A conservative approach was applied to the determination of significance for linear barrier effects on caribou mostly because this assessment was primarily informed by 2 years of recent collar data for caribou that interact with the ungulate effects assessment Local Study Area. Two years of data is not long relative to the longevity of caribou and acquiring confident knowledge of movement patterns. Previous collar data and federal and provincial assessments were also used to inform potential effects but were over 10 years old. Caribou collared for this Community Access Road and in previous research in northern Ontario have demonstrated behavioural plasticity in ecotypes and their movements between habitats. Other studies have detected variation in the responses of caribou to linear developments from strong avoidance to degrees of habituation and adaptive capacity to travel across roads. These variations in migratory movements and behavioural responses to linear features influence the confidence in predicting effects from the Community Access Road on the seasonal movement of eastern migratory caribou and connectivity between populations (or ranges) within and beyond the caribou effects assessment Regional Study Area (Nipigon, Missisa, Ozhiski, Pagwachuan ranges).

Given the minimal amount of anthropogenic disturbance in the ungulate effects assessment Local Study Area and in the Missisa and Ozshiki ranges, it is anticipated that naive caribou may exhibit strong avoidance behaviours during construction and operations of the Community Access Road. This may be particularly the case for more sedentary caribou with home ranges that overlap the Community Access Road. Over time, caribou may adapt and perceive the Community Access Road as a semi-permeable barrier to seasonal movements between important habitats or ranges. Alternatively, the Community Access Road may disrupt seasonal movements across ranges and connectivity between populations, which may have demographic consequences and lead to permanent changes in survival and reproduction. Due to these uncertainties and following the precautionary approach, the magnitude of the residual effect from linear barriers was assessed as high and determined to be significant.

Based on the weight of evidence, uncertainty in effects predictions and application of the precautionary approach, project-related changes in habitat availability and distribution and survival and reproduction could approach or extend beyond the resilience capabilities of one or more caribou population(s) overlapping the caribou effects assessment Regional Study Area. As a result, the combined residual effects from the Community Access Road on caribou and caribou habitat are determined to have a significant influence on self-sustaining and ecologically effective caribou populations.

9.4.7.5.2 Moose

The predicted residual effects associated with each Project-environment interaction on moose and moose habitat vary from negligible to high magnitude, short-term (reversible) to long-term (irreversible) duration, and from the effects assessment Construction Disturbance Area to the moose effects assessment Regional Study Area. Given the uncertainty in the potential increases in non-Indigenous and Indigenous moose harvest and the limited data on current Indigenous harvest levels, it was precautionarily assumed that the effects of increases in public access during Operations of the Project could reach unsustainable levels and lead to decreased resilience and maintenance of the self-sustaining and ecologically effective regional moose population. As such, residual effects on moose from increase in public access during Operations are precautionarily considered significant.

All other Project interactions are not predicted to significantly affect the ability of the regional moose population to remain self-sustaining and ecologically effective (in other words, there is no predicted change in the assessment endpoints). As such, all other Project interactions are considered not significant.

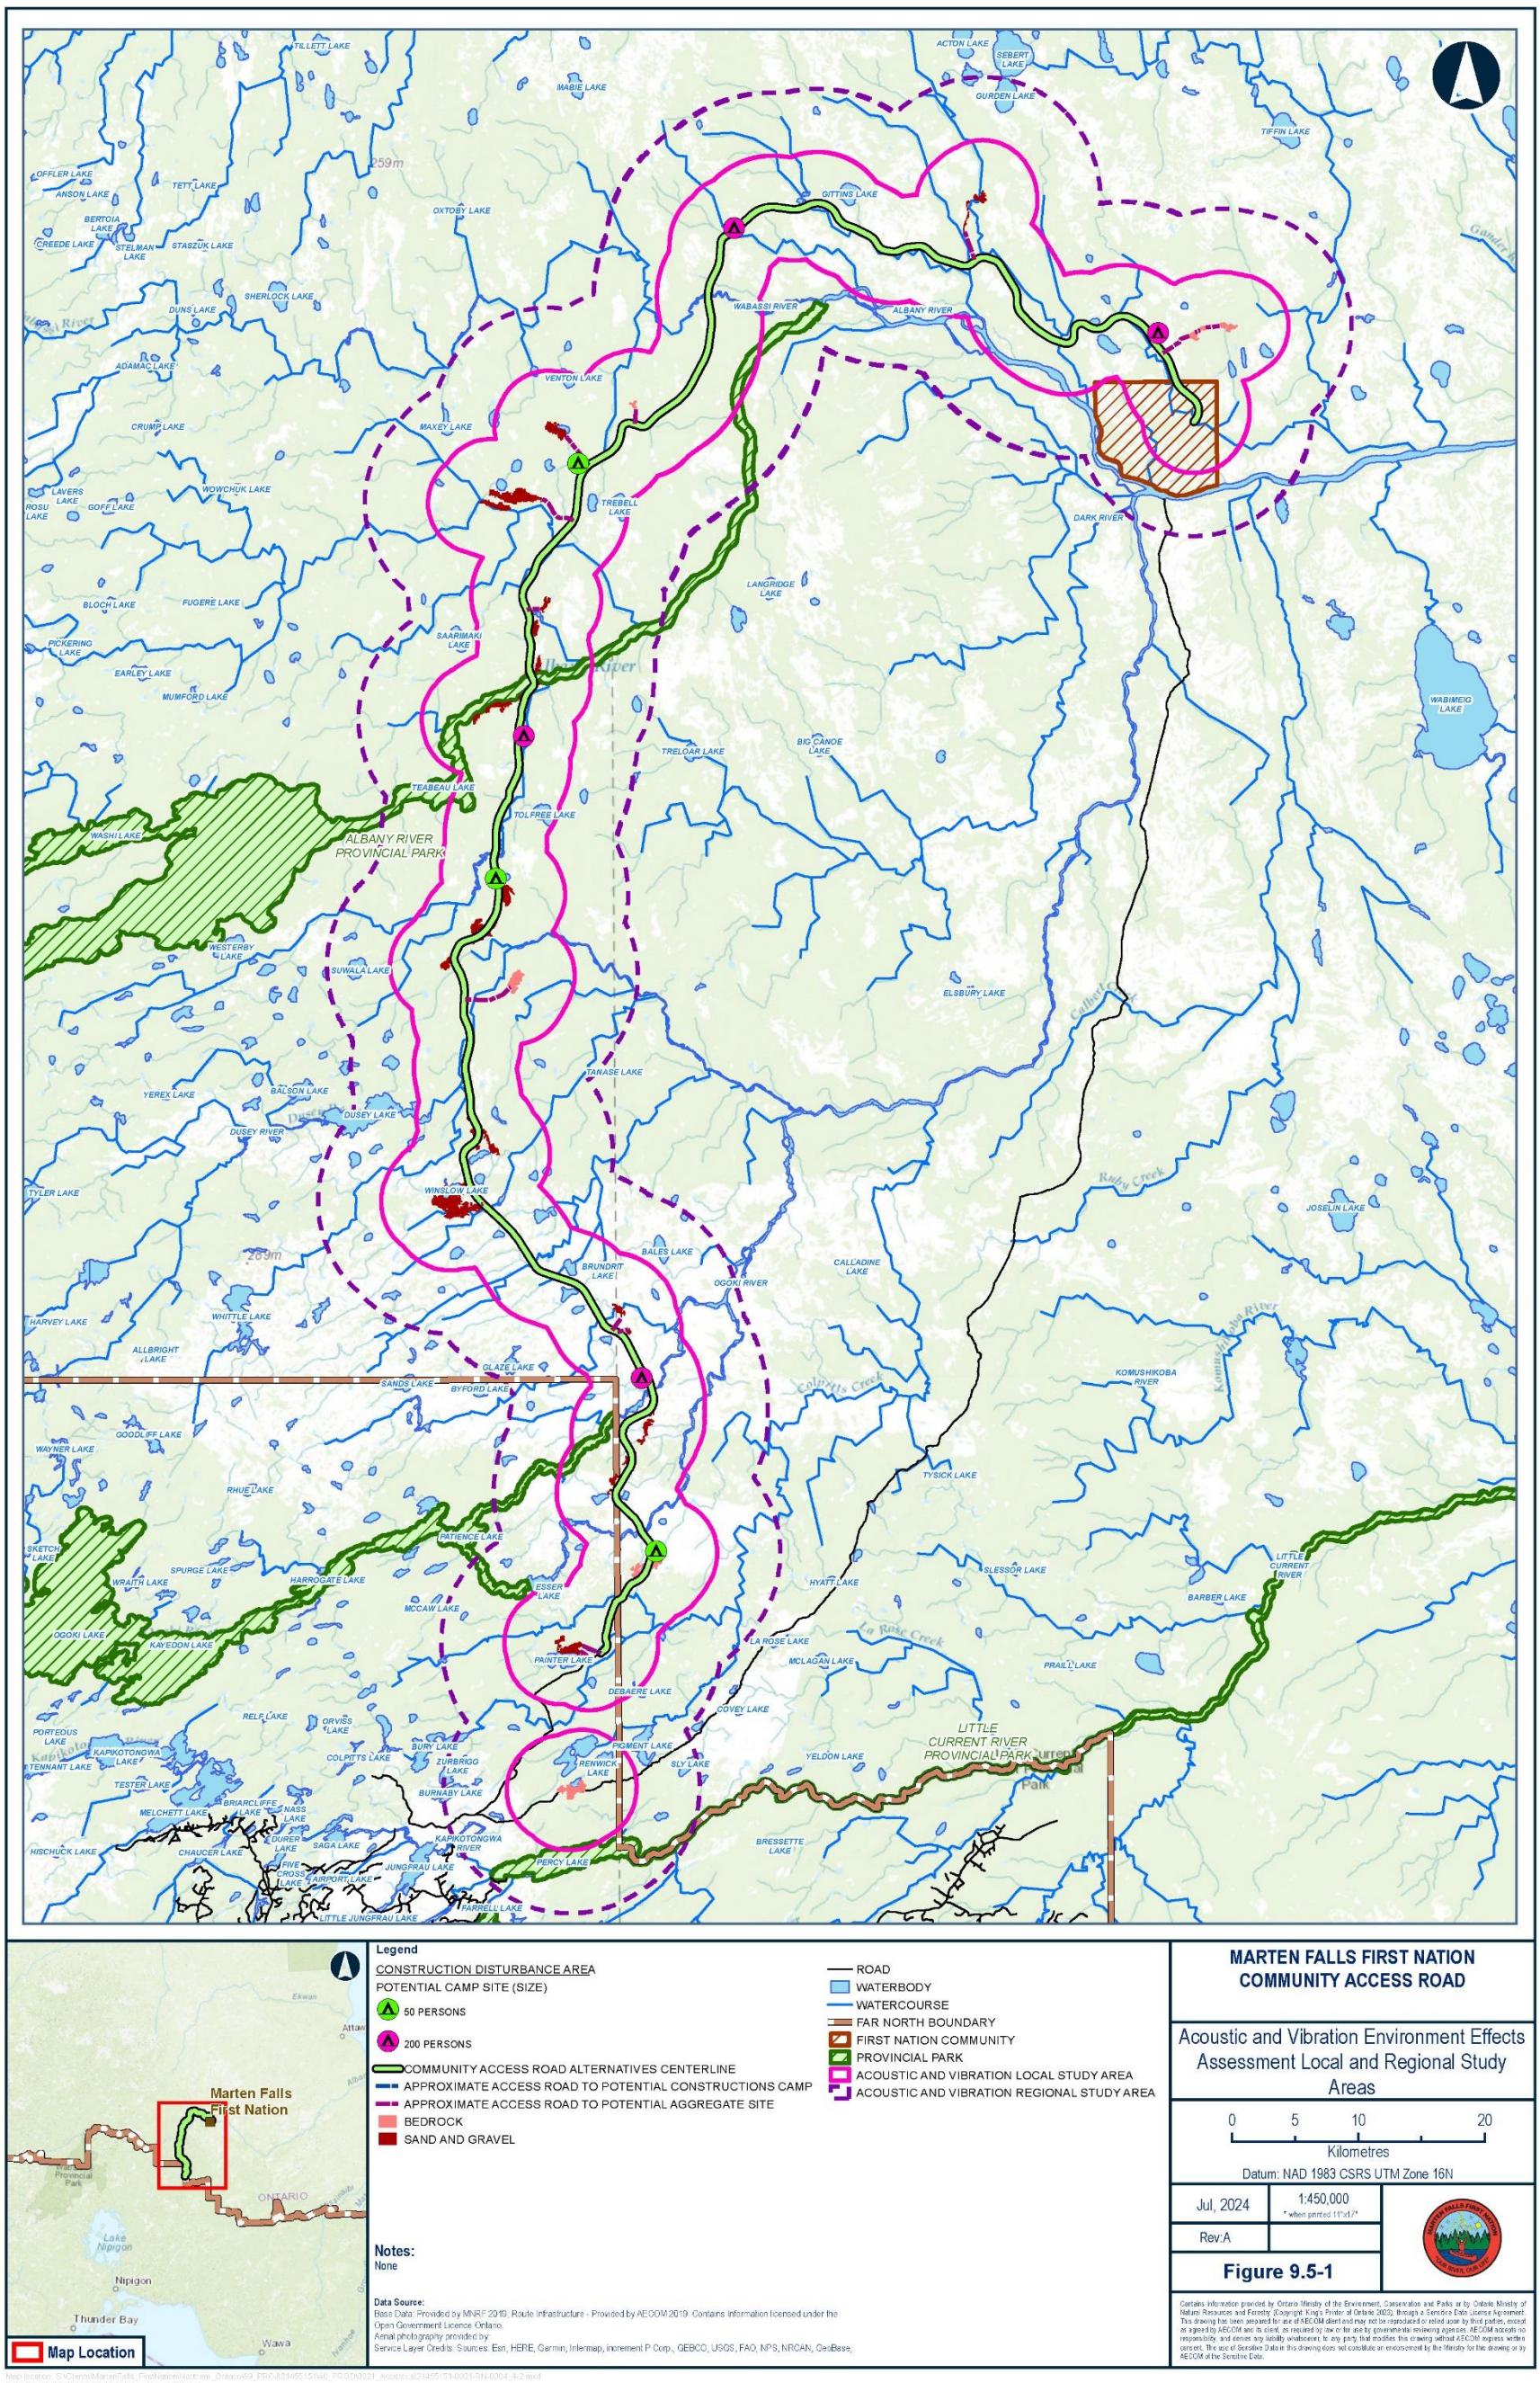
The anticipated changes to moose habitat availability and distribution from the Project are expected to remain within the resilience and adaptability limits of the regional population. However, it was precautionarily assumed that the Project could result in a significant change to moose population survival and reproduction due to potentially unsustainable harvest levels from increases in public access during operations. As such, the combined residual effects from the Project on moose and moose habitat are determined to have a significant influence on self-sustaining and ecologically effective moose populations.

9.4.7.6 Physiography, Terrain, and Soils

A determination of significance of residual effects on the physiography, terrain, and soils valued component cannot be completed as this valued component does not have an assessment endpoint. Assessment endpoints are qualitative expressions that represent the key properties of the environment that should be protected. Physiography, terrain, and soils are critical to the effects assessment and determination of significance for other biophysical valued component; however, the importance or significance of changes in physiography, terrain, and soils can only be evaluated in context of valued components with assessment endpoints, as these valued components are the ultimate receptors of value to humans and the environment.

9.5 People

"Anishinaabe bimaadiziwin (an Anishinaabe way of living) and mino-bimaadiziwin (living a good life) are ways-of-being given to Anishinaabe people as part of their original instructions, which are reflected in the Creation story. It tells us how we were created from the earth and lowered to the earth; how the Creator had such incredible love for us, and therefore gave us gifts from Creation (such as wind / air, fire, and water) to house within our bodies. This incredible love is re-enacted in our children, as they are not to take life for granted; they are to appreciate life and be affirmed through cultural traditions and practices that they are the life of the people. When the first being was created, s/he looked back through each of the four levels of Creation to always remember where s/he came from – the incredible love of the Creator. The one first lowered to earth had such incredible respect for the earth when s/he touched down upon all her beauty that s/he did not even want to bend one blade of grass. S/he teaches the Anishinaabe people to have the utmost respect for the earth, as they depend on her for their survival. Respect is, therefore, spirit given. It is important for Anishinaabe children to know that they come from the Creator. The Creation story illustrates this for them and provides them with all of the values they need in order to fulfill the Creator's instructions of living in a good way (mino-bimaadiziwin) and celebrating life. When life is disrespected, there is a belief that that disrespect will come back to you and something will happen to you – termed as oohjine in the Anishinaabe language. There is good and bad in everything – water gives life, yet you can drown in it. Everything must be respected for this reason." (Bell, 2016).



9.5.1 Spatial Boundaries of People Disciplines

As part of the effects assessment exercise, some disciplines revised their study areas based on the development of the Preferred Route. The updated study areas for Aboriginal and / or Treaty Rights and Interest, acoustic environment, atmospheric environment, archaeological and cultural heritage, community well-being, land and resource use and visual environment are defined in **Table 9.5-1** and shown on **Figure 9.5-1**.

Table 9.5-1: People Study Areas

Discipline(s)	Construction Disturbance Area	Local Study Area	Regional Study Area
• Aboriginal and Treaty Rights and Interests	• No change from **Section 8**	• No change from **Section 8**	• No change from **Section 8**
• Acoustic and Vibration	• No change from **Section 8**	• No change from **Section 8**	• No change from **Section 8**
• Atmospheric (Air Quality)	• Construction Disturbance Area plus a 5-kilometre buffer that extends from the perimeter of the Construction Disturbance Area	• A Local Study Area has been selected to align with the Ontario Ministry of the Environment, Conservation and Parks recommendations for local dispersion modelling, which is that effects be assessed up to 5 kilometres from a source (Ministry of the Environment, Conservation and Parks, 2018). • Area Size: 239,095 hectares	• Not applicable as effects are not expected beyond the Local Study Area.
• Atmospheric (Green House Gas)	• No change from **Section 8**	• No change from **Section 8**	• No change from **Section 8**
• Archaeology and Cultural Heritage (Archaeology)	• No change from **Section 8**	• No change from **Section 8**	• No Change from **Section 8**
• Archaeology and Cultural Heritage (Cultural Heritage)	• No change from **Section 8**	• No change from **Section 8**	• No change from **Section 8**
• Community Well-Being	• No change from **Section 8**	• No change from **Section 8**	• No change from **Section 8**
• Land and Resource Use	• No change from **Section 8**	• No change from **Section 8**	• No change from **Section 8**
• Visual Environment	• No change from **Section 8**	• No change from **Section 8**	• Refer to technical support document (**Appendix V**)

Figure 9.5-1 Acoustic and Vibration Environment Effects Assessment Local and Regional Study Areas

9.5.2 Aboriginal and / or Treaty Rights and Interests

As described in **Section 8.3.4**, an assessment was done for the each of the 23 Indigenous communities listed in **Section 11.2.** Communities received detailed reports describing existing conditions and potential interactions with Aboriginal and / or Treaty Rights and Interests, and were given the opportunity to review and provide feedback on draft versions. To support regulatory review, these reports will be submitted to the Regulator as part of the evidence base for determining assessment outcomes. Due to confidentiality and the sensitive nature of the information, **the detailed reports will not be shared publicly.** As a result, the following sections provide a high-level summary of the methodology used in these assessments.

Each confidential, community-specific Aboriginal and / or Treaty Rights and Interests Impact Assessment Report provides results for the Preferred Route, considering the Project's temporal boundaries. These reports outline potential positive and negative impacts, proposed mitigation and enhancement measures, and an assessment of residual impacts. Where relevant, Gender-Based Analysis Plus was applied to each Valued Component to address differential effects across community segments.

9.5.2.1 Project-Environment Interactions

The assessment examined potential interactions between the Project and each Indigenous community's Aboriginal and / or Treaty Rights and Interests. This was done by comparing Areas of Interest with defined Study Areas, incorporating input from Indigenous communities through consultation and Indigenous Knowledge programs, reviewing available information on existing conditions, and evaluating possible impacts from Project construction, operation, and maintenance. It is the Proponent's understanding that Areas of Interest are where each Indigenous community may exercise / hold Aboriginal and / or Treaty Rights and Interests and practice culture.

Each confidential, community-specific report considered two valued components: **Indigenous Current Use of Lands and Resources for Traditional Purposes** and **Cultural Continuity and Well-being**, including analysis of spatial overlaps and potential impacts on rights. This process was carried out for every Indigenous community and shared directly to them in their community-specific and confidential Aboriginal and / or Treaty Rights and Interests: Impact Assessment Report. These are not being shared publicly to protect sensitive information.

9.5.2.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following Aboriginal and / or Treaty Rights and Interests definitions apply to the effects assessment.

Ecological and Social Context

The assessment of Aboriginal and / or Treaty Rights and Interests incorporated both social and ecological context when characterizing residual impacts. This involved evaluating existing and potential pressures on social, economic, health, and cultural conditions that influence the sensitivity or resilience of valued components. The analysis considered factors such as reversibility of impacts, timing during culturally significant periods, and cumulative stresses that may affect an Indigenous community's ability to exercise rights. Disproportionate effects on specific groups within communities (for example, Elders, women, youth, two-spirit individuals) were addressed through a Gender-Based Analysis Plus approach, recognizing that impacts may be experienced differently across segments of the population and may extend to future generations. Indigenous Knowledge was incorporated where available to inform ecological context, including species sensitivity and resilience. These considerations confirmed that the assessment accounted for both the nature of predicted impacts and the broader social and cultural consequences for Aboriginal and / or Treaty Rights and Interests.

Magnitude

When evaluating the magnitude of effects / impacts, the assessment considers both the proportion of the valued component affected within identified spatial boundaries and the relative effect / impact.

Given the differences in social and ecological context among the valued components, definitions specific to valued components were required. Definitions used for the Aboriginal and / or Treaty Rights and Interests assessment are provided in **Table 9.5-2.**

Table 9.5-2: Magnitude Definitions for Aboriginal and / or Treaty Rights and Interests

Magnitude Level	Definition	Rationale
• **Negligible**	• No or very little discernable change from existing conditions and effect will not interfere with the ability to exercise or practice Aboriginal Treaty and / or Rights and Interests.	• Negligible effects are small and may not be noticeable. These effects do not represent a change in the day-to-day exercise or practice of Aboriginal Treaty and / or Rights and Interests.
• **Low**	• A small, discernable change from existing conditions but effect not expected to materially impede the ability to exercise or practice Aboriginal Treaty and / or Rights and Interests (for example, impacts not expected within areas of preferred or exclusive use, no or little indication there would be an impact on areas of cultural importance, the Indigenous community or group has expressed only minor concerns and has indicated that the Project risks are acceptable or have been sufficiently mitigated or accommodated).	• Low effects may be noticeable to some Indigenous community members. These effects do not represent a change in day-to-day exercise or practice of Aboriginal Treaty and / or Rights and Interests.
• **Moderate**	• A discernable change from existing conditions that is expected to impede the ability to exercise or practice of Aboriginal Treaty and / or Rights and Interests (for example, impacts may occur within areas of preferred use, may be an impact on areas or traditions of cultural importance that may impede ability to access and practice, potential physical or sensory disturbance, the Indigenous community or group has expressed concerns that some impacts remain after mitigation and / or accommodation and the Project may not be compatible with certain aspects of their land use plans or the application of traditional governance and stewardship).	• Moderate effects are noticeable to some Indigenous community members. These effects may or may not represent a change in the exercise or practice of Aboriginal Treaty and / or Rights and Interests.
• **High**	• A discernable change from existing conditions that is expected to severely or totally impede the ability to exercise or practice of Aboriginal Treaty and / or Rights and Interests (for example, impacts expected within areas of preferred use or that are considered high value, likely impact on areas and / or traditions of cultural importance, access to areas used to exercise rights will be disrupted or impeded, the Project may affect traditional laws, knowledge, and / or spiritual and cultural traditions).	• High effects are noticeable to Indigenous community members. These effects represent a notable change in the exercise or practice of Aboriginal Treaty and / or Rights and Interests.

Duration, Frequency, Reversibility and Likelihood

Definitions used for duration, frequency, reversibility, and likelihood for the Aboriginal and / or Treaty Rights and Interests assessment are provided in **Table 9.5-3**. These definitions were developed to provide additional contextual nuance relevant to Indigenous communities and groups and Aboriginal and / or Treaty Rights and Interests.

Table 9.5-3: Duration, Frequency, Reversibility and Likelihood Definitions used for Aboriginal and / or Treaty Rights and Interests Assessment

Impact Characteristic	Definition
• **Duration**	• **Short-term:** impact ends before the end of construction (in other words, within the duration of construction). • **Medium-term:** the impact occurs during construction and ends soon after operation begins and / or maintenance ends, soon after the activity causing the impact ends (in other words, may last up to one generation). • **Long-term:** the impact occurs during construction and persists into operation and / or the impact is considered permanent or the likelihood of reversibility is low or uncertain (in other words, the impact is likely to persist over multiple generations).
• **Frequency**	• **Infrequent:** The impact is expected to occur rarely (in other words, confined to one discrete period). • **Frequent:** The impact is expected to occur intermittently (in other words, daily, weekly, monthly). • **Continuous:** The impact is expected to occur continuously (in other words, the impact would occur constantly).
• **Reversibility**	• **Reversible:** the impact is not permanent (in other words, may be reversed in the short term or within one generation). • **Irreversible:** the impact is permanent (in other words, cannot be reversed in whole or in part).
• **Likelihood**	• **Unlikely:** the impact is not likely to occur. • **Possible:** the impact may occur. • **Probable:** the impact is likely to occur. • **Certain:** the impact will occur.

9.5.2.3 Residual Effects

The residual impact assessment for the Preferred Route considered both temporal phases of the Project: construction and operations. Construction includes site preparation, temporary works, and decommissioning activities, and is expected to take approximately 3 to 10 years. Operations begins after construction and is considered permanent, based on the anticipated timeline for major refurbishments. Results of the

residual impact assessment were shared confidentially with Indigenous communities in their community-specific reports.

The assessment identified potential impacts on Aboriginal and / or Treaty Rights and Interests, recommended mitigation measures, and evaluated residual impacts after mitigation, including severity and prediction confidence. Severity was determined using characteristics such as context, direction, magnitude, geographic extent, duration, frequency, reversibility, and likelihood. Predicted residual impacts were then incorporated into the cumulative impact assessment. Gender-Based Analysis Plus was applied where information on demographic roles and experiences within Indigenous communities was available; however, such data was limited for many communities.

9.5.2.3.1 Indigenous Current Use of Lands and Resources for Traditional Purposes

Potential Impacts

In each community-specific report, a description of the overlap (or lack of overlap) was described and included:

- A map illustrating the Area of Interest in relation to the Study Areas;
- Percentage of Area of Interest overlap with the:
  - Construction Disturbance Area;
  - Aboriginal and / or Treaty Rights and Interests Local Study Area;
  - Aboriginal and / or Treaty Rights and Interests Regional Study Area; and
  - Caribou Regional Study Area.

Based on the results of the above, it was determined if there was a potential for interaction between the Project and each Indigenous community's ability to exercise their rights related to the use of lands and resources for traditional purposes in the Construction Disturbance Area, the Aboriginal and / or Treaty Rights and Interests Local and Regional Study Areas, and the Caribou Regional Study Area.

Predicted Residual Impacts

In each community-specific Aboriginal and / or Treaty Rights and Interests Impact Assessment Report, a description of the potential impact pathways for Cultural Continuity and Well-being were carried forward (for example, changes in the experience of being on the land).

For each indicator pathway carried forward the following assessment sections were completed:

- A description of the potential Project effect on rights. For example, the Project has the potential to affect the experience of being on the land (in terms of freedom from disturbance) due to changes in the air, noise, and visual environments.
- An overview of the potential Project effects after mitigation. For example, noise levels will increase during construction as a result of road and bridge construction and pit / quarry construction and use.
- A description of the potential impacts on rights as a result of the Project. For example, changes to the noise environment, especially during construction, may lead to noticeable changes in noise levels, affecting experiences of peace and solitude.
- A summary of mitigation measures proposed. For example, provide Indigenous communities with advance notices and regular updates regarding location and timing of construction activities, including bridge construction and blasting operations.
- An assessment of predicted residual impacts on rights including context, Project phase(s), direction, magnitude, geographic extent, duration, frequency, reversibility, and likelihood.
- An assessment of the severity of the residual impacts and associated prediction confidence.

A summary of the predicted residual impacts and the determination of severity for the Aboriginal and / or Treaty Rights and Interests valued components was provided in Table 7-3 of each community-specific Aboriginal and / or Treaty Rights and Interests Impact Assessment Report.

9.5.2.3.2 Cultural Continuity and Well-being

Potential Impacts

If an interaction was noted in **Section 9.5.2.3.1**, then an Indigenous community may exercise their rights within these areas. If these rights are negatively impacted, this may, in turn, lead to changes in that Indigenous community's cultural continuity and well-being. In each community-specific report, a description of this interaction was provided.

Predicted Residual Impacts

In each community-specific Aboriginal and / or Treaty Rights and Interests Impact Assessment Report, a description of the potential impact pathways for Cultural Continuity and Well-being were carried forward (for example, changes in the experience of being on the land).

For each indicator pathway carried forward the following assessment sections were completed:

- A description of the potential Project effect on rights. For example, the Project has the potential to affect the experience of being on the land (in terms of freedom from disturbance) due to changes in the air, noise, and visual environments.
- An overview of the potential Project effects after mitigation. For example, noise levels will increase during construction as a result of road and bridge construction and pit / quarry construction and use.
- A description of the potential impacts on rights as a result of the Project. For example, changes to the noise environment, especially during construction, may lead to noticeable changes in noise levels, affecting experiences of peace and solitude.
- A summary of mitigation measures proposed. For example, provide Indigenous communities with advance notices and regular updates regarding location and timing of construction activities, including bridge construction and blasting operations.
- An assessment of predicted residual impacts on rights including context, Project phase(s), direction, magnitude, geographic extent, duration, frequency, reversibility, and likelihood.
- An assessment of the severity of the residual impacts and associated prediction confidence.

A summary of the predicted residual impacts and the determination of severity for the Aboriginal and / or Treaty Rights and Interests valued components was provided in Table 7-3 of each community-specific Aboriginal and / or Treaty Rights and Interests Impact Assessment Report.

It is important to note that the Project will result in some positive effects for the Aboriginal and / or Treaty Rights and Interests valued components.

Changes in Access to Sites and Areas Used for Traditional Purposes: The Project will enhance connectivity to remote regions and expand access to sites and areas that support traditional land and resource use, including:

- Access to harvesting areas and opening locations that were previously difficult to reach and supporting hunting, trapping, and fishing for local Indigenous communities.
- Access to sites used for traditional activities, including hunting, trapping, fishing, and gathering.
- Access to previously isolated grounds for berry picking and medicinal plant gathering.
- Access to local harvesting of traditional foods and support for community food sharing.
- Access to traplines, improving mobility for trappers.
- Access to areas used for ceremonial and spiritual practices.

The Project will improve access to currently remote areas and may benefit Indigenous communities already connected to the provincial road network by making it easier to exercise traditional land use rights. Shorter and safer travel to hunting, trapping, and fishing grounds can extend seasons, lower costs, and strengthen traditional harvesting. New routes to berry patches and medicinal plant sites support gathering across seasons, while better access to traplines supports set up and maintenance. Improved connectivity to ceremonial and teaching places reinforces cultural practices and intergenerational knowledge transfer. Enhanced access to the land can also bolster food security and sustain community food sharing.

Changes to Connection to the Land and Ability to Practice and Transmit Cultural Traditions: Positive impacts that could result from the Project include improved access to, and use of, traditional lands, teaching sites, and cultural areas, supporting the following outcomes:

- Elders and knowledge holders can more readily teach how to hunt, fish, trap, and process foods, strengthening intergenerational knowledge transfer.
- Time on the land strengthens life skills and cultural values alongside technical harvesting skills.
- Increased time on the land supports everyday use of Indigenous languages and helps counter language loss tied to disconnection from traditional practices.

- Traditional activities engage men, women, youth, and children in preparing, cooking, and distributing country foods, reinforcing communal roles and responsibilities.
- Sharing harvested foods strengthens social bonds and intergenerational ties, promotes distribution, and enhances food security.
- Easier access enables more frequent participation in harvesting and cultural activities, deepening connections to language, culture, and ways of life.
- Improved mobility supports communities seeking to renew and revitalize cultural traditions and practices on the land.

By improving access to traditional lands and teaching sites, the Project is also expected to deliver positive outcomes. Elders and knowledge holders can more readily teach hunting, fishing, trapping, and food processing, strengthening intergenerational knowledge transfer. More time on the land reinforces life skills and cultural values alongside technical harvesting and supports everyday use of Indigenous languages. The whole community becomes engaged in preparing and sharing country foods, strengthening social bonds and enhancing food security. Easier access encourages participation in cultural activities and deepens connections to language and culture.

Improved access to the land enables Elders and knowledge holders to teach hunting, fishing, trapping, and food processing, strengthening intergenerational knowledge transfer. More time on the land builds life skills and cultural values alongside technical harvesting and supports everyday use of Indigenous languages. Traditional activities engage the whole community in preparing and sharing country foods, reinforcing roles, social bonds, and food security. Easier access increases participation and deepens connections to language and culture, while overall mobility supports the renewal and revitalization of land-based traditions.

9.5.3 Acoustic Environment

9.5.3.1 Project-Environment Interactions

As a component of the effects assessment, the Project activities for Acoustics were reviewed to find potential environmental interactions. These interactions were then assessed for potential effect (**Table 9.5-4**).

Table 9.5-4: Project-Environment Interactions - Acoustic Environment

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction**	• Temporary Construction Staging Areas	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between temporary construction staging areas construction and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Temporary Access Roads and Trails	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between temporary access road and trail construction and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Temporary Construction Camps	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between temporary construction camp construction and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Right-of-way Clearing and Grubbing	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between right-of-way clearing and grubbing and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Pits and Quarries	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity • Air overpressure	• Potential interactions between pit and quarry use and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Temporary Concrete Batch Plants	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between the use of temporary concrete batch plants and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Drilling / Blasting / Aggregate Production	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity • Air overpressure	• Potential interactions between aggregate production, including drilling and blasting, and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction**	• Road Construction (stripping, subgrade excavation, embankment fill placement, grading, ditching)	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between road construction and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Bridge and Culvert Installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls)	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between bridge and culvert construction and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Construction Site Restoration	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between construction site restoration and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*.	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between pit and quarry decommissioning and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Construction**	• Decommissioning of Temporary Camps, Roads / Trails, and Staging Areas	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between decommissioning of temporary camps, roads, trails and staging areas and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Operations**	• Road Usage	• Noise and Vibration	• Day-night sound level • Daytime sound level (Footnote a) • Nighttime sound level • Maximum nighttime sound level • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between road usage and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.
• **Operations**	• Maintenance (Footnote b)	• Noise and Vibration	• Continuous 1-hour equivalent sound level • Day-night sound level • Daytime sound level (Footnote a) • Percent highly annoyed • Peak particle ground vibration velocity • Root-mean square ground vibration velocity	• Potential interactions between maintenance and noise and vibration are anticipated. • Potential effects associated with this activity are further described in this Application.

Footnotes: (a) The definition of daytime sound level depends on the guidance document being considered. When assessing construction and operations activities, daytime sound level is defined as 7 a.m. to 10 p.m. When assessing road usage, daytime sound level is defined as 7 a.m. to 11 p.m.

(b) Includes general maintenance (for example grading, erosion control, quarrying, pits), seasonal maintenance (for example snow clearing, bridge and culvert maintenance), and special maintenance (for example slope failures, road settlement / break up).

9.5.3.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following acoustic definitions apply to the effects assessment.

Ecological and Social Context

Ecological context for the acoustic and vibration environment valued component considers noise and vibration sensitivity, timing of an effect in relation to the duration and frequency of use of identified points of reception, applicable legislation and best management practices. The current and future sensitivity of the acoustic and vibration environment to change caused by the Community Access Road are considered and includes Indigenous Knowledge where it was available.

Magnitude

For magnitude, environmental discipline-specific definitions are required and are provided in **Table 9.5-5**. Magnitude of effects are project-related and exclude variations due to climate change.

Table 9.5-5: Acoustic and Vibration Valued Component

Valued Component	Definition	Rationale
• **Noise**	• Project noise levels do not exceed federal and provincial limits	• Established noise limits based on federal and provincial guidance
• **Vibration**	• Project vibration levels do not exceed reference municipal and industry limits	• Established vibration limits based on municipal (within Ontario) guidance and standard industry thresholds
• **Noise**	• Project noise levels exceed federal and provincial limits	• Established noise limits based on federal and provincial guidance
• **Vibration**	• Project vibration levels exceed reference municipal and industry limits	• Established vibration limits based on municipal (within Ontario) guidance and standard industry thresholds

9.5.3.3 Residual Effects – Construction Phase

9.5.3.3.1 Changes to Noise Level

9.5.3.3.1.1 Potential Effects

Noise levels can be expected to increase, on occasion, due to construction activities at the potential points of reception, but construction noise will be temporary in nature and

localized within the Local Study Area. The range in increased noise levels associated with construction activities will depend primarily on the number and type of noise sources and their proximity to the points of reception (in other words, the Project noise levels in the environment decrease as the distance between the points of reception and construction activities increases).

Table 9.5-6, **Table 9.5-7**, and **Table 9.5-8** and **Figure 9.5-2**, **Figure 9.5-3**, and **Figure 9.5-4** present the predicted noise levels from road construction, bridge construction, and pit and quarry construction and use, respectively, associated with the Project. The tables also indicate the applicable noise limit for each parameter and indicates where noise levels exceed these limits in bold / underline.

The results in **Table 9.5-6** and **Figure 9.5-2** indicate that during road construction, noise levels may exceed Health Canada's daytime criteria for speech comprehension and day-night criteria for noise complaints (in other words, 55 A-weighted decibels) at points of reception within 1,000 metres of the effects assessment Construction Disturbance Area along the Community Access Road. It also indicates that exceedances of Health Canada's change in percent highly annoyed criteria may occur at points of reception within the Local Study Area.

The results in **Table 9.5-7** and **Figure 9.5-3** indicate that during bridge construction, noise levels may exceed Health Canada's daytime criteria for speech comprehension and day-night criteria for noise complaints (in other words, 55 A-weighted decibels) and change in percent highly annoyed criteria at points of reception within the Local Study Area.

The results in **Table 9.5-8** and **Figure 9.5-4** indicate that during construction and use of pits and quarries, noise levels may exceed Health Canada's daytime criteria for speech comprehension and day-night criteria for noise complaints (in other words, 55 A-weighted decibels) and change in percent highly annoyed criteria at points of reception within 200 metres of the effects assessment Construction Disturbance Area surrounding the pits and quarries.

Table 9.5-6: Summary of Predicted Noise Levels at Points of Reception During Road Construction

Distances from the Construction Disturbance Area	Number of Potential Points of Reception – No Habitation Expected (Footnote a)	Number of Potential Points of Reception – Habitation May Occur (Footnote b)	Project Daytime (Footnote c) Noise Level (dBA)	Existing + Project Daytime (Footnote c) Noise Level (dBA)	Existing + Project Day-Night Noise Level (dBA) (Footnote d), (Footnote e)	Change in Percent Highly Annoyed (percent) (Footnote d)

9.5.3.3.1.2 Mitigation and Enhancement Measures

The following is a general summary of the items to be considered relating to construction noise according to the Ontario Ministry of Transportation Noise Guide (Ontario Ministry of Transportation, 2022):

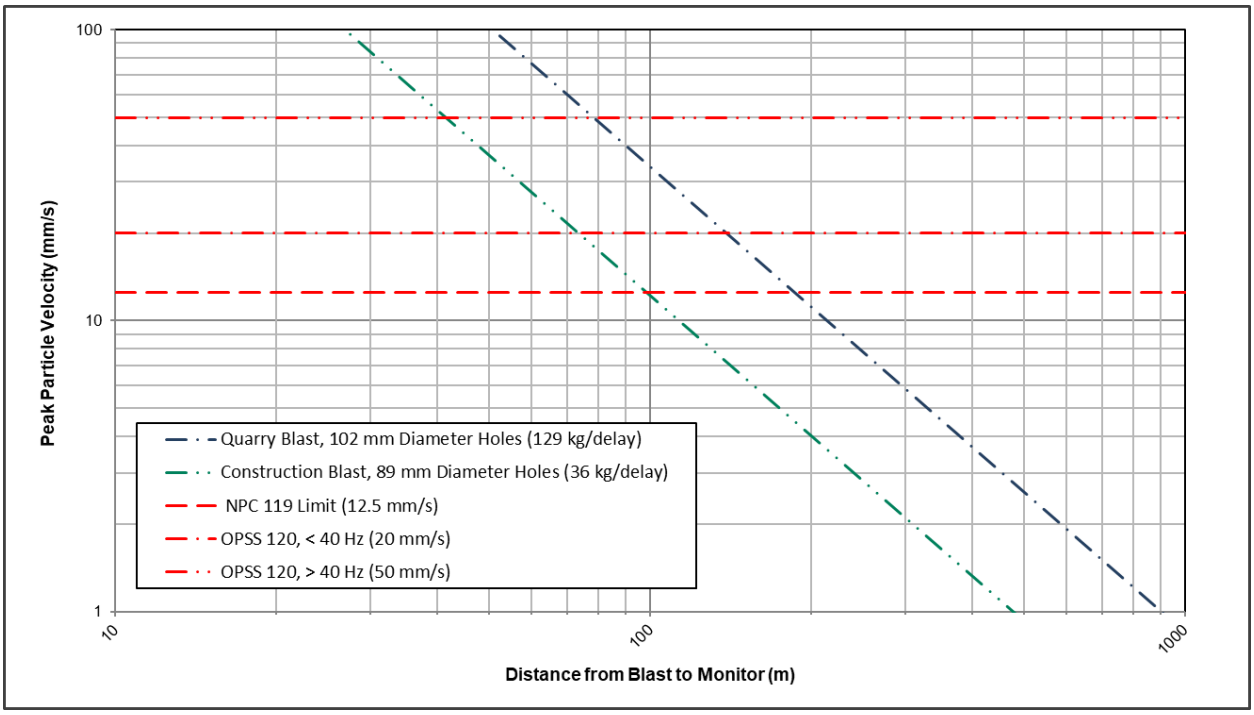
- Conduct construction activities, including quarry use, during the daytime period (in other words, 7 a.m. to 7 p.m.). Nighttime work is not anticipated. In the event construction will occur beyond the daytime period, applicable mitigation measures will be reviewed and implemented as required;
- Check that equipment and machinery used on site is maintained in good working conditions through regular maintenance and inspection;
- Design access roads to minimize reversing, which is expected to minimize use of backup beepers, where possible;
- Locate and operate construction equipment as far as possible from points of reception;
- Engage with Indigenous communities and relevant stakeholders to coordinate the planned construction schedule before the start of construction and prior to specific noisy activities to minimize overlap with the timing of traditional land use activities (for example, fall and spring hunting seasons);
- Where reasonable and practicable, turn off vehicles and equipment when idle, unless weather and / or safety conditions dictate the need for them to remain turned on and in a safe operating condition;
- Maintain the surface of the road such that rough surface conditions are avoided;
- Investigate noise concerns as they arise through a complaint resolution mechanism developed by the owner / operator whereby persons can contact the Project team if there are perceived noise issues; and
- Operate vehicles and equipment to minimize impulsive noise, where possible.

9.5.3.3.1.3 Predicted Residual Effects

Noise emissions during construction may result in a potential effect because it is predicted that, after the implementation of impact management measures, exceedances of applicable criteria at potential points of reception may occur. This potential effect is therefore carried through for further assessment in the following sections, including an assessment of significance.

9.5.3.3.2 Changes to Vibration Levels

9.5.3.3.2.1 Potential Effects



Blasting

Existing vibration levels can be expected to increase, on occasion, due to the construction blasting and quarry blasting activities at nearby points of reception, but blast-induced vibration is expected to be temporary in nature, occur only during specific activities, and limited to the vicinity of the Project footprint within the Study Area. The range in increased vibration levels associated with construction blasting will depend primarily on the maximum explosive weight detonated at any given instance and the proximity to the points of reception (in other words, the Project vibration levels in the environment generally decrease as the distance between the point of reception and maximum charge weight detonated at a given instance [in other words, delay period]).

Potential effects on vibration levels during blasting for construction will vary based on type of blasting, but for the Project, vibration effects are expected to be greatest during quarry blasting and when construction blasting is required near an existing point of reception.

A semi-quantitative assessment of the potential blasting during construction was carried out using the Ministry of the Environment, Conservation and Parks (1985) vibration attenuation model and the blast parameters described in **Appendix P**. It is assumed the blasting activities will occur near where aggregate materials are required and / or where the local bedrock profile require construction blasts to achieve the proper elevations. As the exact locations for the required blasting are not currently known, the results are presented as distance between the blast and the nearest sensitive receptor. When the blast locations are identified, the effect on specific vibration sensitive receptors can be estimated. The predictive vibration and air overpressure models developed for the proposed blasting methods are shown graphically in **Figure 9.5-5** and **Figure 9.5-6**, respectively. These are summarized in **Table 9.5-9** and **Table 9.5-10**.

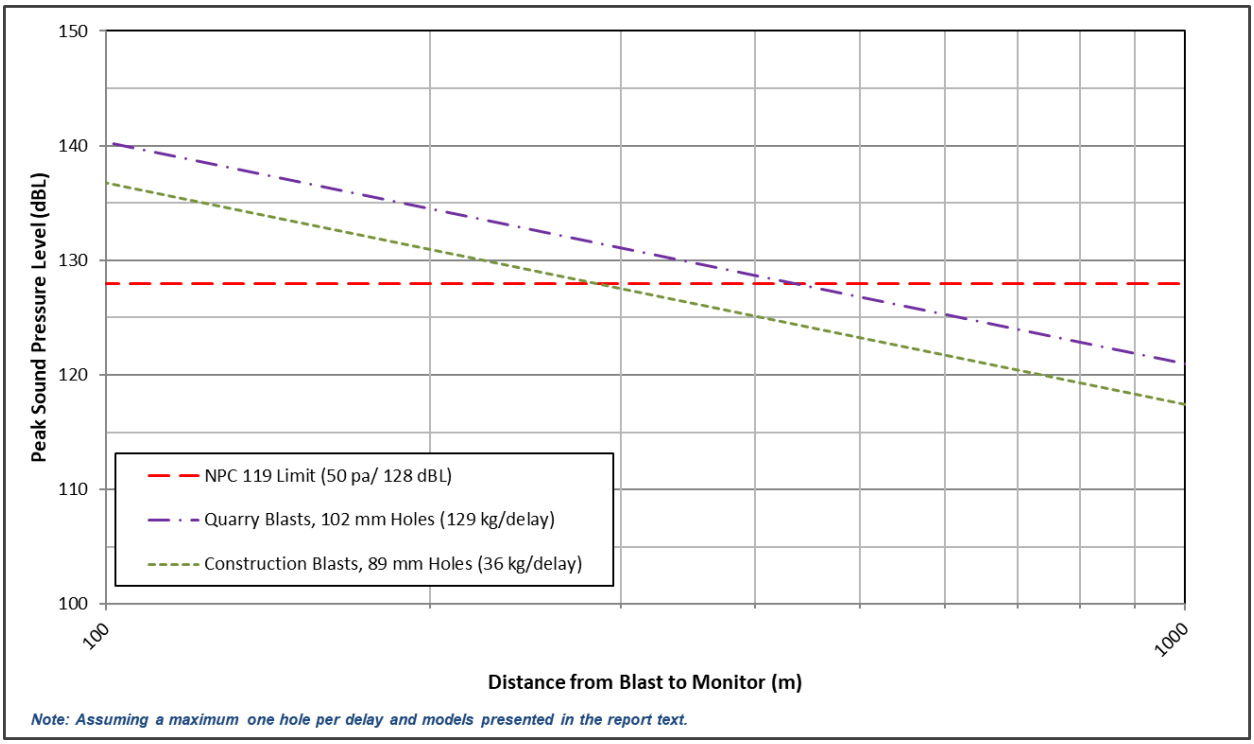
Figure 9.5-5: Estimated Vibration Level with Distance from Receptor

Footnotes: mm/s = millimetre per second; mm = millimetre; kg/delay = kilogram per delay; < = less than; > = greater than; Hz = hertz; m = metre.

The estimated vibration levels shown in **Figure 9.5-5** are summarized in **Table 9.5-9**.

Table 9.5-9: Estimated Ground Vibrations for the Assessed Blast Design at a Range of Distances

Distance (Footnote a) (metres)	Peak Particle Velocity (Footnote b) (millimetre per second)	
	Quarry Blasts	Construction Blasts
100	33.9	12.2
200	11.2	4.0
300	5.8	2.1
400	3.7	1.3
500	2.6	0.9
600	1.9	0.7
700	1.5	0.5
800	1.2	0.4
900	1.0	0.4
1,000	0.9	0.3



Footnotes: (a) Distance between the blast and the sensitive receptor.
(b) Assuming the attenuation models proposed previously.

Assuming a single hole per delay, the Ministry of the Environment, Conservation and Parks guideline limit of 12.5 millimetres per second may be complied with for all blasting beyond the following estimated standoff distances:

- Quarry blasts - 187 metres from the nearest receptor residence; and
- Construction blasts - 98 metres from the nearest receptor residence.

The estimated air overpressure levels are shown in **Figure 9.5-6** and summarized in **Table 9.5-10.**

Figure 9.5-6: Estimated Air Overpressure Level with Distance from Receptor

Footnotes: dBL = linear decibel; pa = pascal; mm = millimetre; kg/delay = kilogram per delay; m = metre.

Table 9.5-10: Estimated Ground Air Overpressure for the Proposed Blast Design at a Range of Distances

Distance (Footnote a) (metres)	Peak Sound Pressure Level (Footnote b) (linear decibel)	
	Quarry Blasts	Construction Blasts
75	143	139
100	140	137
200	135	131
300	131	128

Distance (Footnote a) (metres)	Peak Sound Pressure Level (Footnote b) (linear decibel)	
	Quarry Blasts	Construction Blasts
400	129	125
500	127	123
600	125	122
700	124	120
800	123	119
900	122	118
1000	121	117

Footnotes: (a) Distance between the blast and the sensitive receptor.
(b) Assuming the attenuation models proposed.

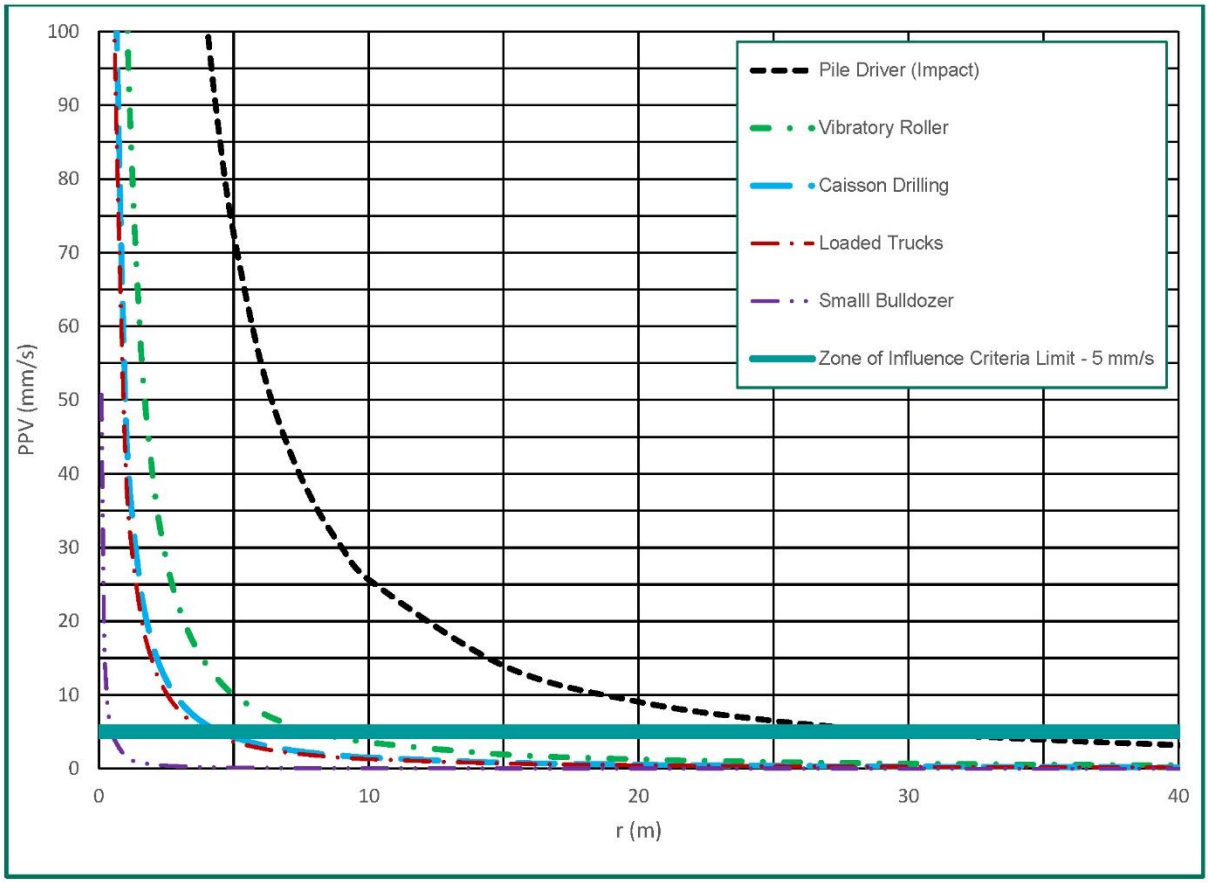
Assuming a single hole per delay, the Ministry of the Environment, Conservation and Parks guideline limit of 128 dBL may be complied with for all blasting measured in front of the face beyond the following estimated standoff distances from adjacent receptor locations:

- Quarry blasts – 430 metres; and
- Construction blasts – 300 metres.

Assuming a single hole per delay, the Health Canada guideline limit of 125 dBL for a single blast per day may be complied with for all blasting measured in front the face beyond the following estimated standoff distances from adjacent receptor locations:

- Quarry blasts – 600 metres; and
- Construction blasts – 400 metres.

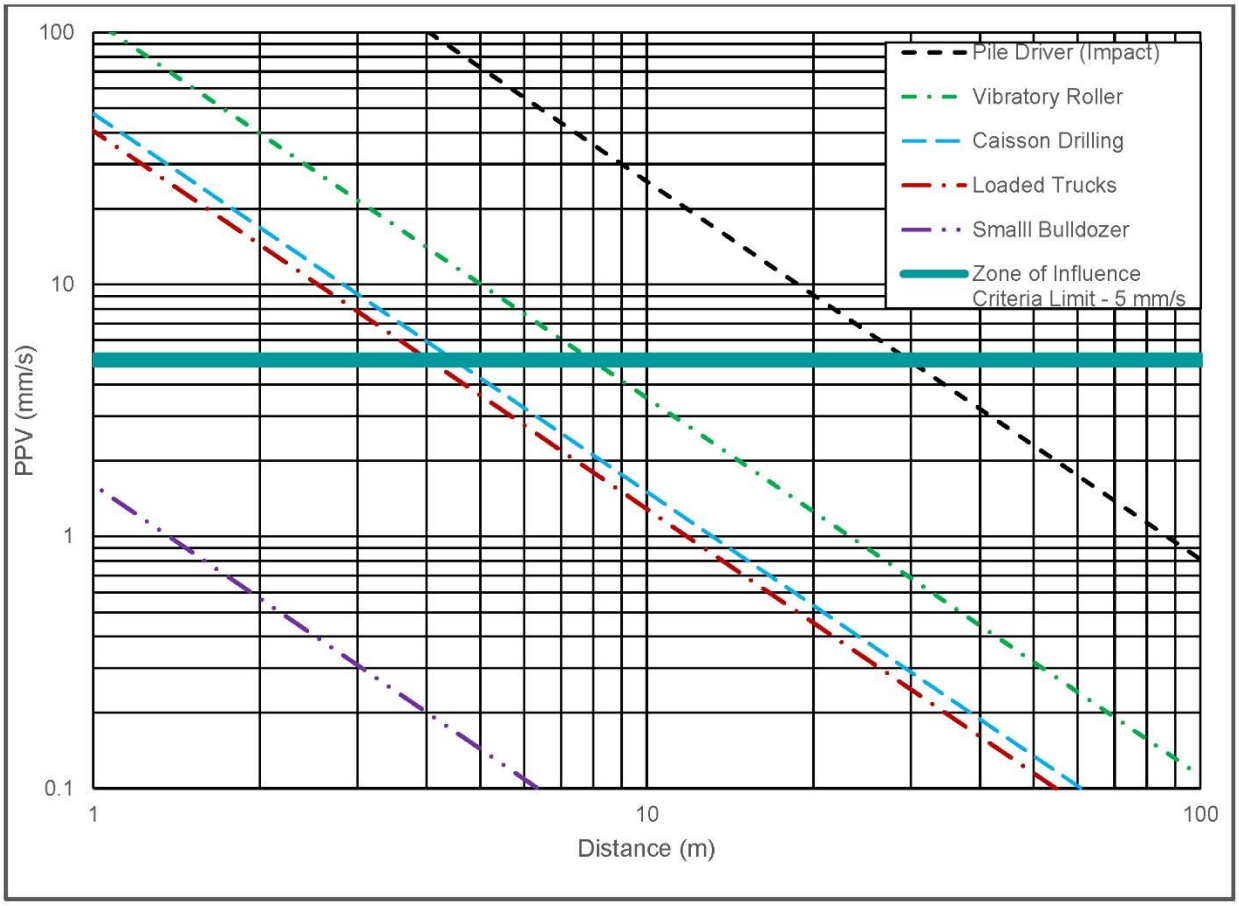
The estimated standoff distances do not consider the effect of vegetation (for example, trees) and local topography on the air vibration levels. If the construction blasts require the use of blast mats to control flyrock (in other words, ejected rock fragments and debris) the air overpressure will be reduced significantly.



General Construction Activities

Existing vibration levels can be expected to increase, on occasion, due to the general construction activities at nearby points of reception, but general construction vibration is expected to be temporary in nature, occur only during specific activities, and limited to the vicinity of the Project footprint within the Study Area. The range in increased vibration levels associated with general construction activities will depend primarily on the number and type of vibration sources and their proximity to the points of reception (in other words, the Project vibration levels in the environment generally decrease as the distance between the point of reception and construction activities increase). Potential effects on vibration levels during construction will vary based on type of

general construction activities, but for the Project, vibration effects are expected to be greatest during impact pile driving.



The assessment of the Project's general construction activities was carried out using the Transit Noise and Vibration Impact Assessment Manual vibration attenuation model. Select pieces of construction equipment were selected to present a range in potential vibration levels due to the Project general construction activities. It is assumed the general construction activities will occur anywhere within the Project right-of-way; therefore, the predicted zone of influence was considered to begin at the edge of the cleared section of the Project right-of-way (in other words, 30 metres from the Community Access Road centreline), unless otherwise stated below. The predictive vibration models developed for various proposed selected construction equipment and the zone of influence levels are shown graphically in linear and logarithmic scales in **Figure 9.5-7** and **Figure 9.5-8**, respectively.

Figure 9.5-7: Ground Vibration Attenuation Model for Various Proposed General Construction Activities – Linear Scale

Footnote: PPV = peak particle velocity; ZOI = zone of influence; mm/s = millimetre per second.

Figure 9.5-8: Ground Attenuation Model for Various Proposed General Construction Activities – Logarithmic Scale

Footnote: PPV = peak particle velocity; ZOI = zone of influence; mm/s = millimetre per second.

The City of Toronto Bylaw 514-2008 preliminary zone of influence criteria (in other words, 5 millimetres per second) for building damage may exist for some general construction equipment, which are expected to be the greatest source of vibrations, within the following estimated standoff distances:

- Impact pile driving – 30 metres from impact pile driving location. It is assumed any impact pile driving would occur within the edges of the road, therefore approximately 6 metres from the Community Access Road centreline (in other words, edge of road width);
  - Vibratory Roller – 8 metres from the cleared section of the Project right-of-way; and
  - Caisson Drilling – 5 metres from the cleared section of the Project right-of-way.

The Transit Noise and Vibration Impact Assessment Manual guideline limit of 0.1 millimetres per second for human annoyance may be complied with for some general construction equipment, which are expected to be the greatest source of vibration, beyond the following estimated standoff distances:

- Impact pile driving – 175 metres from impact pile driving location. It is assumed any impact pile driving would occur within the edges of the road, therefore approximately 6 metres from the Community Access Road centreline (such as, edge of road width);
  - Vibratory Roller – 50 metres from the cleared section of the Project right-of-way; and
  - Caisson Drilling – 25 metres from the cleared section of the Project right-of-way.

Based on the results of the vibration attenuation model, the predicted preliminary zone of influence (in other words, 5 millimetres per second) for building damage is within the right-of-way. Therefore, for the purposes of this assessment, a frequency-dependent analysis was not carried out for building damage.

Based on the results of the vibration attenuation model, the predicted general construction activities vibration levels at some of the identified representative points of reception exceed the human annoyance criteria considered for this vibration assessment. For the purposes of this assessment, a frequency-dependent analysis was not carried out for human annoyance. Therefore, potential vibration effects are expected during Project Construction at some of the points of reception and a detailed vibration assessment, including a frequency-dependent analysis, mitigation assessment as required and a monitoring program, is recommended to be carried out during detail design.

9.5.3.3.2.2 Mitigation and Enhancement Measures

The construction phase of any project is typically considered temporary or short term relative to the entire life cycle of a project. The following is a general summary of the items to be considered relating to construction vibration according to the various guidance documents and experience on similar projects.

As potential construction vibration effects are expected at some of the points of reception in the vicinity of the Project, the following are general recommendations to assist in minimizing vibration effects due to the Project's construction activities:

- Develop a Construction Vibration Workplan prior to the start of construction describing the construction schedule, list of construction equipment, list of point of reception locations (in other words, traditional land use, residential, heritage structures and utilities), applicable guidance documents including criteria and control measures;

- Consider the use of frequency-dependent vibration limits as more detailed information regarding the construction activities is known;
- Engage with Indigenous communities and relevant stakeholders to coordinate the planned construction schedule before the start of construction and prior to specific activities that may generate vibration to minimize overlap with the timing of traditional land use activities (for example, fall and spring hunting seasons);
- Investigate vibration concerns as they arise through a complaint resolution mechanism whereby persons can contact the Project team if there are perceived vibration issues;
- Conduct construction activities during the daytime period (such as, 7 a.m. to 7 p.m.). Nighttime work is not anticipated. In the event construction will occur beyond the daytime period, applicable mitigation measures will be reviewed and implemented as required;
- Locate and operate construction equipment as far as possible from points of reception;
- Maintain the surface of the road such that rough surface conditions are avoided;
- Avoid operating equipment that is expected to generate significant vibrations at the same time. Operating them separately may reduce overall vibration levels;
- Construction blasting will be carried out in compliance with the Ontario Provincial Standard Specification 120 and NPC-119. The Ontario Provincial Standard Specification 120 details items such as vibration limits, protective measures, pre-blast surveys and notification to nearby owners and tenants. All blasts which might impact local structures or disrupt humans will be monitored for ground and air vibrations;
- Blasting at temporary or existing quarries will be carried out to comply with the conditions provided in the licence or aggregate permit, if a licence or aggregate permit exists or is required; and
- Blasting delays and blast mats will be used, as appropriate, to control vibration and fly rock as required.

9.5.3.3.2.3 Predicted Residual Effects

Vibration during construction may result in a potential effect because it is predicted that, after the implementation of impact management measures, exceedances of applicable criteria at potential points of reception may occur. This potential effect is therefore carried through for further assessment in the following sections, including an assessment of significance.

9.5.3.4 Residual Effects – Operations Phase

9.5.3.4.1 Changes to Noise Levels

9.5.3.4.1.1 Potential Effects

Noise levels can be expected to increase during operations due to road traffic and maintenance activities. Noise levels due to maintenance activities at the potential points of reception are expected to be similar to (or lower than) construction noise levels, temporary in nature and localized within the Local Study Area. Therefore, noise levels due to maintenance during Operations are bounded by those assessed for Project Construction and are not further assessed.

Table 9.5-11 and **Figure 9.5-9** and **Figure 9.5-10** present the predicted noise levels from road traffic during Project operations at the potential points of reception. **Table 9.5-12** presents the predicted noise levels from the pit and quarry operations at those locations which will operate during Project operations (**Figure 9.5-4**). The following tables also indicate the applicable noise limit for each parameter and indicates where noise levels exceed these limits in bold / underline. Note, the criteria related to the nighttime L_{max} to address potential sleep disturbance was not further assessed as the road traffic noise prediction algorithm does not predict this parameter. For the purposes of this assessment, sleep disturbance was assessed considering the Health Canada criteria L_n.

The range in increased noise levels associated with operations will depend primarily on the distance from the Community Access Road or pit and quarry to the points of reception (in other words, the Project noise levels in the environment generally decrease as the distance between the points of reception and noise sources increases).

The results in **Table 9.5-11** and **Figure 9.5-9** and **Figure 9.5-10** indicate that for the operation of the Community Access Road, predicted noise levels were below applicable thresholds.

The results in **Table 9.5-12** indicate that for the operation of pits and quarries, at one point of reception where habitation may occur (in other words, a potential receptor as defined by NPC-300), the predicted daytime noise level of 46 A-weighted decibels exceeds the NPC-300 daytime sound level limit of 45 A-weighted decibels by 1 A-weighted decibels. The results also indicate that at points of reception within 100 metres of the effects assessment Construction Disturbance Area surrounding pits and quarries that are active during Project operations, predicted daytime noise levels exceed the Health Canada criteria of 55 A-weighted decibels for good speech comprehension. Note that no potential habitation locations were identified within 100 metres of the effects assessment Construction Disturbance Area.

Table 9.5-11: Summary of Predicted Noise Levels at Points of Reception During Operation – Road Use

600 to 1,000 m	4	1	42 to 52	44	43 to 52	44	1.5
1,000 to edge of Local Study Area	47	4	10 to 46	10 to 30	38 to 47	41 to 41	0.0 to 0.1

Footnotes: **Bold** indicates exceedance of applicable noise limit
(a) Land uses where habitation (in other words, sleep) is not expected to occur included recreation, animal, fish and plant harvest, and cultural, spiritual, and sacred.
(b) Locations where habitation may occur included outfitter camps and locations identified as habitation through Indigenous Knowledge.
(c) Daytime is defined as 7 a.m. to 10 p.m.
(d) Day-night noise level and percent highly annoyed criteria are only applicable for points of reception where habitation may occur.
(e) As quarry operations are expected to occur during the daytime only, the existing nighttime noise level of 33 A-weighted decibels was used to calculate the day-night noise level.

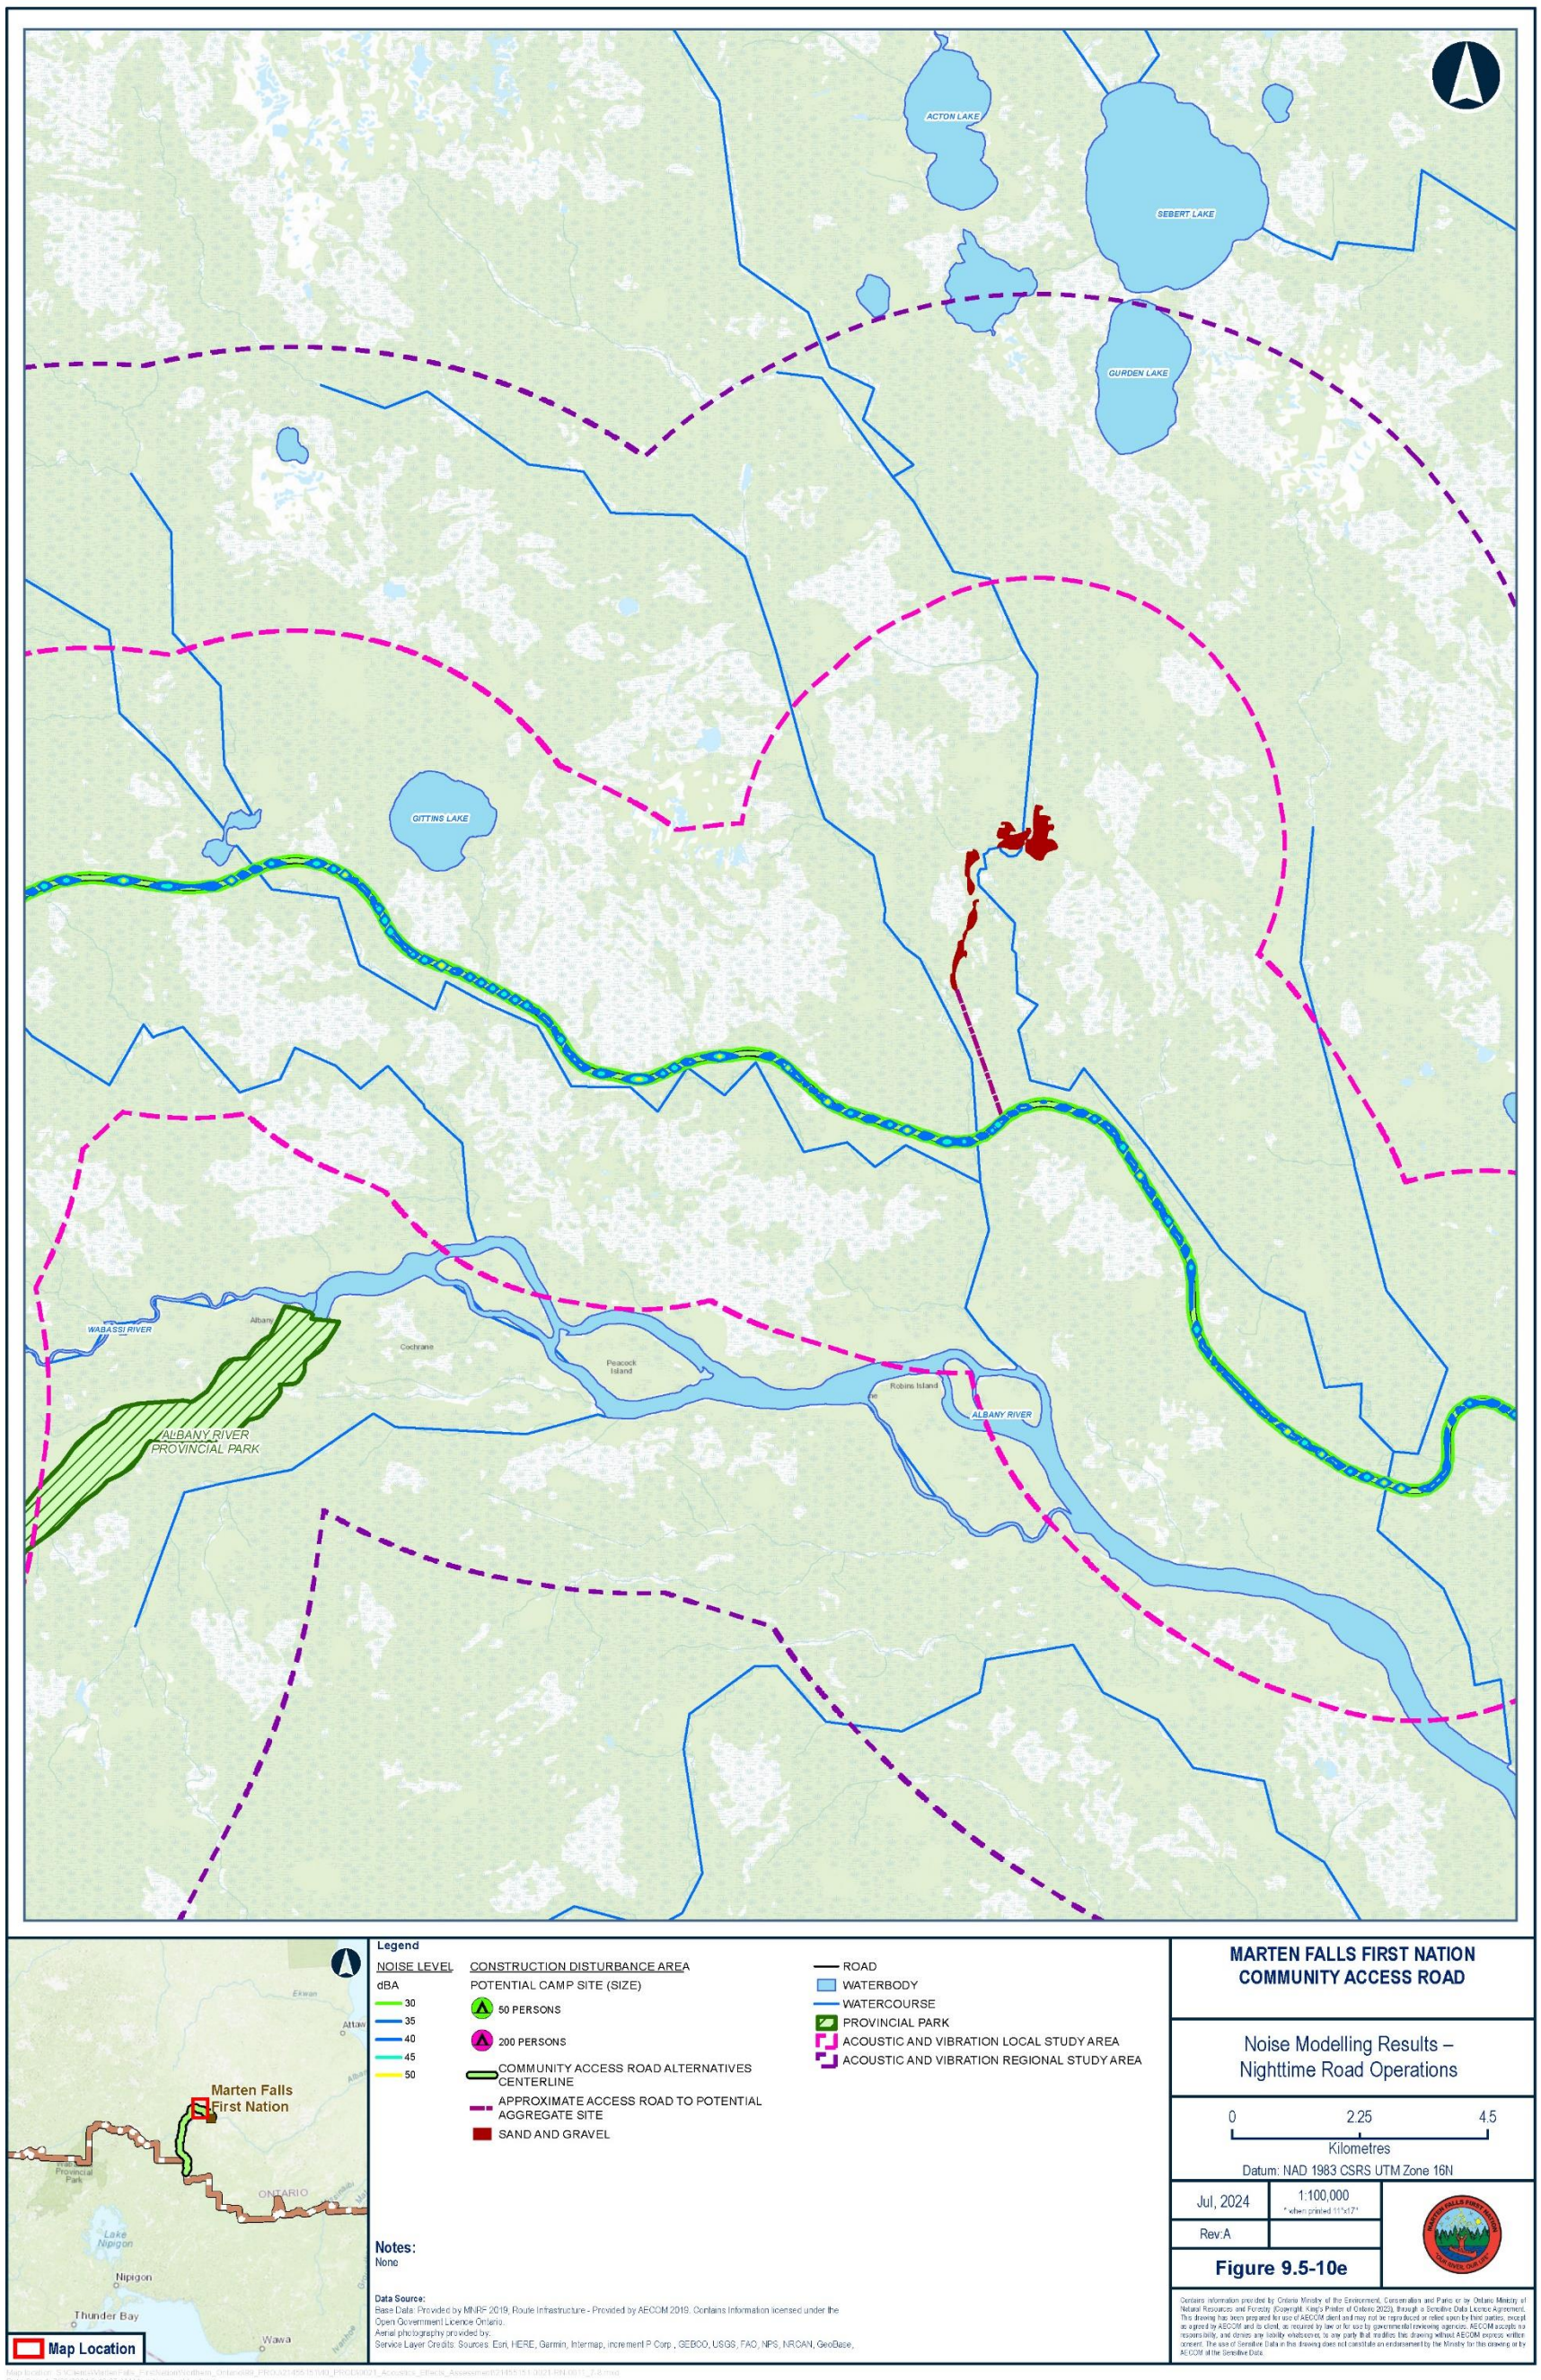

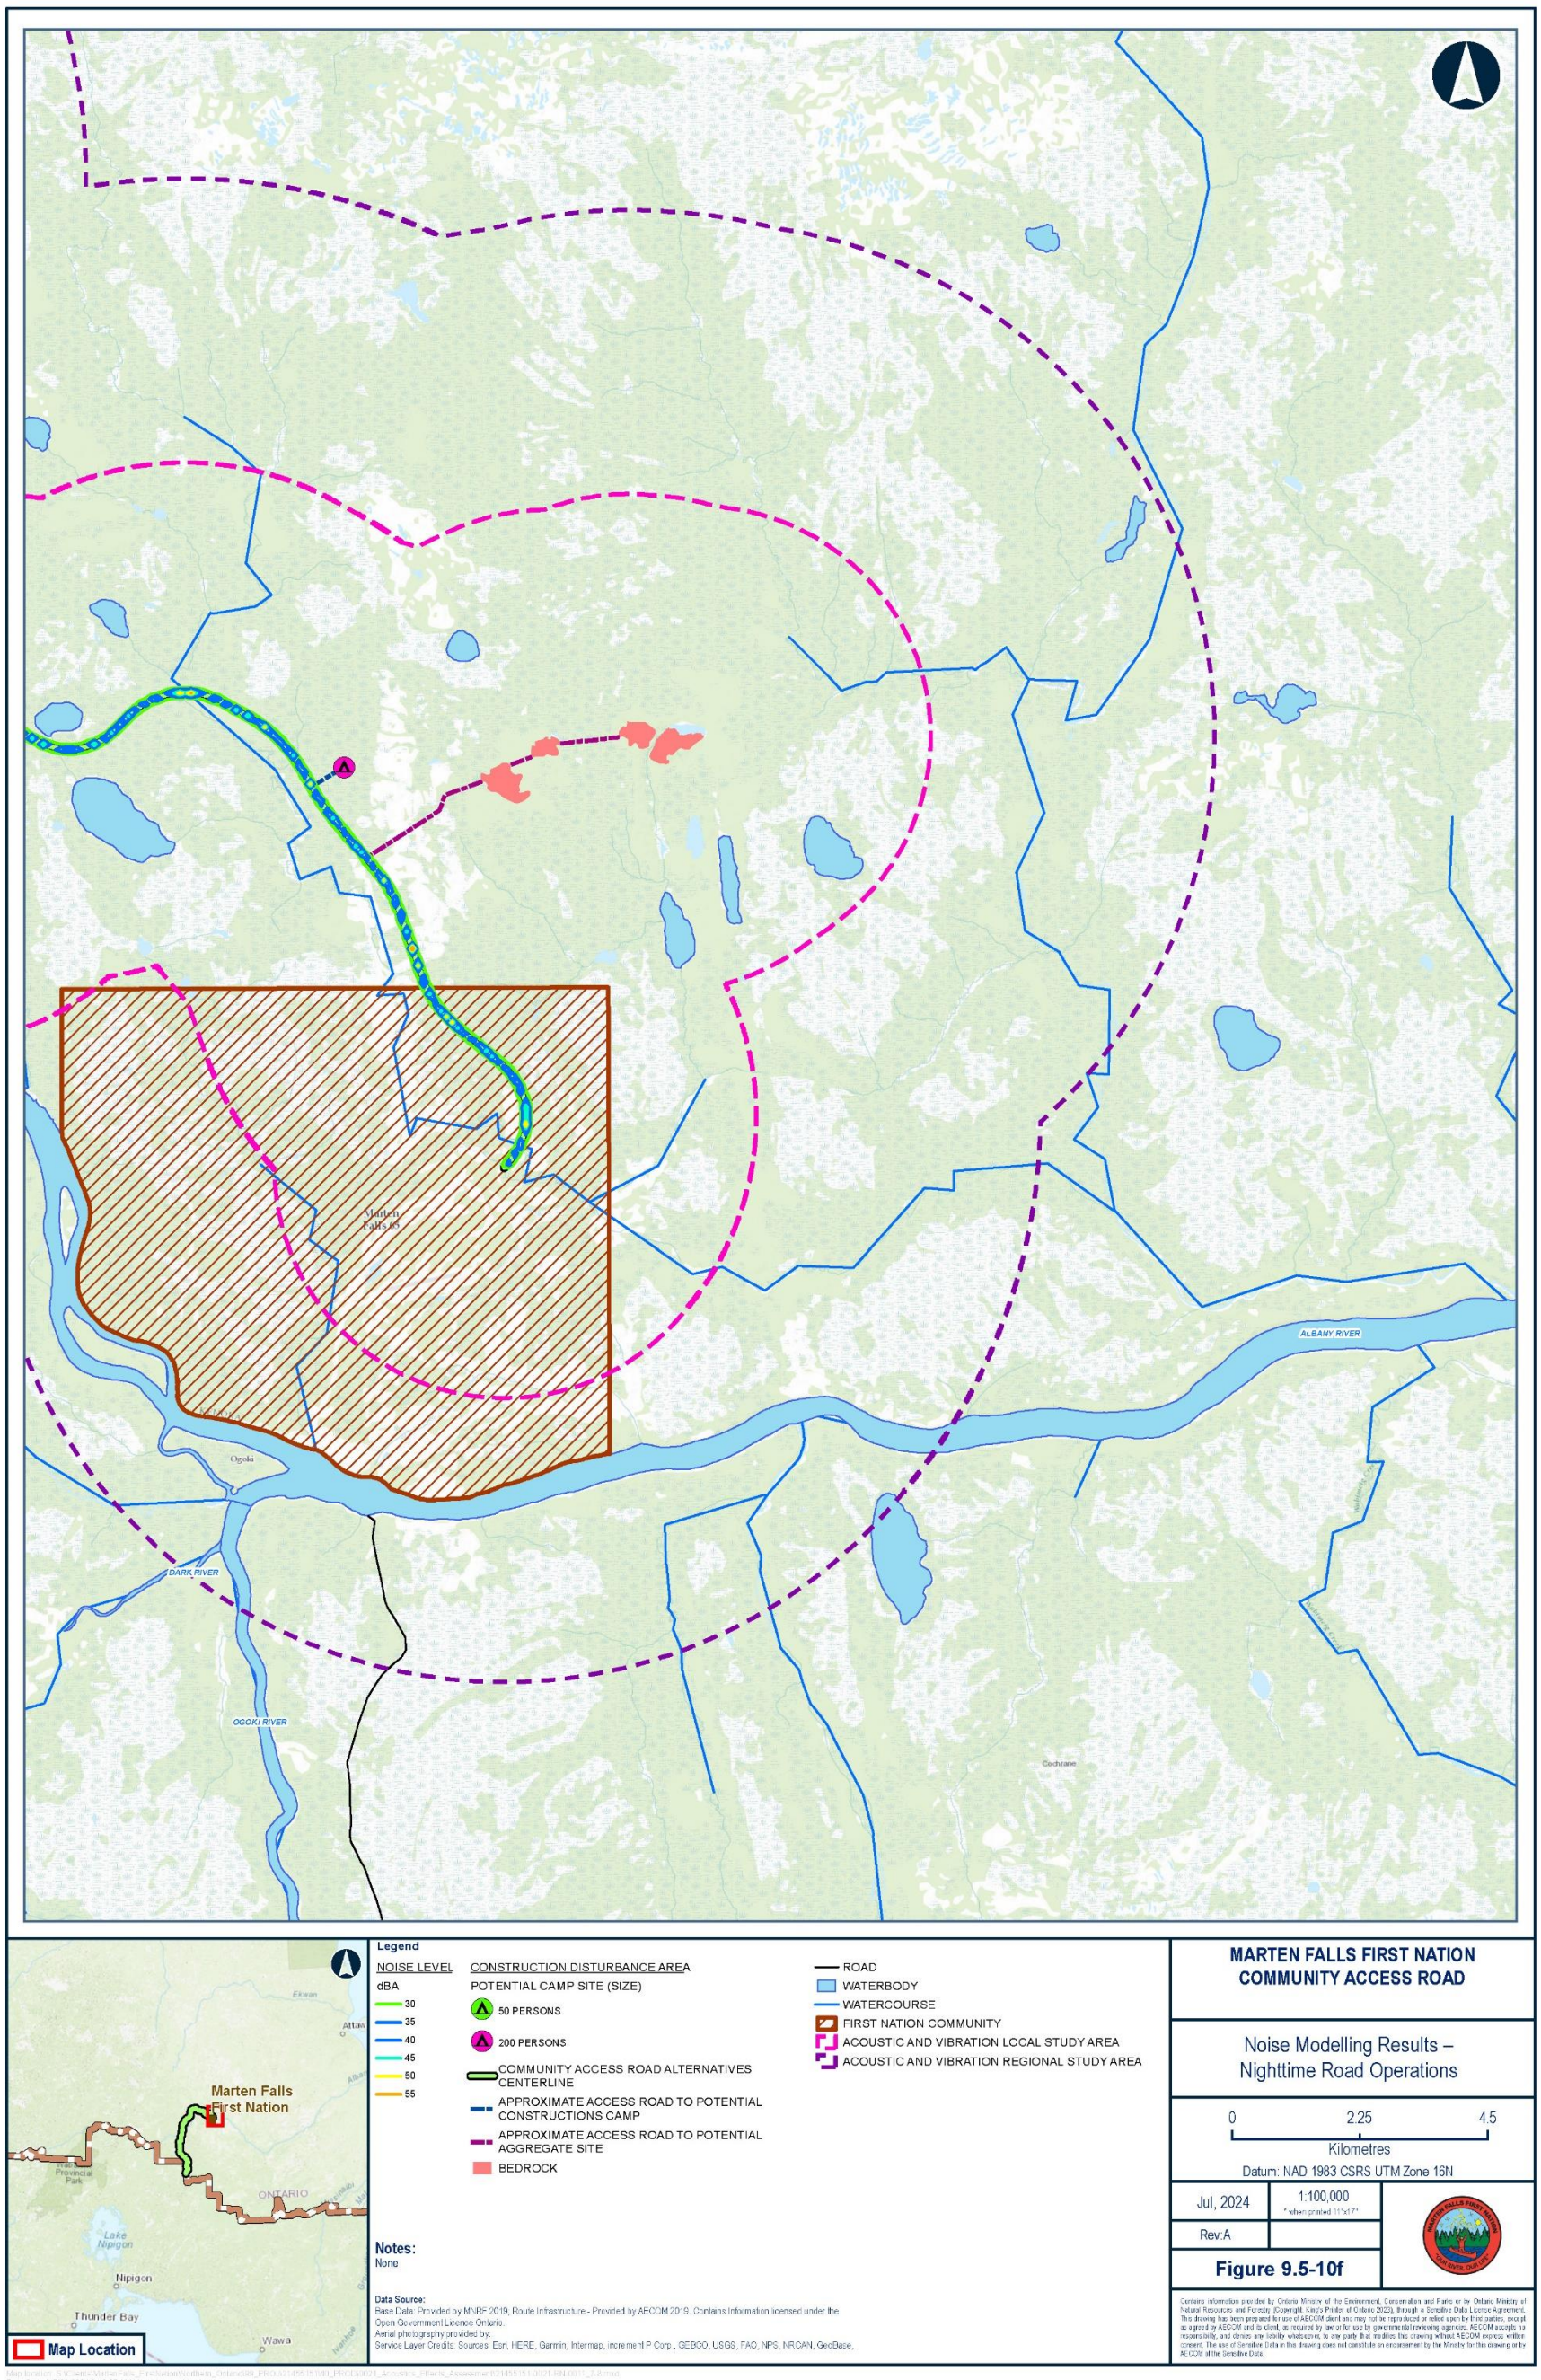

Figure 9.5-10f: Noise Modelling Results – Nighttime Road Operations

It is expected that the pits and quarries that continue operating during Project operations will require a permit / licence application for aggregate extraction under other municipal and / or provincial jurisdictions (in other words, Ministry of the Environment, Conservation and Parks and Ministry of Natural Resources). This permitting process is expected to include a quantitative noise assessment for each quarry in accordance with NPC-300. As part of these noise assessments, it is expected that the points of reception in the vicinity of the quarries and the equipment operating at the quarries will be refined, and noise mitigation requirements will be determined if needed. It is expected that, through this process, the noise assessments will demonstrate that the quarries comply with the applicable NPC-300 sound level limits.

9.5.3.4.1.2 Mitigation and Enhancement Measures

It is expected that it will be demonstrated through the permitting process that noise levels from the pits and quarries comply with the applicable NPC-300 sound level limits. If required, mitigation measures will be determined during the permitting process.

9.5.3.4.1.3 Predicted Residual Effects

Noise emissions during operations may result in a potential effect because it is predicted that, after the implementation of impact management measures, exceedances of applicable criteria at potential points of reception within 100 metres of an active pit and quarry may occur. This potential effect is therefore carried through for further assessment in the following sections, including an assessment of significance.

9.5.3.4.2 Changes to Vibration Level

9.5.3.4.2.1 Potential Effects

The vibrations induced by vehicle traffic due to the operation of the Community Access Road (in other words from road traffic) were estimated to meet the human annoyance criteria beyond 25 metres of the edge of the Community Access Road (in other words, approximately 31 metres from the Community Access Road centreline). The City of Toronto Bylaw 514-2008 preliminary zone of influence criteria (such as, 5 millimetres per second) for building damage is expected to be within the edges of the road when assuming a crest factor of 4 to estimate peak particle velocity vibration levels due to the operation of the Community Access Road (in other words, from road traffic).

The existing vibration levels due to quarry blasting activities can be expected to increase, on occasion, at nearby points of reception, but blast-induced vibration is expected to be temporary in nature, occur only during specific activities, and limited to the vicinity of the Project footprint within the Study Area. The range in increased vibration levels associated with blasting during operations will depend primarily on the

maximum explosive weight detonated at any given instance and the proximity to the points of reception (in other words, the Project vibration levels in the environment generally decrease as the distance between the point of reception and maximum charge weight detonated at a given instance [in other words, delay period]).

9.5.3.4.2.2 Mitigation and Enhancement Measures

No mitigation is expected for vibration from the vehicle traffic along the road due to the operation of the Community Access Road.

Mitigation measures that relate to blasting will be carried forward from construction to the quarry blasting that occurs during operations.

9.5.3.4.2.3 Predicted Residual Effects

Vehicle use on the road due to the operation of the Community Access Road has not been carried forward for further assessment as no residual effect is expected.

Vibration during operations from quarry blasting may result in a potential effect because it is predicted that, after the implementation of impact management measures, exceedances of applicable criteria at potential points of reception may occur. This potential effect is therefore carried through for further assessment in the following sections, including an assessment of significance.

9.5.3.5 Summary of Residual Effects

Table 9.5-13 provides a summary of the potential effects for acoustic environment, mitigation measures, and residual effects. Detailed information is included in **Appendix P**.

Table 9.5-13:Summary of Residual Effects for Acoustic Environment

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Noise**	• Clearing, grading, earth moving, grubbing of vegetation, and stockpiling of materials along the right-of-way and other access and construction areas, and construction of infrastructure (for example, access roads, bridges, temporary laydown areas, turn-around areas, and temporary construction camps) • Reclamation and decommissioning of access roads, temporary laydown areas, staging areas and construction camps • Use of pits and quarries	• Construction	• Construction activities may result in an increase in noise levels	• Conduct construction activities during the daytime period (7 a.m. to 7 p.m.). Nighttime work is not anticipated. In the event construction will occur beyond the daytime period, applicable mitigation measures will be reviewed and implemented as required. • Check that equipment and machinery used on site is maintained in good working conditions through regular maintenance and inspection. • Design access roads to minimize reversing, which is expected to minimize use of backup beepers, where possible. • Locate and operate construction equipment as far as possible from points of reception. • Engage with Indigenous communities and relevant stakeholders to coordinate the planned construction schedule before the start of construction and prior to specific noisy activities to minimize overlap with the timing of traditional land use activities (for example, fall and spring hunting seasons). • Where reasonable and practicable, turn off vehicles and equipment when idle, unless weather and / or safety conditions dictate the need for them to remain turned on and in a safe operating condition. • Investigate noise concerns as they arise through a complaint resolution mechanism developed by the owner / operator whereby persons can contact the Project team if there are perceived noise issues. • Operate vehicles and equipment to minimize impulsive noise, where possible.	• Net change in noise levels during construction activities	• Context: Ecological, Social • Direction: Negative • Magnitude: High • Geographic Extent: Local • Duration: Short term • Frequency: Infrequent • Reversibility: Reversible • Probability: Certain • Significance: Not significant • Uncertainty: Moderate • Direct / Indirect: Direct
• **Noise**	• Operations of the right-of-way, fencing, and permanent access roads • Use of pits and quarries	• Operations	• Operations activities may result in an increase in noise levels	• Maintain the surface of the road such that rough surface conditions are avoided. • Operate pits and quarries in accordance with NPC-300 and applicable permitting requirements. • Conduct maintenance activities during the daytime period (7 a.m. to 7 p.m.). • Check that equipment and machinery used for site maintenance is maintained in good working conditions through regular maintenance and inspection. • Where reasonable and practicable, turn off maintenance equipment when idle, unless weather and / or safety conditions dictate the need for them to remain turned on and in a safe operating condition. • Operate maintenance equipment to minimize impulsive noise, where possible.	• Net change in noise levels during operations activities (road / quarry)	• Context: Ecological, Social • Direction: Negative • Magnitude: Low / High • Geographic Extent: Local • Duration: Long term • Frequency: Frequent / Infrequent • Reversibility: Reversible • Probability: Certain • Significance: Not significant • Uncertainty: Moderate • Direct / Indirect: Direct

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Vibration**	• Clearing, grading, earth moving, grubbing of vegetation, and stockpiling of materials along the right-of-way and other access and construction areas, and construction of infrastructure (for example, access roads, bridges, temporary laydown areas, turn-around areas, and temporary construction camps) • Reclamation and decommissioning of access roads, temporary laydown areas, staging areas and construction camps • Use of pits and quarries	• Construction	• Construction activities may result in an increase in vibration levels	• Develop a Construction Vibration Workplan prior to the start of construction describing the construction schedule, list of construction equipment, list of point of reception locations (such as, traditional land use, residential, heritage structures and utilities), applicable guidance documents including criteria and control measures. • Consider the use of frequency-dependent vibration limits as more detailed information regarding the construction activities is known. • Engage with Indigenous communities and relevant stakeholders to coordinate the planned construction schedule before the start of construction and prior to specific activities that may generate vibration to minimize overlap with the timing of traditional land use activities (for example, fall and spring hunting seasons). • Investigate vibration concerns as they arise through a complaint resolution mechanism whereby persons can contact the Project team if there are perceived vibration issues. • Construction activities should be limited to the daytime period (7 a.m. to 7 p.m.). Nighttime work is not anticipated. In the event construction will occur beyond the daytime period, applicable mitigation measures will be reviewed and implemented as required. • Locate and operate construction equipment as far as possible from points of reception. • Avoid operating equipment that is expected to generate significant vibration at the same time. Operating them separately may reduce overall vibration levels. • Construction blasting will be carried out in compliance with the General Specification for the use of Explosives (Ministry of Transportation. 2014) and NPC-119: Blasting (Ministry of the Environment, 1978). The General Specification for the use of Explosives details items such as vibration limits, protective measures, preblast surveys and notification to nearby owners and tenants. All blasts, which might impact local structures or disrupt humans, will be monitored for ground and air vibrations. • Blasting at temporary or existing quarries will be carried out to comply with the conditions provided in the licence or aggregate permit, if a licence or aggregate permit exists or is required. • Blasting delays and blast mats will be used, as appropriate, to control vibration and fly rock as required.	• Net change in vibration levels during construction activities	• Context: Ecological, Social • Direction: Negative • Magnitude: High • Geographic Extent: Local • Duration: Short term • Frequency: Infrequent • Reversibility: Reversible • Probability: Certain • Significance: Not significant • Uncertainty: Moderate • Direct / Indirect: Direct

9.5.4 Atmospheric Environment

9.5.4.1 Air Quality

9.5.4.1.1 Project-Environment Interactions

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction and Operation**	• Mobilization of equipment and supplies • Temporary construction staging areas • Temporary access roads and trails • Temporary construction camps • Right-of way clearing and grubbing • Pits and quarries • Temporary concrete batch plants • Drilling / blasting / aggregate production • Road construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and culvert installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction site restoration • Rehabilitation (progressive and final) and surrender of pits and quarries in accordance with the *Aggregate Resources Act*. • Decommissioning of temporary camps, roads / trails and staging areas	• Air Quality	• Concentration of air contaminants: • nitrogen dioxide • carbon monoxide • sulphur dioxide • Total Suspended Particulate • particulate matter less than 10 micrometres • particulate matter less than 2.5 micrometres • Selected Volatile Organic Compounds (acrolein, acetaldehyde, benzene, formaldehyde, 1,3-butadiene, toluene, ethylbenzene, and xylene) • Polycyclic aromatic hydrocarbons (benzo(a)pyrene)	• Change in concentration of air contaminants

9.5.4.1.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following air quality definitions apply to the effects assessment.

Ecological and Social Context

For the air quality assessment, ecological and social context is directly related to changes in air quality with respect to relevant air quality criteria.

Modelling was completed for the construction and operation phases of this Project. Predicted impacts from the model were combined with monitored background air quality to determine the potential effects.

The potential residual effects were assessed along the Construction Disturbance Area and at the Marten Falls First Nation community for the construction and operational scenarios. Community-specific models were developed to provide predicted impacts of road construction activities in close proximity to the Marten Falls First Nation community. Community model results were based on a worst-case operations condition assuming the worst-case emissions for each indicator compound across all construction operations / activities where all equipment and construction-related activities are occurring at the same time. This includes blasting and burning emissions. This scenario is unlikely to occur during periods of construction however it was assessed to provide the most conservative model results for the purpose of evaluating potential air quality impacts at the Marten Falls First Nation community location.

Magnitude

For magnitude, environmental discipline-specific definitions are required and are provided below in **Table 9.5-14**. Magnitude of effects are project-related and exclude variations due to climate change.

Table 9.5-14: Air Quality Magnitude Definition

Magnitude Level	Definition	Rationale
• **Negligible**	• Cumulative concentrations (Community Access Road plus background) are below air quality criteria and an increase of less than 50 percent of existing conditions values at sensitive receptors	• Magnitude definitions consider compliance with air quality criteria and changes from existing conditions (Ministry of the Environment, Conservation and Parks, 2020; Canadian Council of Ministers of the Environment, 2025)

Magnitude Level	Definition	Rationale
• Low	• Cumulative concentrations (Community Access Road plus background) are below air quality criteria and an increase of more than 50 percent of existing conditions values at sensitive receptors	• Same as previous
• Medium	• Cumulative concentrations (Community Access Road plus background) exceed air quality criteria, and an increase of less than 50 percent of existing conditions values at sensitive receptors	• Same as previous
• High	• Cumulative concentrations (Community Access Road plus background) exceed air quality criteria, and an increase of more than 50 percent of existing conditions values at sensitive receptors	• Same as previous

9.5.4.1.3 Residual Effects – Construction Phase

9.5.4.1.3.1 Potential Effects

Nitrogen Dioxide

The largest contributor to the predicted impact of hourly nitrogen dioxide emissions are quarry blasting operations. Comparing the predicted impacts against the hourly nitrogen dioxide Ambient Air Quality Criteria, no individual construction activity predicted an impact that would result in an exceedance of the 1-hour thresholds besides demonstrating an increase in background concentrations above 50 percent of the existing conditions. The largest contributor to the predicted impact of 24-hour nitrogen dioxide emissions is land clearing operations (in other words, biomass / tree burning). No activity resulted in an exceedance of the 24-hour thresholds besides demonstrating an increase in background concentrations above 50 percent of the existing conditions. Annual results were elevated above Canadian Ambient Air Quality Standards criteria.

Total Suspended Particulates

The largest contributor to the predicted impact of 24-hour Total Suspended Particulate emissions is biomass burning during Operations. Exceedances of the 24-hour thresholds (Ambient Air Quality Criteria, 50 percent of Ambient Air Quality Criteria and 50 percent of ambient background), may occur during road construction activities, access road usage to aggregates and burning operations.

No construction activity was shown to exceed any threshold for the annual averaging period with the exception of the access road. The access road was shown to exceed the

threshold for maximum distance to criteria with background removed. This threshold indicates that when effects of Project and ambient background concentrations are considered, there is the potential for exceedance of the Ambient Air Quality Criteria. The ambient Total Suspended Particulate concentrations represent 94 percent of the Ambient Air Quality Criteria.

Particulate Matter 10 micrometres or less in diameter

The largest contributor to the predicted impact of 24-hour particulate matter less than 10 micrometres emissions is biomass burning operations. Exceedances of the 24-hour thresholds (Ambient Air Quality Criteria, 50 percent of criteria, 50 percent of ambient background and criteria minus background) may occur during road construction activities, access road usage and burning operations.

Particulate Matter 2.5 micrometres or less in diameter

The largest contributor to the predicted impact of 24-hour particulate matter less than 2.5 micrometres emissions is biomass burning operations. Exceedances of the 24-hour thresholds (Ambient Air Quality Criteria, Canadian Ambient Air Quality Standards, 50 percent of criteria, 50 percent of ambient background and criteria minus background) may occur during road construction activities and burning operations.

Sulfur Dioxide

The largest contributor to the predicted impact of 10-min as well as 1-hour sulphur dioxide emissions is quarry blasting operations. With the exception of quarry blasting and road blasting, comparing the predicted impacts against both the 10-min and hourly Ambient Air Quality Criteria as well as the 1-hour Canadian Ambient Air Quality Standards, no individual construction activity predicted an impact that would result in an exceedance of either the 10-min or 1-hour thresholds except for demonstrating an increase in background concentrations above 50 percent of the existing conditions. As previously noted, the Canadian Ambient Air Quality Standards are stringent aspirational regional air quality targets and not Project-specific air quality criteria.

No activities were shown to exceed any threshold for the annual averaging period.

Carbon Monoxide

The largest contributor to the predicted impact of 1-hour and 8-hour carbon monoxide emissions is quarry blasting operations. With the exception of quarry blasting, comparing the predicted impacts against the hourly Ambient Air Quality Criteria, no individual construction activity predicted an impact that would result in an exceedance of

the 1-hour or 8-hour thresholds with except for demonstrating an increase in background concentrations above 50 percent of the existing conditions.

Acrolein

The largest contributor to the predicted impact of hourly acrolein emissions is bridge building operations. The activity associated with bridge building including fossil fuel combustion from heavy-duty construction equipment and the location of bridge building sources compared to distance to the edge of the Construction Disturbance Area (in other words, operations occurring in close proximity to the edge of the road) contribute to the maximum predicted impacts from volatile organic compounds. With the exception of bridge building, comparing the predicted impacts against the hourly Ambient Air Quality Criteria, no individual construction activity predicted an impact that would result in an exceedance of the 1-hour thresholds.

No construction activity was shown to exceed any threshold for the 24-hour averaging period with the exception of bridge building activities that demonstrating an increase in background concentrations above 50 percent of the existing conditions.

Acetaldehyde

No construction activity was shown to exceed any threshold for the 0.5-hour or 1-hour averaging periods with the exception of bridge building activities that demonstrating an increase in background concentrations above 50 percent of the existing conditions.

Benzene

No construction activity was shown to exceed any threshold for the 24-hour or annual averaging periods.

Formaldehyde

No construction activity was shown to exceed any threshold for the 24-hour averaging period.

1, 3-Butadiene

No construction activity was shown to exceed any threshold for the 24-hour or annual averaging periods.

Toluene

No construction activity was shown to exceed any threshold for the 24-hour averaging period with the exception of bridge building which demonstrated an increase in background concentrations above 50 percent of the existing conditions. The activity

associated with bridge building including fossil fuel combustion from heavy-duty construction equipment and the location of bridge building sources compared to distance to the edge of the Construction Disturbance Area (in other words, operations occurring in close proximity to the edge of the road) of operations contribute to the maximum predicted impacts from volatile organic compounds.

Ethylbenzene

No construction activity was shown to exceed any threshold for the 24-hour averaging period with the exception of burning operations which demonstrated an increase in background concentrations above 50 percent of the existing conditions.

Xylene

No construction activity was shown to exceed any threshold for the 24-hour averaging period with the exception of bridge building which demonstrated an increase in background concentrations above 50 percent of the existing conditions. The activity associated with bridge building including fossil fuel combustion from heavy-duty construction equipment and the location of bridge building sources compared to distance to the edge of the Construction Disturbance Area (in other words, operations occurring in close proximity to the edge of the road) of operations contribute to the maximum predicted impacts.

Benzo(a)Pyrene

The largest contributor to the predicted impact of 24-hour Benzo(a)Pyrene emissions is bridge building operations. The activity associated with bridge building including fossil fuel combustion from heavy-duty construction equipment and the location of bridge building sources compared to distance to the edge of the Construction Disturbance Area (in other words, operations occurring in close proximity to the edge of the road) contribute to the maximum predicted impacts from volatile organic compounds. With the exception of bridge building, comparing the predicted impacts against the 24-hour Ambient Air Quality Criteria, no individual construction activity predicted an impact that would result in an exceedance of the 24-hour thresholds with except for demonstrating an increase in background concentrations above 50 percent of the existing conditions.

No individual construction activity predicted an impact that would result in an exceedance of the annual thresholds with except for demonstrating an increase in background concentrations above 50 percent of the existing conditions.

Diesel Particulate Matter

Diesel Particulate Matter emissions are generated from tailpipe emissions of diesel-fired combustion equipment. To provide a conservative estimate of Diesel Particulate Matter emissions, it is assumed that they are equal tailpipe emissions of particulate matter less than 2.5 micrometres.

There are currently no Ontario Ambient Air Quality Criteria to evaluate the predicted impact of Diesel Particulate Matter emissions.

The maximum 24 hour and annual Diesel Particulate Matter concentrations during construction are 15.1 micrograms per cubic metre and 2.0 micrograms per cubic metre respectively. The maximum concentrations of Diesel Particulate Matter occur in close proximity to diesel-fired heavy construction equipment.

Dustfall

Model results indicate that predicted dustfall loadings that are above annual criteria during road construction at some receptors. Contour plots indicate that the predominate contributing source modelled is the quarry access road. The dustfall loading is expected to be influenced by fugitive dust generated by haul trucks transporting aggregate material from quarries on an unpaved access road. Dustfall levels were modelled to be elevated above annual criteria up to approximately 280 metres from the edge of the road.

Model results do not predict elevated dustfall loadings greater than the 30-day criteria during construction activities.

Table 9.5-15 and **Table 9.5-16** present the maximum predicted ground level concentration of each indictor compound without the removal of meteorological anomalies or mitigation. Results are included for both a maximum construction scenario (in other words, equipment and activities operations at the same time, this would include blasting operations occurring at the same time of other activities) as well as a summary of modelled maximum ground level concentrations on an individual activity basis. Where exceedances to criteria were not present or indicator compounds were not released as part of an individual activity's emissions (such as, benzene emissions during quarry blasting) maximum ground level concentrations are not provided.

Table 9.5-15: Summary of Maximum Point of Impingement Results - Construction North-South Segment

Indicator Compound	Averaging Period	Criteria (micrograms per cubic metre)	Guideline	Basis	Ambient (micrograms per cubic metre)	Maximum Point of Impingement (micrograms per cubic metre)	Percent Criteria (Project Only)	Percent Criteria (Project plus Background)

Footnotes: Maximum Point of Impingement results occur immediately adjacent to construction activities.
10-min averaging periods were converted from 1-hr results.
Not applicable indicates not applicable.
Bold values were converted from ppb.

9.5.4.1.3.2 Mitigation and Enhancement Measures

Mitigative measure such as the implementation of strategic blasting plans and efforts to utilize low sulphur containing explosives can help reduce the magnitude of effect during blasting events.

Restricting access to construction areas can be implemented to help limit human exposure to the reported maximum ground level concentrations of indicator compounds predicted adjacent to construction operations.

Development of a construction best management practice plan as well as a fugitive dust management plan prior to construction. Examples of best management practices that may be included are:

- Implement watering during fugitive dust-generating activities such as drilling, material handling and on quarry access roads;
- Limit vehicle speed, where feasible;
- Strategic haul planning to reduce overall number of haul trips required for aggregate material demands. Consider sourcing material from the closest available material transfer points;
- Where possible, reduce the quantity of material that is either burned or chipped (in other words, consider salvageable material such as salable lumber);
- When burning is required, consider avoiding periods where meteorological conditions (for example, wind speed) that may result in smoke impacting sensitive receptor locations;
- Maintain equipment as per manufacturing specifications;
- Implement anti-idling policies or procedures to reduce total vehicle idling times;
- Implement blasting mitigation (for example, charge size) in quarries to minimize potential effects;
- Consider the use explosives with lower sulphur content where possible;
- Use explosives only if alternate methods of excavation to remove materials for foundation systems and roads are not feasible; and
- Prepare a Blasting and Communication Management Plan that is in accordance with Ontario Provincial Standard Specification General Specifications for the Use of Explosives (OPSS, 2014) and describes specific measures that would be implemented if blasting is required.

- Development of a Construction Monitoring Plan. This plan may be used to validate that best management practices are being implemented and that mitigation actions taken are effective. Where mitigation is not providing a reduction to overall impacts, mitigation options should be re-assessed.

9.5.4.1.3.3 Predicted Residual Effects

The predicted impacts of indicator compounds from the representative segment air dispersion model were used for the characterization of residual effects and determination of significance. The predicted impacts at the representative segment are assumed to be extrapolated across the entire Construction Disturbance Area.

The majority of the Construction Disturbance Area is located in areas where prolonged human presence is not anticipated. It should also be noted that due to the transient nature of construction activities (in other words, major construction activities will be short-term at any given location as road development continues), the predicted impacts may be considered temporary in nature.

Construction occurs in a short-term duration and is transient in nature. Construction at any location of the road is only expected for a short period of time before the next section of road is worked on. After periods of construction are completed, elevated levels of indicator compounds contributed by construction-related activities should return to previous conditions. It is expected that residual effects with a high magnitude will occur during construction periods and may impact sensitive receptors for periods of times when construction activities are either located in close proximity to receptors, or during periods of intermittent activities such as blasting and burning.

The dispersion modelling assessment was prepared using conservative emission rates and modelling parameters to present a worst-case impact predicted result. Therefore, the predicted impact is not likely to be exceeded.

The likelihood of effects would range from possible to probable. The likelihood for residual effects were considered probable for indicator compounds assessed with annual averaging periods. It is possible that construction activities will not affect some receptors for an entire year, the annual prediction is therefore conservative. The residual effects presented for annual averaging periods is less likely to be impacted by anomalous meteorological conditions and worst-case activity operations hours. For indicator compounds assessed with shorter averaging periods the likelihood for residual effects was determined to be possible to probable.

The uncertainty of effects is contributed to conservatism is built into the emission rate calculations and dispersion modelling assessment to where the maximum emission

rates and modelling results are presented. The predicted impacts from construction activities presented are not likely to be exceeded.

Uncertainty of receptor characteristics, such as frequency of human presence at receptor locations are also present within this assessment. Sensitive receptors considered as part of this significance assessment included those where human presence is expected for a potentially long duration in time. In the event that humans are not at sensitive receptor locations during constructions the significance of effects is further reduced. For example, spiritual and sacred sites were considered as sensitive receptors however if humans are not present at these locations, particularly those in close proximity to the road or quarry locations during periods of intermittent and consistent construction activities, residual effects could be avoided.

Prediction confidence of effects was determined to be moderate. Representative baseline data was known for receptor locations, potential for Project related effects are mostly understood, and the level of uncertainty associated with receptor data or Project conditions is moderate.

9.5.4.1.4 Residual Effects – Operations Phase

9.5.4.1.4.1 Potential Effects

Nitrogen Dioxide

Along the north-south road segment predicted impacts of NO_2 (Project-only and Project plus background air quality) are not expected to exceed the criteria for either 1-hour, 24-hour or annual averaging periods. Along the east-west road segment predicted impacts of nitrogen dioxide (Project-only and Project plus background air quality) are not expected to exceed nitrogen dioxide criteria for either 1-hour, 24-hour, or annual averaging periods. None of the thresholds developed to assess potential effects were exceeded (in other words, criteria, 50 percent of criteria, 50 percent of background, criteria minus background).

Total Suspended Particulates

Along the north-south road segment the maximum predicted impact of Total Suspended Particulate (Project-only) are expected to exceed Total Suspended Particulate criteria for both 24-hour and annual averaging periods. Total Suspended Particulate 24-hour and annual impacts are predicted to exceed criteria 3,000 metres and 899 metres from the road, respectively. The impact of Total Suspended Particulate with background concentrations added to Community Access Road impacts extended outside of the modelling domain (3,000 metres from the Construction Disturbance Area).

Maximum ground level concentrations of Total Suspended Particulate (Project-only) are expected to exceed 50 percent of 24-hour and annual criteria greater than 3,000 metres and up to 1,591 metres from the edge of the road, respectively.

Along the east to west road segment maximum predicted impacts of Total Suspended Particulate are expected to exceed Total Suspended Particulate criteria for the 24-hour averaging period. Maximum ground level concentrations are expected to exceed or equal 24-hour criteria up to 119 metres from the road. When impacts of background ambient air quality are considered in addition to Project impacts, this distance is extended to 1,001 metres. Maximum predicted impacts are expected to exceed or be equal to 50 percent of 24-hour criteria up to 436 metres.

Exceedances to annual criteria are not expected from Project contributions only, however when background ambient conditions are in addition to Project impacts, the annual criteria is expected to exceed up to 639 metres from the road. Fifty percent of the value of annual criteria is expected to be exceeded up to 27 metres without the contribution of ambient background.

It should be noted that background concentrations of Total Suspended Particulate are relatively high and account for more than 70 percent of both 24-hour and annual criteria. Background concentrations of Total Suspended Particulate will vary seasonally due to the presence of forest fires.

Fugitive road dust emissions from vehicular travel on an unpaved road will be the leading contributor to ground level concentrations of Total Suspended Particulate during operations of Community Access Road. Model results were presented without the effects of mitigation. Pending on mitigation methods applied up to an 80 percent control efficiency may be achieved.

Particulate Matter 10 micrometres or less in diameter

Along the north-south road segment maximum predicted impacts of particulate matter less than 10 micrometres are expected to exceed particulate matter less than 10 micrometres 24-hour criteria. During the operations phases of Community Access Road, maximum ground level concentrations of particulate matter less than 10 micrometres are expected to exceed or be equal to particulate matter less than 10 micrometres criteria up to 1,986 metres from the road. When considering the impacts of background concentrations in addition to Project impacts this distance is extended to 2,987 metres from the road.

Maximum predicted impacts are expected to exceed or be equal to 50 percent of 24-hour criteria up to 2,987 metres without the contribution of ambient background.

Along the east to west road segment maximum predicted impacts of particulate matter less than 10 micrometres are expected to exceed particulate matter less than 10 micrometres 24-hour averaging criteria. Maximum ground level concentrations are expected to exceed or equal 24-hour criteria up to 50 metres from the road. When impacts of background ambient air quality are considered in addition to Project impacts, this distance is extended to 375 metres.

Maximum predicted impacts are expected to exceed or be equal to 50 percent of 24-hour criteria up to 224 metres without the contribution of ambient background.

It should be noted that background concentrations of particulate matter less than 10 micrometres are relatively high and account for greater than 60 percent of 24-hour criteria. Background concentrations of particulate matter less than 10 micrometres may be overstated because of the location of the monitoring station at the community and will also vary seasonally due to the presence of forest fires.

Fugitive road dust emissions from vehicular travel on an unpaved road will be the leading contributor to ground level concentrations of particulate matter less than 10 micrometres during operations of Community Access Road.

Particulate Matter 2.5 micrometres or less in diameter

Along the north-south road segment maximum predicted impacts of particulate matter less than 2.5 micrometres are expected to exceed particulate matter less than 2.5 micrometres 24-hour and annual criteria. During the operations phases of Community Access Road, maximum ground level concentrations of particulate matter less than 2.5 micrometres are expected to exceed or be equal to particulate matter less than 10 micrometres criteria up to 115 metres and 134 metres from the road for 24-hour and annual criteria respectively. When considering impacts of background concentrations of particulate matter less than 2.5 micrometres in addition to Project impacts this distance is extended to 207 metres and 414 metres for 24-hour and annual criteria respectively.

Maximum predicted impacts are expected to exceed or be equal to 50 percent of 24-hr and annual criteria up to 433 metres and 336 metres respectively, without the contribution of ambient background.

Along the east to west road segment maximum predicted impacts of particulate matter less than 2.5 micrometres are not expected to exceed particulate matter less than 2.5 micrometres 24-hour or annual averaging criteria. Exceedances are also not expected when impacts of background ambient air quality are considered in addition to Project impacts.

Maximum predicted impacts are not expected to exceed or be equal to 50 percent of 24-hour criteria without the contribution of ambient background.

The maximum distance to 50 percent of 24-hour background conditions is 92 metres from the road.

Fugitive road dust emissions from vehicular travel on an unpaved road will be the leading contributor to ground level concentrations of particulate matter less than 2.5 micrometres during operations of Community Access Road.

Diesel Particulate Matter

Diesel Particulate Matter emissions are generated from tailpipe emissions of diesel-fired combustion equipment. To provide a conservative estimate of Diesel Particulate Matter emissions, it is assumed that they are equal tailpipe emissions of particulate matter less than 2.5 micrometres.

There are currently no Ontario Ambient Air Quality Criteria to evaluate the predicted impact of Diesel Particulate Matter emissions.

Dustfall

Model results indicate that predicted dustfall loadings are above the 30-day and annual criteria at some receptors during operations of the road along the North/South section (**Table 9.5-17**).

The predicted exceedances of 30-day criteria are expected to occur up to an approximate maximum distance of 45 metres from the edge of the road. The predicted exceedances of annual criteria are expected to occur up to an approximate maximum distance of 681 metres from the edge of the road. Background ambient dustfall was assumed to be zero due to data unavailability.

Model results indicate that predicted dustfall loadings are above the annual criteria at some receptors during operations of the road along the Community Road Segment. No exceedances of the 30-day criteria were predicted.

The predicted exceedances of annual criteria are expected to occur up to an approximate maximum distance of 28 metres from the edge of the road.

9.5.4.1.4.2 Mitigation and Enhancement Measures

Development of a best management plan for fugitive dust prior to operation phase of Community Access Road. Examples of best management practices that may be included are:

- Implement watering or application of Ontario Ministry of Transportation approved dust suppressants that are environmentally friendly; and
- Keep vegetation such as grasses shrubs and trees along the highway to enhance gravitational deposition of particles and natural windbreaks. Specifics to this are documented in the Rehabilitation Plan.

Consideration of input gathered through other technical monitoring programs specific to potential air quality concerns (in other words, potential dust deposition on vegetation) is completed and evaluated for consideration of future mitigation or monitoring options.

9.5.4.1.4.3 Predicted Residual Effects

Traffic volume and vehicle fleet composition vary between the north-south segment and Community segment resulting in different residual effects characterization between the road networks. The north-south segment towards the Ring of Fire will have seven times higher traffic volume than the east-west segment. The majority of traffic on the north-south segment towards the Ring of Fire will be heavy trucks and the majority of traffic on the east-west segment to Marten Falls community will be auto traffic.

The majority of Community Access Road spatial and geographic extent where potential air quality impacts may be expected are in areas where prolonged human presence is not anticipated. Effects characterization presented in this report reflects that of a worst-case predicted impact condition. The maximum vehicular traffic volume Projected on the road is anticipated to occur in 2046. This worst-case operations condition was used to characterize residual effects as well as determine significance.

Sensitive receptors considered as part of this significance assessment included those where human presence is expected for a potentially long duration in time. In the event that humans are not at sensitive receptor locations for periods of time less than indicator compound specific criteria averaging periods the significance of residual effects is reduced. For example, sensitive receptor exceedances to annual Total Suspended Particulate criteria may not occur if human presence at a particular receptor is limited to periods of less than one year at a time.

The dispersion modelling assessment was prepared using conservative emission rates and modelling parameters to present a worst-case impact predicted result. The

likelihood for residual effects were considered probable for indicator compounds assessed with annual averaging periods. The residual effects presented for annual averaging periods is less likely to be impacted by anomalous meteorological conditions and worst-case activity operations hours. For indicator compounds assessed with shorter averaging periods the likelihood for residual effects was determined to be possible to probable.

Uncertainty of receptor characteristics, such as frequency of human presence at receptor locations are also present within this assessment. Sensitive receptors considered as part of this significance assessment included those where human presence is expected for a potentially long duration in time. Unknown details of human presence at sensitive receptor locations adds to uncertainty in the residual impact assessment.

Prediction confidence of effects was determined to be moderate. Representative baseline data was known for receptor locations, potential for Project related effects are mostly understood, and the level of uncertainty associated with receptor data or Project conditions is moderate.

Residual effects were generally considered as significant if the residual effect was assessed at a high magnitude with potential residual impacts occurring at sensitive receptors, at either a frequent occurrence or in long term duration with irreversible effects. As operations phases of Community Access Road are not planned to end all residual effects are considered irreversible. Residual effects from operation that were classified to have a high magnitude were determined to be significant.

9.5.4.1.5 Summary of Residual Effects

Table 9.5-19 provides a summary of the potential effects for air quality, mitigation measures, and residual effects. Detailed information is included in **Appendix S**.

Table 9.5-19: Summary of Residual Effects for Atmospheric Environment

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Air Quality**	• Quarry Blasing	• Construction	• Nitrogen dioxide - Quarry Blasting	• Development of a construction best management practice plan as well as a fugitive dust management plan prior to construction. Examples of best management practices that may be included are: – Implement watering during fugitive dust-generating activities such as drilling and material handling – Limit vehicle speed, where feasible – Strategic haul planning to reduce overall number of haul trips required for aggregate material demands. Consider sourcing material from the closest available material transfer points – Where possible, reduce the quantity of material that is either burned or chipped (in other words, consider salvageable material such as salable lumber) – When burning is required, consider avoiding periods where meteorological conditions (for example wind speed) that may result in smoke impacting sensitive receptor locations – Maintain equipment as per manufacturing specifications – Implement anti-idling policies or procedures to reduce total vehicle idling times – Implement blasting mitigation (for example charge size) in quarries to minimize potential effects – Use explosives only if alternate methods of excavation to remove materials for foundation systems and roads are not feasible – Prepare a Blasting and Communication Management Plan that is in accordance with Ontario Provincial Standard Specification General Specifications for the Use of Explosives (Ontario Provincial Standard Specifications, 2014) and describes specific measures that would be implemented if blasting is required. • Development of a construction monitoring plan. This plan may be used to validate that best management practices are being implemented and that mitigation actions taken are effective. Where mitigation is not providing a reduction to overall impacts, mitigation options should be re-assessed.	• Residual changes to air quality	• Context: Ecological, Social • Magnitude: High • Direction: Negative • Geographic Extent: Not Applicable • Duration: Short-Term • Frequency: Infrequent • Reversibility: Reversible • Probability: Possible to Probable • Significance: Not Significant • Prediction Confidence: Moderate • Direct / Indirect: Direct
• **Air Quality**	• Quarry Aggregate Operations	• Construction	• Nitrogen dioxide - Quarry Aggregate Operations	• Development of a construction best management practice plan as well as a fugitive dust management plan prior to construction. • **Air Quality**	• Bridge Building	• Construction	• Sulphur Dioxide - Bridge Building	• Development of a construction best management practice plan as well as a fugitive dust management plan prior to construction. Examples of best management practices that may be included are: – Implement watering during fugitive dust-generating activities such as drilling and material handling – Limit vehicle speed, where feasible – Strategic haul planning to reduce overall number of haul trips required for aggregate material demands. Consider sourcing material from the closest available material transfer points – Where possible, reduce the quantity of material that is either burned or chipped (in other words, consider salvageable material such as salable lumber) – When burning is required, consider avoiding periods where meteorological conditions (for example wind speed) that may result in smoke impacting sensitive receptor locations – Maintain equipment as per manufacturing specifications – Implement anti-idling policies or procedures to reduce total vehicle idling times – Implement blasting mitigation (for example charge size) in quarries to minimize potential effects – Use explosives only if alternate methods of excavation to remove materials for foundation systems and roads are not feasible – Prepare a Blasting and Communication Management Plan that is in accordance with Ontario Provincial Standard Specification General Specifications for the Use of Explosives (Ontario Provincial Standard Specifications, 2014) and describes specific measures that would be implemented if blasting is required. • Development of a construction monitoring plan. This plan may be used to validate that best management practices are being implemented and that mitigation actions taken are effective. Where mitigation is not providing a reduction to overall impacts, mitigation options should be re-assessed.	• Residual changes to air quality	• Context: Ecological, Social • Magnitude: Low • Direction: Negative • Geographic Extent: 19 metres • Duration: Short-Term • Frequency: Continuous • Reversibility: Reversible • Probability: Possible to Probable • Significance: Not Significant • Prediction Confidence: Moderate • Direct / Indirect: Direct

• **Air Quality**	• Blasting, Burning	• Construction	• Formaldehyde - Blasting, Burning	• Development of a construction best management practice plan as well as a fugitive dust management plan prior to construction. Examples of best management practices that may be included are: – Implement watering during fugitive dust-generating activities such as drilling and material handling – Limit vehicle speed, where feasible – Strategic haul planning to reduce overall number of haul trips required for aggregate material demands. Consider sourcing material from the closest available material transfer points – Where possible, reduce the quantity of material that is either burned or chipped (in other words, consider salvageable material such as salable lumber) – When burning is required, consider avoiding periods where meteorological conditions (for example wind speed) that may result in smoke impacting sensitive receptor locations – Maintain equipment as per manufacturing specifications – Implement anti-idling policies or procedures to reduce total vehicle idling times – Implement blasting mitigation (for example charge size) in quarries to minimize potential effects – Use explosives only if alternate methods of excavation to remove materials for foundation systems and roads are not feasible – Prepare a Blasting and Communication Management Plan that is in accordance with Ontario Provincial Standard Specification General Specifications for the Use of Explosives (Ontario Provincial Standard Specifications, 2014) and describes specific measures that would be implemented if blasting is required. • Development of a construction monitoring plan. This plan may be used to validate that best management practices are being implemented and that mitigation actions taken are effective. Where mitigation is not providing a reduction to overall impacts, mitigation options should be re-assessed.	• Residual change to air quality	• Context: Ecological, Social • Magnitude: Negligible • Direction: Negative • Geographic Extent: Local Study Area • Duration: Short-Term • Frequency: Infrequent • Reversibility: Reversable • Probability: Possible to Probable • Significance: Not Significant • Prediction Confidence: Moderate • Direct / Indirect: Direct

9.5.4.2 Greenhouse Gases

9.5.4.2.1 Project-Environment Interactions

As a component of the effects assessment, the Project activities were reviewed to find potential environmental interactions. These interactions were then assessed for potential effects (**Table 9.5-20**).

Table 9.5-20: Project-Environment Interactions - Greenhouse Gases

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction and Operation**	• All Project Activities	• Greenhouse Gases	• Quantification of Greenhouse Gas emissions (carbon dioxide, methane, nitrous oxide) expressed as carbon dioxide equivalent	• Change in Greenhouse Gas emissions expressed as tonnes of (carbon dioxide equivalent

9.5.4.2.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following greenhouse gases definitions apply to the effects assessment.

Ecological Context

For the greenhouse gas assessment, ecological context is directly related to changes in greenhouse gas emissions.

Magnitude

The magnitude of the Community Access Road's greenhouse gas contributions from Construction and Operations are assessed through comparison to the total provincial transportation emissions (in other words, road transportation sector). As per the most recent National Inventory Report (Environment and Climate Change Canada, 2025), a total of 40,907 kilotonnes of carbon dioxide equivalent was emitted from Ontario's road transportation sector, and a total of 156,994 kilotonnes of carbon dioxide equivalent was emitted from all Ontario sectors which exclude emissions from land use changes. **Table 9.5-21** provides definitions of greenhouse gases magnitude.

Table 9.5-21: Greenhouse Gases Magnitude Definition

Magnitude Level	Definition	Rationale
• **Negligible**	• Up to 0.1 percent of the Provincial Road Transportation Greenhouse Gas Totals • Under 41 kilotonnes of annual emissions thresholds (carbon dioxide equivalent)	• Releases of greenhouse gases and their accumulative in the atmosphere influence regional, national, and global climate and may affect emission reduction targets for greenhouse gases that have been set or are being developed federally and provincially. The magnitude has therefore been established as a percent contribution to provincial totals to assess the significance of Project emissions and hence potential effect on provincial reduction targets that may exist.
• **Low**	• 0.1 percent to 0.5 percent of Provincial Road Transportation Greenhouse Gas Totals • 41 to 205 kilotonnes of annual emissions thresholds (carbon dioxide equivalent)	• Same as previous
• **Medium**	• 0.5 percent to 1 percent of Provincial Road Transportation Greenhouse Gas Totals • 205 to 408 kilotonnes of annual emissions thresholds (carbon dioxide equivalent)	• Same as previous
• **High**	• >1 percent of Provincial Road Transportation Greenhouse Gas Totals • Above 409 kilotonnes (carbon dioxide equivalent)	• Same as previous

9.5.4.2.3 Residual Effects – Construction Phase

9.5.4.2.3.1 Potential Effects

The potential effects of the Project's construction on greenhouse gases include direct emissions from construction mobile equipment, blasting operations, and land use changes.

Annual emissions for each source category were estimated for a typical construction year (in other words, 40 kilometres of road built in a year). Construction mobile equipment, include nonroad construction machinery and on road construction vehicles (for example, road trucks), are estimated to generate approximately 18 kilotonnes of

carbon dioxide equivalent per year and 81 kilotonnes of carbon dioxide equivalent for the entire construction phase.

Quarry and road blasting are expected to generate approximately 0.4 kilotonnes of carbon dioxide equivalent per year and 1.8 kilotonnes of carbon dioxide equivalent of the entire construction phase.

During a typical construction year, the Project's annual Greenhous Gas emissions, without land use changes, are estimated to be approximately 19 kilotonnes of carbon dioxide equivalent.

9.5.4.2.3.2 Mitigation and Enhancement Measures

Best management practices that are typically employed during construction activity can be implemented to help reduce overall Project impacts on the surrounding environment during periods of construction.

The Ontario Ministry of Transportation identifies potential mitigation measures that may be taken, if feasible, for transportation-related projects in the Ontario Ministry of Transportation Environmental Guide for Assessing and Mitigation the Air Quality Impacts and Greenhouse Gas Emissions for Provincial Transportation projects (Ontario Ministry of Transportation, 2020).

It is recommended to develop a construction management plan after the final design and before construction begins. This plan should detail the selected mitigation measures with respect to greenhouse gas emissions, allowing for a more refined and efficient approach to controls, costing, and Project scheduling. The specifics of the mitigation measures and best management practices will be clearer during the detail design and construction submittal process.

Below is a list of examples of these practices and measures. It is suggested that mitigation measures incorporate Ontario Ministry of Transportation recommendations as well as construction industry best practices. Where feasible, the following mitigation measures are suggested to help reduce overall residual effects. Additional, a construction monitoring plan should be created during the final design and construction submittal periods to confirm best management practices are being followed.

- Implementing anti-idling policies or procedures to reduce total vehicle idling times
- Planning strategic haul plans to reduce the overall number of haul trips required for aggregate material demands by considering sourcing material from the closest available material transfer points
- Maintaining equipment as per manufacturer specifications

- Using fuel-efficient vehicles with low emissions
- Developing a construction monitoring plan that may be used to validate that best management practices are being implemented and that mitigation actions taken are effective. Where mitigation is not providing a reduction to overall impacts, mitigation options should be re-assessed.
- Where possible / feasible, considerations may be taken during route planning to avoid high-carbon stock areas such as dense forests. Although reforestation and afforestation of the land areas beyond the Right-of-Way are not planned, natural growth of vegetation (for example, grasses) are anticipated after the construction.
- Preserving and reusing the topsoil removed during construction helps to preserve the existing soil structure and thus reduces the loss of carbon in soils. Using advanced construction techniques and processes also reduces soil carbon loss. For instance, the Project will be using a “floating road” technique for road construction on wetlands which reduces the need for extensive soil excavation and disturbance.

9.5.4.2.3.3 Predicted Residual Effects

The Project’s annual construction emissions, are below 0.5 percent of Ontario’s road construction total greenhouse gas emissions. Greenhouse gas emissions from construction are considered to be of a negligible magnitude. During the assessment of annual greenhouse gas emissions, emission-generating activities were assumed to occur at a continuous frequency throughout construction and are considered to be irreversible. The likelihood of greenhouse gas residual effects was considered to be probably and the prediction confidence was ranks as low to moderate.

9.5.4.2.4 Residual Effects – Operations Phase

The direct greenhouse gas emissions during the Operation phase of the Project include emissions from the future road traffic and land use change (in other words, emissions resulting from carbon loss in organic soils distributed over a 20-year period).

The road traffic on the proposed Community Access Road is anticipated to generate approximately 27 kilotonnes of carbon dioxide equivalent per year and a total of 401 kilotonnes of carbon dioxide equivalent for the entire 30-year assessment period. A 20-year assessment period is recommended in the Ontario Ministry of Transportation Guideline for Assessing for Air Quality and Greenhouse Gases for Ontario Transportation Projects (Ministry of Transportation, 2020). The 20-year assessment period includes approximately 5 years of construction and 15 years of operation.

Greenhouse gas emission estimates for the future road traffic were conservatively based on the projected peak traffic volume on the proposed Community Access Road in the 2046 year (AECOM, 2024). The actual greenhouse gas emissions each year are expected to very depending on factors such as the actual traffic volume in the year. Improvements in vehicle emission controls and fuel efficiencies may also lead to variations in reported annual greenhouse gas emissions.

The Project's operation is expected to reduce greenhouse gas emissions from existing air travel and winter road travel. As per the Strategic Assessment of Climate Change Technical Guide, the reduced greenhouse gas emissions due to the shift of travel forms can be accounted as avoided domestic emissions in calculating the Project's net greenhouse gas emissions.

The Project's operation is expected to reduce approximately 0.02 kilotonnes of carbon dioxide equivalent per year and a total of 0.3 kilotonnes of carbon dioxide equivalent for the assessment period for Project operation. The low greenhouse gas emissions from the existing winter travel are attributed to low traffic volume and road accessibility.

Note that the existing greenhouse gas emissions from winter road travel were estimated based on the current traffic volume and are assumed to remain constant for the no-build scenario. Vehicular travel on the existing road is anticipated to be negligible once the Community Access Road becomes operational and therefore the greenhouse gas emissions will be zero from the operation year of the Project.

The Project is anticipated to partially displace existing air travel with road vehicle traffic and result in greenhouse gas reductions due to avoided air travel. However, the Project's effects on existing air travel are not quantitively assessed due to the limited information on existing flights and high uncertainties associated with estimates of avoided or increased air travel.

9.5.4.2.4.1 Mitigation and Enhancement Measures

The Project mitigation measures during operations to reduce greenhouse gas emissions are less in control of the Owner / Operator and more directly related to the road user and regional governing body. There are a number of federal and provincial actions in place or proposed to reduce vehicle greenhouse gas emissions. The following regulations are outlined in the Ministry of Transportation Air Quality and Greenhouse Gas Guide (Ministry of Transportation, 2020), all of which aim to reduce vehicle related greenhouse gas emissions:

- The federal Passenger Automobile and Light Truck Greenhouse Gas Emissions Regulations (SOR/2010-201)

- Regulations Amending the Passenger Automobile and Light Truck Greenhouse Gas Emissions Regulations (SOR/2014-207)
- Heavy-duty Vehicle and Engine Greenhouse Gas Emission Regulations (SOR/2013-24)
- Regulations Amending the Heavy-duty Vehicle and Engine Greenhouse Gas Emission Regulations and Other Regulations Made Under the Canadian *Environmental Protection Act*, 1999 (SOR/2018-98)

It is expected that as time progresses and more fuel-efficient vehicles are used on the road, annual greenhouse gas emissions on a per-vehicle basis will decrease over the lifespan of the Project during the Operation phase.

9.5.4.2.4.2 Predicted Residual Effects

The Project's annual Operation emissions are below 0.1 percent of Ontario's road transportation total greenhouse gas emissions and is considered to be negligible in magnitude. greenhouse gas emissions are expected to have a long-term effect and continuously emitted from vehicular traffic and is considered irreversible. The likelihood is considered probable and the prediction confidence is considered moderate.

9.5.4.2.5 Potential Effects – Land Use Changes

Land use changes due to Project construction result in carbon stock changes and subsequent direct greenhouse gas emissions. The Project's construction is expected to convert different land uses (for example, forest land) into settlements (in other words, roads and bridges) and thus impact the carbon stocks and carbon sequestration capabilities (in other words carbon sink) of land uses within the Construction Disturbance Area. The change of carbon stocks for land uses within the Project Disturbance Area is assessed as an emission to the atmosphere as carbon dioxide. In addition, half of the wood in forest land will be, stockpiled and burned, resulting in releases of greenhouse gas emissions.

The land use changes resulting from the road construction are expected to generate approximately 277 kilotonnes of carbon dioxide equivalent per construction year and 17 kilotonnes of carbon dioxide equivalent per construction year and 17 kilotonnes of carbon dioxide equivalent per operation year due to the delayed, gradual loss of carbon stock in soil and subsequent carbon dioxide emissions. During the 20-year project assessment period, the land use changes due to road construction resulted in total greenhouse gas emissions of 1,485 kilotonnes of carbon dioxide equivalent.

The estimated losses of carbon storage in biomass, dead organic matter, and social organic matter for the entire Project period at 171 kilotonnes, 13 kilotonnes, and 94 kilotonnes, respectively. Following the Strategic Assessment of Climate Change Technical Guide, the losses of carbon stocks in carbon pools are treated as carbon dioxide emissions to the atmosphere, which resulted in total greenhouse gas emissions from 1,485 kilotonnes from land use change.

During a typical construction year, a total loss of 75 kilotonnes of carbon stocks are estimated from all carbon pools in both forest land and wetlands.

The land use changes due to Project construction also have potential effects on carbon sinks. The exiting land uses within the Construction Disturbance Area mainly include forest land and wetlands. The carbon sink of forest land is assumed zero as the forest within the Construction Disturbance Area have either reached or surpassed the age for the maximum carrying capacity. Wetlands within the Construction Disturbance Area are dominated by peatland classes such as Fen (33.$) and Swamp (63.8 percent) which act as sources of carbon emissions rather than carbon sinks. Overall, the existing land uses within the Construction Disturbance Area are estimated to release 1,646 tonnes of carbon annually.

The Project construction will change the existing land uses into settlements (in other words, road and bridges) which are assumed to have zero carbon sinks after the construction. Following the method for estimating carbon sink impact in the Strategic Assessment of Climate Change technical guide (Equation 5), the estimated carbon sink impact for the Project is an estimated lost potential to release about 165 kilotonnes of carbon into the atmosphere. From the carbon sink analysis perspective, the Project has positive impacts on carbon sinks as the disturbed land acted as a source of carbon emissions. However, the land use changes due to the Project's construction will cause a loss of carbon storage in carbon pools and result in subsequent greenhouse gas emissions to the atmosphere.

9.5.4.2.5.1 Mitigation and Enhancement Measures

Carbon loss due to land use change (for example, converting forest into roads) and subsequent effects on greenhouse gas changes are inevitable. Mitigation measures can be taken to preserve existing carbon stocks as much as possible but can not fully eliminate the residual effect.

Where feasible, considerations may be taken during route planning to avoid high-carbon stock areas such as dense forests. Although reforestation and afforestation of the land areas beyond the Right-of-Way are not planned, natural growth of vegetation (for example, grasses) are anticipated after the construction.

Preserving the reusing the topsoil removed during construction helps to preserve the existing soil structure and thus reduce the loss of carbon in soils. Using advanced construction techniques and processes also reduces soil carbon loss. For instance, the Project will be using a “floating road” technique for road construction on wetlands which reduces the need for extensive soil excavation disturbance.

9.5.4.2.5.2 Predicted Residual Effects

The Project’s maximum annual greenhouse gas emissions from land use changes account for approximately 0.18 percent of Ontario’s total. The magnitude of greenhouse gas emissions from land use changes is considered low (in other words, from 0.1 percent to 0.5 percent of Ontario’s total). The duration of greenhouse gas residual effects from land use changes is considered long-term and the frequency is considered as continuous. Land use changes are deemed irreversible. The likelihood associated with land use change was assesses as probable and the prediction confidence is assessed as low.

9.5.4.2.6 Summary of Residual Effects

Table 9.5-22 provide a summary of the greenhouse gases residual effects. Detailed information is included in **Appendix S**.

Table 9.5-22: Summary of Residual Effects for Greenhouse Gases

Discipline / Valued Component	Predicted Residual Effect	Context	Direct / Indirect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Likelihood / Probability of Occurrence	Significance	Prediction Confidence
• Greenhouse Gases	• Greenhouse Gas Emissions - Construction	• Change in Greenhouse Gas Emissions	• Direct	• Negative	• Negligible	• Sectoral	• Long Term	• Continuous	• Irreversible	• Probable	• Not Significant	• Low to Moderate
• Greenhouse Gases	• Greenhouse Gas Emissions - Operations	• Change in Greenhouse Gas Emissions	• Direct	• Negative	• Negligible	• Sectoral	• Long Term	• Continuous	• Irreversible	• Probable	• Not Significant	• Moderate
• Greenhouse Gases	• Greenhouse Gas Emissions - Land Use Change	• Change in Greenhouse Gas Emissions	• Direct	• Negative	• Low	• Regional	• Long Term	• Continuous	• Irreversible	• Probable	• Not Significant	• Low

9.5.5 Cultural Heritage and Archaeology

9.5.5.1 Project-Environment Interactions

As a component of the effects assessment, the Project activities for cultural heritage and archaeology were reviewed to find potential environmental interactions.

Table 9.5-23: Project-Environment Interactions

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction and Operation**	• Clearing and grubbing • Grading and excavation • Drainage installation • Bridge or culvert construction • Pits and quarries • Access roads	• Cultural Heritage and Archaeology	• Presence and integrity of known and previously unidentified archaeological sites	• Construction and operation of the Community Access Road may result in ground disturbance that could damage or destroy culturally significant sites or known or previously unidentified archaeological resources.

9.5.5.2 Discipline-Specific Characteristics

Several factors are considered when evaluating potential effects on identified cultural heritage and archaeological resources. These are outlined in a document set out by the Ministry of Citizenship and Multiculturalism and include:

- Magnitude: the amount of physical alteration or destruction which can be expected;
- Severity: the irreversibility or reversibility of an effect;
- Duration: the length of time an adverse effect persists;
- Frequency: the number of times an effect can be expected;
- Range: the spatial distribution, widespread or site-specific, of an adverse effect; and
- Diversity: the number of different kinds of activities to affect a heritage resource.

9.5.5.3 Potential Effects

The following **Table 9.5-24** summarizes direct and indirect impacts to the potential Mid-Albany Cultural Heritage Landscape and its potential Cultural Heritage attributes within the Local Study Area along the Preferred Route. These potential heritage attributes include identified Indigenous Knowledge areas, data points, and routes, in addition to provincial parks and the overall landscape. To assist in this process, data points were numbered and mapped along the Preferred Route. Mapped data from other Indigenous communities, including data points, areas, trails, or other features, are considered in the analysis below, but are not identified in the supplementary mapping due to confidential nature of the information and by request of the Indigenous communities.

Table 9.5-24: Preliminary Cultural Heritage Impact Assessment of the Construction Disturbance Area of the Preferred Route

Potential Cultural Heritage Landscape	Summary of Potential Heritage Attributes	Discussion of Impacts	Proposed Mitigation and Next Steps
Mid-Albany Cultural Heritage Landscape	• 9 General Harvest Areas • 50 Specific Harvest Areas	• Direct impacts are anticipated. – The Construction Disturbance Area of the Preferred Route is anticipated to directly overlap all 9 General Harvest Areas in addition to 14 specifically plotted Harvest Areas – Construction-related activities and / or the long-term use of the road may result in displacement of traplines and the fragmentation and / or degradation of terrestrial habitat. This would negatively affect the distribution of furbearing animals, birds, and ungulates, thus affecting the viability of traplines and hunting areas. – Construction-related activities and / or the long-term use of the road may result in the blockage or channelization of watercourses, changes to banks or riverbeds, and increased sedimentation as a result of excavation and / or dust. This would negatively affect the quality, connectivity, and quantity of aquatic habitat and the viability of fishing areas. • Indirect impacts are anticipated – Construction-related activities and the long-term use of the road may impact aquatic and terrestrial habitat beyond the immediate Construction Disturbance Area of the Preferred Route. There is considerable potential for indirect impacts to habitat, within and beyond the Local Study Area that will negatively affect the availability of furbearing animals, ungulates, and birds and negatively affecting hunting, trapping, and fishing areas that are within the Local Study Area, but not directly overlapped by the Construction Disturbance Area of the Preferred Route. – The construction of the road will provide new access to the region that may indirectly adversely affect Harvest Areas through habitat changes and / or greater land use by non-local people.	• Mitigation: – Where possible, avoid direct impact to potential heritage attributes of the cultural heritage landscape during the design and implementation of the Project. Refinements of the Preferred Route during the design, and land-use within the 100 metres Construction Disturbance Area during construction should be planned to avoid impacting known Harvest Areas, Habitation Areas, Cultural, Spiritual, and Sacred Areas, Travel Routes, and Provincial Parks. If avoidance of potential heritage attributes is not feasible, then further assessment of the impacts and mitigation is required. • Next Steps: – A Cultural Heritage Evaluation Report should be completed by a Qualified Person(s) to determine the Cultural Heritage Value or Interest of the potential cultural heritage landscape. – If the Project continues to impact the area and it is determined that the potential cultural heritage landscape meets Ontario Regulation 9/06 or Ontario Regulation 10/06, then further assessment of impacts and mitigation is required by completing a Heritage Impact Assessment.
Mid-Albany Cultural Heritage Landscape	• 34 Habitation Areas	• Direct impacts are anticipated. – The Construction Disturbance Area of the Preferred Route is anticipated to directly overlap 5 Habitation Areas in addition to the Marten Falls First Nation Reserve. – Potential direct impacts may include the demolition or removal of campground areas and / or temporary or permanent changes in land access at or around Habitation Areas. • Indirect impacts are anticipated – Indirect impacts beyond the Construction Disturbance Area of the Preferred Route may include temporary or permanent changes in access to Habitation Areas, including either inhibiting access or opening access to non-local people.	• Same as above
Mid-Albany Cultural Heritage Landscape	• 15 Cultural, Spiritual, and Sacred Areas and associated context	• Direct impacts are anticipated. – The Construction Disturbance Area of the Preferred Route is anticipated to directly overlap 6 Cultural, Spiritual, and Sacred Areas. – Potential direct impacts may include the demolition or removal of cultural sites, and temporary or permanent changes in access to culturally significant areas, either impeding local access or opening greater access to non-local people. • Indirect impacts are anticipated – Indirect impacts beyond the Construction Disturbance Area of the Preferred Route may include temporary or permanent changes to the surrounding landscape that alter the context of culturally important areas.	• Same as above

Potential Cultural Heritage Landscape	Summary of Potential Heritage Attributes	Discussion of Impacts	Proposed Mitigation and Next Steps
Mid-Albany Cultural Heritage Landscape	• 29 Land Routes • 4 Water Routes	• Direct impacts are anticipated. – The Construction Disturbance Area of the Preferred Route is anticipated to intersect 27 Travel Routes including 23 land and 4 water routes. – Potential direct impacts to land routes may include the destruction of trail segments, the temporary or permanent obstruction of trails, and long-term changes in rights of way and / or trail access. – Potential direct impacts to water routes may include new transportation infrastructure such as bridges, culverts, and embankments that change the configuration of riverbanks and partially or fully obstruct waterway navigability and / or portage sites on a temporary or permanent basis. • Indirect impacts are anticipated – Indirect impacts to land routes may include changes in access to trails, either impeding local access or opening greater access to non-local people. – Indirect impacts to water routes may include temporary or permanent changes to prevailing currents, and / or long-term changes in patterns of debris deposition and sedimentation, thus altering the navigability of waterways.	• Same as above
Mid-Albany Cultural Heritage Landscape	• 2 Provincial Parks	• Direct impacts are anticipated. – The Construction Disturbance Area of the Preferred Route is anticipated to transect the Albany River Provincial Park. – The Albany River Provincial Park is noted for its varied topography, remoteness, and water routes. The Project may result in direct impacts including, but not limited to, changes to the local topography including the destruction, removal, or alteration of landforms and / or grades, and the addition of a bridge over the Albany River, affecting the scenic quality and / or the navigability of the waterway. • Indirect impacts are anticipated. – The Construction Disturbance Area of the Preferred Route is anticipated to pass within approximately 1 kilometre of the Ogoki River Provincial Park. – The Ogoki River Provincial Park is noted for its natural features, water routes, recreational opportunities, remoteness, and scenic qualities. Indirect impacts may include alterations to the landscape within and around the parks, thus altering the scenic context. – Additionally, the Project may result in temporary or permanent changes in access to both parks, opening both to greater use by non-local people.	• Same as above

9.5.5.4 Summary of Potential Effects

Table 9.5-25 provides a summary of the potential effects for archaeology, mitigation measures, and residual effects. Detailed information is included in **Appendix R**.

Table 9.5-25:Summary of Project Effects for Cultural Heritage and Archaeology

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect
• **Cultural Heritage**	• Construction	• There were 101 data points identified with cultural heritage relevance within the Local Study Area of the Community Access Road of which 30 are anticipated to be overlapped and directly impacted by the Community Access Road. These points include 99 in Marten Falls data points, one Neskantaga First Nation data point, and one Aroland First Nation data point composed of: – 52 identified harvest areas, including thirty-six animal harvest areas, thirteen fish harvest areas, and three plant harvest areas; – 10 cultural, spiritual, and sacred areas; – 30 habitation areas; and – 9 travel routes. • The Preliminary Impact Assessment further identified that of the 101 data points, 30 are anticipated to be directly impacted by the Community Access Road, including: – 14 identified harvest areas, including eight animal harvest areas and six fish harvest areas; – 2 cultural, spiritual, and sacred areas; – 5 habitation areas; and – 9 travel routes. • It should be noted that the Indigenous Knowledge data points used in this study could be connected to one another and to the wider landscape. Therefore, the identification of data points anticipated to be directly impacted does not preclude impacts to other points within or near the Local Study Area, nor may they be readily confined to the Project footprint. • While direct or indirect impacts to data points may be assessed according to standard provincial criteria, those potential impacts are better understood as impacts to a cultural heritage landscape, rather than to individual data points.	• To address the probable slippage between direct and indirect impacts, potential impacts are best understood as impacts to cultural heritage landscapes, rather than to individual data points. It is recommended that any future reporting be organized as assessments of two cultural heritage landscapes; the Ogoki River and the Albany River. The reports should be thematically organized to include the cultural heritage themes associated with those rivers (harvest areas, habitation areas, cultural, spiritual, and sacred areas, and travel routes). Moreso than individual data points, assessing the Albany and Ogoki rivers for cultural heritage value or interest will provide the most accurate assessment of cultural heritage value and impacts of the Community Access Road. • For the cultural heritage landscapes and associated data points within the Local Study Area general mitigations measures should be developed and observed, including the following: – Continue to refine the Local Study Area to avoid direct adverse impacts to identified cultural heritage landscapes and associated data points, where possible. – Construction activities should be suitably planned and undertaken to avoid impacts, including but not limited to: – Informing construction crews of the location of known cultural heritage landscapes and associated data points. – Confining construction-related activities to the proposed right-of-way of the Community Access Road. – Establish a construction monitoring process which includes procedures and no-go zones and procedures to avoid impacts to the cultural heritage landscapes and associated data points. • Should there be changes to the Community Access Road, a qualified person(s) should assess whether they will affect the assessment of existing heritage conditions and preliminary impacts and provide advice on any required revisions to the recommendations in the Cultural Heritage Report (Appendix Q). • Cultural Heritage Evaluation Report on the Ogoki River. • Cultural Heritage Evaluation Report on the Albany River.	• -
• **Cultural Heritage**	• Operations	• At this time there are no identified potential effects for the operational or maintenance phase.	• At this time there are no identified potential effects for the operational or maintenance phase.	• -

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect
• **Archaeology**	• Construction	• As described in **Section 8.3.6.6**, two Stage 1 and one partial Stage 2 Archaeological Assessment were completed in the Local Study Area. The results of these studies found that additional archaeological work is required to identify potential effects, and future mitigations.	• To mitigate potential effect to archaeological resources the following mitigations are required: • Should an avoidance and protection strategy for the Caviar (EiIp-1) site be implemented during construction, it must include: – Placement of a temporary barrier around the site, including a 20-metre protective buffer of land surrounding the site; – Monitoring by a licensed consultant archaeologist for any construction activities that occur within 70 metres of the site; – The issuance of “no-go” instructions within the 20-metre buffer to all onsite construction personnel or others involved in the construction process (in other words, engineers, architects). Refer to Section 4.1.1 of the Standards and Guidelines for Consultant Archaeologists (Ontario Government of Ontario, 2011); – Illustration of the location of the area to be avoided on contract drawings, including explicit instructions to avoid the area; – The presence of a licensed archaeologist on site to inspect fence installation, inspection of the site by a licensed archaeologist after the completion of all soil-disturbing activities, and reporting of the effectiveness of the avoidance and protection strategy to the Ministry of Citizenship and Multiculturalism; and, – Should future repairs or improvements be required near the Caviar (EiIp-1) site or should changes to the Project area be required, archaeological monitoring by a licensed archaeologist will be required to help maintain that the No-Go zone remains in place and that the archaeological site is protected from construction or soil disturbance activities. • If impacts will be proposed to Caviar (EiIp-1), a Stage 3 AA is required. The Stage 3 AA for Caviar (EiIp-1) must include the hand excavation test unit methodology as outlined in Section 3.2 and Table 3.1 of the Standards and Guidelines for Consultant Archaeologists (Government of Ontario, 2011), to further test the nature and density of the site. Given that Caviar (EiIp-1) is primarily located on exposed bedrock, hand excavation covering the entire site may not be possible. Therefore, the Stage 3 AA would consist of site documentation and recording.	• A Cultural Heritage Evaluation Report will be completed prior to detail design. As per the approved Cultural Heritage Study Plan, a cultural heritage and archaeology effects assessment will be completed when detail design is complete.
• **Archaeology**	• Operations	• At this time there are no identified potential effects for the operational or maintenance phase.	• Not Applicable	• Not Applicable

9.5.6 Community Well-Being

9.5.6.1 Project-Environment Interactions

An analysis of Project-environment interactions for community well-being that are likely to have a potential effect is provided in **Table 9.5-26**.

Table 9.5-26: Project-Environment Interactions – Community Well-Being

Project Phases	Project Activities To Have Potential Effect on Community Well-being
• **Construction**	• Mobilization of Equipment and Supplies • Temporary Construction Staging Areas • Temporary Access Roads and Trails • Temporary Construction Camps • ROW Clearing and Grubbing • Brush and Timber Disposal • Pits and Quarries • Temporary Concrete Batch Plants / Trails and Staging Areas • Drilling / Blasting / Aggregate Production • Road Construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and Culvert Installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction Site Restoration • Pits and Quarries
• **Operations**	• Road Usage • Road Maintenance

9.5.6.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following Community Well-Being community well-being definitions apply to the effects assessment.

Ecological and Social Context

The ecological context of effects has been considered in developing the effects criteria, such as species sensitivity and resilience, and includes Indigenous Knowledge (where available). The ecological context of the effect includes a discussion of the environmental consequences of the predicted effect. The effects assessment also considers timing, such as when the effect could occur during a species lifecycle window, or culturally significant period of time. The social context of the effect includes a discussion of the social and cultural consequences of the predicted effect. The current and future sensitivity and resilience of the valued component to changes caused by the project has also been considered.

Table 9.5-27: Community Well-being Discipline-Specific Magnitude Definitions

Valued Component	Negligible	Low Magnitude	Moderate Magnitude	High Magnitude
• **Sustainable Population Growth**	• No measurable change in population trends	• Minor population fluctuations, absorbed by existing infrastructure	• Some in-migration or out-migration requiring housing or service adjustments	• Population changes straining infrastructure, housing, and services
• **Labour Market Dynamics**	• No measurable effect on employment or job market	• Small, temporary changes in job opportunities	• Noticeable shifts in job availability, requiring training or new policies	• Permanent work force restructuring, creating dependence on external labour or job displacement
• **Economy**	• No measurable impact on local businesses, community budgets, revenues or regional economy.	• Minor new opportunities or challenges, minor shifts in expenditures or revenues, easily absorbed; minor regional economic fluctuations.	• Business growth or decline requiring investment, adaptation, or policy changes; noticeable budgetary impacts requiring reallocation of funds or new revenue sources; moderate regional growth (or decline) requiring policy intervention.	• Permanent economic restructuring, leading to dominance of external businesses or loss of local enterprises; large-scale financial burden or revenue loss; permanent economic shifts increasing disparities between communities.
• **Community Access to Infrastructure and Services**	• No measurable change in access or service levels	• Slight measurable change in access or service levels, absorbed by existing infrastructure	• Measurable change in access or service levels, requiring slight infrastructure adjustments	• Measurable change prompting consideration of infrastructure expansion
• **Housing**	• No measurable change in housing adequacy and suitability	• Minor repairs or upgrades become more feasible (for example, more frequent maintenance, better insulation).	• Some improvements in housing adequacy and suitability, but issues like overcrowding may persist in certain areas.	• Improved match between housing supply and community needs, addressing long-standing shortages.
• **Cultural Preservation and Change**	• No measurable change in cultural practices, identity, or language use	• Some opportunities for increased participation in cultural activities, traditional economy, or language use	• Noticeable increase in access to cultural activities, traditional economy, and language use, leading to stronger community connections	• Greater access and participation in cultural traditions, land-based practices, and language use, supporting long-term continuity
• **Community and Public Health**	• No measurable decline in community mental health outcomes or change in substance abuse.	• Minor decrease in negative mental health and minor increase in substance abuse, despite improved access to healthcare and treatment	• Moderate decrease in mental health and moderate increase in substance abuse, despite improved access to healthcare and treatment.	• Widespread decrease in mental health and increase in substance abuse, leading to noticeable decline in overall health outcomes for individuals and community well-being over time despite improved access to healthcare and treatment.
• **Access to Clean Water**	• No measurable impact on water quality or availability	• Minor improvements or disruptions in water availability or quality, with limited impact on costs or access	• Reduced transportation costs for bottled water and increased access to water testing and repairs to the water treatment plant, resulting in more reliable access to clean water	• Consistent and affordable supply of clean water, driven by improved water infrastructure, including long-term reductions in bottled water costs and improved water testing and treatment plant repairs, supporting sustainable access to clean water
• **Traditional Foods**	• No measurable impact on access, availability, access to store-bought foods, or quality of traditional foods.	• Improved access to traditional foods, but no significant change in availability or quality of traditional foods. • No change in reliance on store-bought foods.	• Improved access to traditional foods, observed decline in availability and / or quality of traditional foods.	• Improved access to traditional foods, significant and measurable decline in availability and / or quality of traditional foods. • Improved access (including reduced costs) associated with store-bought foods.
• **Public Safety**	• No measurable impact on crime rates, emergency response, or safety concerns	• Minor and short-term safety concerns	• Increased safety risks requiring some mitigation measures	• Significant and ongoing safety concerns requiring major interventions
• **Biophysical Factors Influencing Human Health**	• No measurable effect on air quality, noise and vibration, soil, or water	• Minor, temporary degradation in air quality, noise and vibration, soil, or water	• Noticeable degradation in air quality, noise and vibration, soil, or water requiring mitigation	• Significant, long-term degradation of environmental quality affecting health (for example, respiratory conditions)

9.5.6.3 Residual Effects – Construction Phase

9.5.6.3.1 Sustainable Population Growth

9.5.6.3.1.1 Potential Effects

Age Distribution

During construction, employment opportunities may lead to an increase in the working-age population in Marten Falls First Nation and Aroland First Nation, including both members and non-members moving into the community. This demographic shift could have some effects, such as changes in family structures, community dynamics, and social cohesion, particularly if many of the returning or new residents are young men. Social integration (family reunification) challenges may arise for these individuals, especially if they have spent a long time away from the community.

Gender Distribution

Construction employment opportunities, which have historically been male dominated, may lead to a temporary rise in the male population, resulting in an effect of gender imbalance within the communities. The potential changes in employment dynamics requires Gender-Based Analysis Plus considerations, particularly for women and gender-diverse individuals, who may bear caregiving responsibilities if more male family members are hired for the project.

Community Population

There is potential for an increase in the percentage of community members from Marten Falls First Nation living on-reserve versus off-reserve. As community members living off-reserve gain construction-related employment, it is possible that they may bring their spouse and children to live in the community so they can maintain close relationships with family on days off from work. This rapid population increase could have a effect on community members as it may reduce community cohesion during construction.

9.5.6.3.1.2 Mitigation and Enhancement Measures

Age Distribution, Gender Distribution, Community Population

To mitigate effects to sustainable population growth during construction, the following measures will be implemented:

- The owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including topics

related to rapid population changes, social cohesion or (re)integration challenges.

- All construction workers (including on- and off-reserve members) will be housed in autonomous work camps to limit in-community demographic shifts and limit disruptions to social structures and community dynamics.
- Owner / operator to implement Diversity, Equity, and Inclusion hiring policy. This could be enhanced through training programs, job fairs, child-case supports, and outreach, to actively prioritize women in construction-related employment opportunities and reduce gender disparities in the work force and therefore reduce gender imbalances within the community.

9.5.6.3.1.3 Predicted Residual Effects

With mitigation measures effectively implemented, there are no residual effects related to sustainable population growth during construction.

9.5.6.3.2 Labour Market Dynamics

9.5.6.3.2.1 Potential Effects

Labour Force

The construction spending for the project is expected to total $1.3 billion. There are barriers to employment which may prevent the hiring of local community members. Most of the jobs created during construction are expected to be supplied from outside the local communities, due to limited local labour force capacity and available regional labour force capacity. As a result, there may be a shortfall in available labour in comparison to the demand for jobs during construction.

Around 3,490 direct jobs from the project are expected to occur in Ontario during construction, accompanied by 3,240 indirect jobs and about 1,870 induced jobs. With a total employment effect of approximately 8,600 jobs in Ontario, construction could lead to about 930 jobs in the rest of Canada. This totals about 9,530 jobs in Canada overall during construction.

Earnings

These employment effects are expected to directly create about $360 million in Ontario's labour income, along with an indirect effect of $252 million and an induced effect of $109 million. This implies an average labour income of around $84,000 per job. For Canada overall, the total labour income effect is $789 million, which gives an average labour income of about $82,800 per job. Considering the effects on Ontario's Gross Domestic Product (which measures the income produced, rather than income

received), the expected total effect in Ontario is around $1.2 billion. This implies an average income produced of nearly $137,100 per job. The gap between this ratio and the labour income to employment ratio is largely due to net profits and net taxes. On the other hand, the expected total effect on Canada's Gross Domestic Product is over $1.3 billion, which implies an average income produced of $138,300 per job. The ratio of Gross Domestic Product to employment is also sometimes used as a rough measure of productivity (amount produced relative to amount used).

There is potential for an increase in employment among men in both Marten Falls First Nation and Aroland First Nation, as they make up a slightly larger proportion of those participating in the labour force and may be more familiar with work environments related to construction or land based activities. In Aroland First Nation, men are represented in agriculture, manufacturing, and public administration, sectors that may offer some transferable skills to construction. In Marten Falls First Nation, men participate primarily in educational services and public administration, which offer fewer direct pathways into construction roles. Women in Marten Falls First Nation, who are represented in educational services, health care and social assistance, accommodation and food services, and public administration, may face additional challenges entering construction because these sectors are not closely aligned with typical construction occupations. In Aroland First Nation, women participate mainly in construction and educational services, with limited involvement in other sectors. As a result, any increase in employment during construction is expected to be experienced unevenly between men and women across both communities.

Indirect input-output economic effects occur within the supply chain as a result of industry linkages. When demand for a specific product or service increases, the industries supplying the necessary materials, labour, or support services also experience growth.

9.5.6.3.2.2 Mitigation and Enhancement Measures

To better meet the increase in demand for local labour, the following mitigation measures are recommended:

- Project owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road. The working group could explore support for unemployed community members by identifying employment barriers and offering job readiness programs to support community members facing unemployment.

- Owner / operator will implement Community Readiness Strategies and Adaptive Management Plans to assess and respond to community needs through construction.
- Owner / operator will provide information on available opportunities to help Marten Falls First Nation and Aroland First Nation community members understand the opportunities and provide time to obtain the necessary qualifications.
- Owner / operator will create a Local Training Plan to complete a local skills assessment and utilize local labour force.
- Project owner will provide ongoing job readiness programs, continuously enhancing training opportunities to support community members in their transition into the workforce and long-term career growth. Timing of training and education will be coordinated in advance of hiring to reduce barriers to participation.
- Owner / operator will implement Diversity, Equity, and Inclusion hiring policy. This could be enhanced through training programs, job fairs, and outreach, to actively prioritize women in construction-related employment opportunities and reduce gender disparities in the work force.
- Owner / operator will implement a gradual work force integration for community members, introducing shorter workdays and shift rotations (for example, starting with 2-3 days on with a day or two break instead of 10 consecutive days) to ease new workers into construction roles.

Enhancement measures focused on improving employment outcomes include:

- Collaboration between the project owner and organizations to provide training programs to prepare local labourers for project-related jobs in construction and transportation. Early investment in skills development will help confirm work force readiness when jobs become available several years in the future.
- Owner / operator should prioritize hiring Marten Falls First Nation and Aroland First Nation members, as well as other Indigenous community members.
- During detail design, the project owner should explore funding opportunities through sources such as the Province of Ontario and Indigenous Services Canada.
- The project owner should work with Kiikenomaga Kikenjigewen Employment and Training Services and other Indigenous training organizations to provide

culturally appropriate education, training, and employment opportunities for community members.

- The owner / operator should collaborate with the Province of Ontario and training institutions to support work force development through apprenticeships and on-the-job training. This could be integrated into social procurement requirements, so that hiring prioritizes local and Indigenous workers while addressing barriers to participation.

9.5.6.3.2.3 Predicted Residual Effects

There are no adverse residual effects for the labour market dynamics during construction of the Project, provided mitigation measures to promote local hiring and remove employment barriers are implemented.

There are potential **positive** residual effects on the economy and the labour market through wider economic benefits. Long-term economic growth requires either higher inputs (more labour and capital), or higher productivity (more productive labour and capital). The Project is expected to have a direct, positive effect on the productivity of individuals and businesses in the region, which can result in improved opportunities and higher earnings. This occurs through two effects:

- Improved access to inputs: Project can lead to increased connectivity that increases the accessibility to a variety of inputs for businesses in the region. This increased access to inputs improves the productivity of these businesses.
- Increased agglomeration: Project can lead to improvements in productivity of businesses through cost savings, knowledge spillovers, efficiency improvements, and facilitation of in-person meetings.

Another potential **positive** and beneficial residual effect is land value uplift. The Project's investment in the Community Access Road is expected to have a positive effect on the value of land that is surrounding the transportation infrastructure. Increased connectivity, greater access, improved travel times, higher safety benefits, and enhanced economic potential are some of the factors that positively affect the value of the land. This increase in land value can increase the wealth of the population and offer more opportunities for efficiency improvements in the labour market. The increase in land value can provide additional resources that allow people to be matched to their desired jobs in a more efficient manner.

Furthermore, increase in the value of land that is held collectively by a First Nation may generate additional revenue and benefits for the community. This increase in land value allows for the shared benefits to be distributed among community members in a way that reflects the community's values. This differs from an increase in value of land that is

owned outright (freehold), where owners may extract benefits in a non-communal manner.

Additionally, with the increase in labour market opportunities, there is a **positive** effect on diversifying the economy, which boosts the health of the economy and the labour market. With greater connectivity comes great opportunity for diversification. For instance, as the number of vehicles increases, there will likely be a need for additional resources to maintain vehicles, leading to employment opportunities as a mechanic, doing safety inspections and regular vehicle maintenance.

Overall, the Project, opportunities exist for Marten Falls First Nation, Aroland First Nation, and neighbouring First Nations to develop service businesses due to the Community Access Road and the related economic growth.

9.5.6.3.3 Economy

9.5.6.3.3.1 Potential Effects

Local Businesses and Commercial Activities

Marten Falls First Nation, as the only community directly connected to the road from the Project, is expected to benefit from new business opportunities that extend beyond the economic benefits associated with the road's construction and operation.

The Project is expected to create business opportunities for Indigenous companies, particularly in road construction and related transportation and service sectors during construction. Overall, these developments are anticipated to have a **positive** effect the business environment for Marten Falls First Nation and neighbouring Aroland First Nation.

During construction, there are potential concerns with respect to work zone effects. Construction of the Community Access Road may result in disruptions to certain individuals and businesses that are in the area close to where the road is being developed. There is therefore a potential **negative** effect of economic activity and construction interfering with local businesses or employers. This is arising from the direct effects of construction, as well as indirect effects through supply chain relationships.

Indirect input-output effects occur in the supply chain due to industry linkages. When demand for a specific product or service increases, the industries supplying the necessary materials, labour, or support services also experience growth. If there is higher direct demand for some product in the economy, then the businesses in the industries supplying that product are indirectly affected.

Public Finances

The Statistics Canada input-output tables provide multipliers for capturing the effects on taxes on products and taxes on production. Taxes on products are taxes payable per unit of a good or service sold, such as sales taxes. Taxes on production are taxes paid by enterprises and are related to operations, such as property taxes and payroll taxes. For taxes on income, the most recent Statistics Canada public finance data can be used to derive the personal income tax proportion of labour income, as well as the corporate income tax proportion of gross operating surplus. The three derived types of taxes on products, production, and income can then be broken down by level of government (federal, provincial, local, and Indigenous), based on the most recent Statistics Canada public finance data.

Note that the public finances measures rely largely on proxy indicators. Overview of community finances provides insight to level of government transfers and funds. For example, if there is a First Nation Development corporation, it may not show up on the band ledger. Furthermore, the tax structure is not the same on a reserve as on other regions. Businesses on Indigenous reserves have specific tax rules. Generally, First Nation-owned businesses operating on reserves are exempt from certain taxes under Section 87 of the Indian Act. This exemption applies to business income earned on a reserve and to goods bought on or delivered to a reserve.

Indirect effects on public finances occur in the supply chain due to industry linkages. When demand for a specific product or service increases, the industries supplying the necessary materials, labour, or support services also experience growth. If there is higher direct demand for some product in the economy, then the industries supplying that product are indirectly affected, which then leads to additional tax revenues.

Other general indirect effects could arise from people moving back to the community given the increase in economic activity and jobs. This increase in population and income would lead to higher demand, including the demand for housing.

Regional Economy

Summary of the regional economic effects of the $1.3 billion construction spending is shown in **Table 9.5-28** and **Table 9.5-29**, followed by sections for each economic indicator.

Table 9.5-28: Ontario Construction Effects

Ontario Construction Effects (millions $)	Direct Effects	Indirect Effects	Induced Effects	Total Effects
Output	1,300	852	400	2,552
Gross Domestic Product	485	424	270	1,179
Labour Income	360	252	109	723
Gross Operating Surplus	134	168	113	415
Taxes on Products	4	7	38	48
Taxes on Production	7	12	21	39
Taxes on Income	93	78	41	212
Employment (jobs)	3,488	3,240	1,873	8,601

Source: Statistics Canada, 2026d, 2026e, 2026f; AECOM Analysis.

Table 9.5-29: Canada Construction Effects

Canada Construction Effects (millions $)	Direct Effects	Indirect Effects	Induced Effects	Total Effects
Output	1,300	1,031	495	2,826
Gross Domestic Product	485	512	322	1,318
Labour Income	360	295	134	789
Gross Operating Surplus	134	211	137	481
Taxes on Products	4	8	42	53
Taxes on Production	7	14	23	44
Taxes on Income	93	94	50	236
Employment (jobs)	3,488	3,775	2,269	9,532

Source: Statistics Canada, 2026d, 2026e, 2026f; AECOM Analysis.

Output

The $1.3 billion construction spending is expected to lead to total economic activity (output) in Ontario of $2.6 billion. For Canada, the total effects on output are estimated to be over $2.8 billion

Gross Domestic Product

Ontario's total economic value, measured by its Gross Domestic Product (income produced), is projected to be around $1.2 billion. Meanwhile, the total effects on Canada's Gross Domestic Product are expected to be over $1.3 billion.

Labour Income

Total effects on labour income are expected to be $723 million in Ontario, with half of those coming from the direct effects. The total effects on Canada's labour income are estimated to be $789 million.

Gross Operating Surplus

Ontario's gross operating surplus total effect is estimated to be $415 million, with the indirect effects being the most dominant. That is even more pronounced for Canada, with the estimated total effects being $481 million.

Taxes

The total effects on taxes in Ontario ($299 million) are led by taxes on income ($212 million), followed by taxes on products ($48 million) and taxes on production ($39 million). The total effects on taxes in Canada are estimated to be $333 million. This is led by taxes on income ($236 million), followed by taxes on products ($53 million) and taxes on production ($44 million).

Employment

The construction phase is expected to involve about 8,600 total jobs in Ontario, which includes around 3,490 direct jobs. The overall employment effect for Canada is expected to be 9,530 jobs, with the indirect effects on employment being most prominent, which highlights the labour-intensive linkages of the supply chain industries.

Indirect input-output effects occur in the supply chain due to industry linkages. If there is higher direct demand for some product in the economy, then the industries supplying that product are indirectly affected. In the context of the Project, the construction spending for the new Community Access Road directly affects the transportation engineering construction industry. The transportation engineering construction industry makes the first round of indirect expenditures on its supply chain industries. Those industries will then make their expenditures on their supply chain industries. The sum of all those indirect effects gives the total indirect effects, as discussed earlier, which represents a **positive** effect on the economy.

Prices

Based on the experience of other comparable communities, as discussed in **Section 5.2.4**, the new Community Access Road is expected to have **positive** effects on the overall quality of life, driven primarily by a reduction in prices and the cost of living, with better access to health care, social services, and family. There are no

significant anticipated effects on Gender-Based Analysis Plus sub-groups related to the overall change in the prices of goods. There may be some potential beneficial effects for those who spend more on products that experience price decreases, such as women who spend more on personal health items.

9.5.6.3.3.2 Mitigation and Enhancement Measures

Local Businesses and Commercial Activities

Mitigation measures to address potential business environment issues include:

- Owner / operator will implement Community Readiness Strategies and Adaptive Management Plans to assess and respond to community needs through construction.
- Owner / operator will create a Local Content Plan to utilize a certain dollar value or share towards local businesses and contractors.
- Owner / operator will consult with local businesses that would be potentially affected by work zone effects and determine the optimal times and conditions for the construction to take place, such as during off-peak times.

Enhancement measures focused on improving the business environment include:

- Owner / operator should prioritize hiring Marten Falls First Nation and Aroland First Nation members, as well as other Indigenous community members.
- During detail design, the project owner should explore funding opportunities through sources such as the Province of Ontario and Indigenous Services Canada.

Regional Economy

The mitigation measure to address potential regional economy issues includes:

- Owner / operator will consult with local businesses that would be potentially affected by work zone effects and determine the optimal times and conditions for the construction to take place, such as during off-peak times.

Enhancement measures focused on improving the regional economy include:

- Owner / operator should prioritize hiring Marten Falls First Nation and Aroland First Nation members, as well as other Indigenous community members.

- During detail design, the project owner should explore funding opportunities through sources such as the Province of Ontario and Indigenous Services Canada.

9.5.6.3.3.3 Predicted Residual Effects

Local Businesses and Commercial Activities

There are no adverse residual effects for the business environment during construction of the Project. Potential **positive** residual effects on the business environment through wider economic benefits. The Project is expected to have a **positive** effect on the productivity of individuals and businesses in the region. This can lead to improved economic opportunities and better long-run prospects for the community.

The Project's investment in the Community Access Road is expected to have a **positive** effect on the value of land that is surrounding the transportation infrastructure. This increase in land value can provide an additional benefit to the population and the local businesses. Transportation infrastructure generally improves land value. Reserve lands are sometimes leased out by First Nations; any increase in land value in proximity to a reserve may drive up land lease income Diversifying the economy can have a positive effect by creating more opportunities, strengthening economic stability, and improving the overall business environment.

Overall, given the unprecedented nature of the Project, it is a great opportunity for Marten Falls First Nation, Aroland First Nation, and neighbouring First Nations to develop service businesses due to the Community Access Road and the related economic growth.

Public Finances

There are no adverse residual effects for the public finances during construction of the Project. The **positive** effect is that the Project will generate government revenue.

Regional Economy

There are no adverse residual effects for the regional economy during construction of the Project.

9.5.6.3.4 Community Access to Infrastructure and Services

9.5.6.3.4.1 Potential Effects

Methods of Transportation in and Out of the Community

Construction is expected to increase reliance on winter roads and air transportation for the mobilization of equipment, supplies, and work force transportation to Marten Falls First Nation. The project is expected to increase road traffic related to the transport of employees, equipment, and supplies, particularly between key staging areas and construction sites. There may be negative effects of reduced safety along winter road transportation in and out of community, when heavy equipment or large shipments of materials may be brought into community. This increased use of the winter roads will be short-term, during construction, until the new Community Access Road is operational.

The airports in Marten Falls and Aroland First Nations will experience negative effects of increased use as a transit hub for equipment and material delivery as well as employees, and their families, traveling to and from the work sites. This increase in use of existing airports may result in potentially negative effects of scheduling challenges for community members.

Essential Infrastructure and Services

The construction of the Community Access Road to Marten Falls First Nation may have a negative effect due to additional strain on the already limited infrastructure and services in Marten Falls First Nation and Aroland First Nation. Both communities face major challenges related to water, wastewater, energy, and waste management systems, which may be worsened by the demands of road construction.

The Marten Falls First Nation water treatment plant has failed inspections over the past six years and remains under a boil-water advisory. Increased construction activity and a temporary influx of workers and community members returning home for employment, will heighten demand for potable water and wastewater treatment, placing further stress on an already overburdened system. The increased wastewater generation could exceed treatment capacity, heightening the risk of untreated sewage discharge into the environment, which could pose additional public health risks and threaten local water sources.

Construction activities will generate large amounts of waste, including residential and construction-related materials. Without adequate waste management systems, improper disposal could lead to soil and water contamination, negatively affecting local ecosystems and community health.

Both Marten Falls First Nation and Aroland First Nation rely on diesel-powered generators for electricity. Construction may increase energy demand, potentially straining power infrastructure. Without supplemental power sources, the community could experience disruptions in essential power-driven services, such as brown outs, where the voltage drops below the standard level, leading to weakened power supply, dimming lights, and potentially affecting sensitive equipment. Grey-outs, caused by large voltage drops, could result in noticeable dimming of lights, malfunctioning of electrical devices, or disruptions in essential services such as heating, lighting, and refrigeration. Such disruptions could compromise the community well-being of residents.

Construction will require a substantial supply of fuel for vehicles and machinery used throughout construction. This includes fuel for construction vehicles, equipment, and transportation vehicles for workers and materials. Increased fuel consumption could lead to supply shortages and increased costs in both Marten Falls First Nation and Aroland First Nation communities.

9.5.6.3.4.2 Mitigation and Enhancement Measures

Mitigation measures for community access to infrastructure and services during construction for Aroland First Nation include:

Methods of Transportation in and Out of the Community

Owner / operator will develop an Equipment Mobilization Plan with both Marten Falls First Nation and Aroland First Nation for the movement of equipment, personnel, supplies, and resources. Where possible, construction traffic should be separated from community traffic to improve safety and minimize disruptions. The mobilization plan should also include a clear communications strategy to keep the community informed of the mobilization schedule, making residents aware of periods of increased heavy equipment traffic on the winter road.

Owner / operator, when possible, will transport employees on a charter flight, to minimize disruption to existing passenger flight schedules servicing community needs.

Essential Infrastructure and Services

Mitigation measures for infrastructure and essential services during construction include:

All construction workers (including on- and off-reserve members) will be housed in autonomous work camps equipped with independent water, wastewater, and power systems. These systems need to be properly maintained to reduce reliance on community infrastructure and to prevent contamination risks.

The owner / operator will develop waste management policies to minimize waste production and support responsible disposal. Collaboration with the community will be prioritized to develop effective construction waste management and disposal strategies, incorporating local input.

The owner / operator will establish a secure fuel storage facility and confirm a reliable fuel supply throughout the construction season. Fuel deliveries will be planned in advance and transported via the winter road, reducing reliance on costly air transport and preserving community fuel resources. All fuel storage sites will comply with safety and environmental regulations to prevent spills and contamination.

The owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including topics associated with increasing pressure on local, essential services and infrastructure.

9.5.6.3.4.3 Predicted Residual Effects

Methods of Transportation in and Out of the Community

The anticipated effects are **negative** in direction, of **moderate** magnitude, and are limited in duration to the **short-term**. During construction, there may be a temporary increase in reliance on winter roads and air transport, despite coordination efforts. **Infrequent** but higher-than-usual traffic volumes on winter roads are **possible**, with **low** uncertainty, and could lead to accelerated deterioration, potentially shortening operational periods or increasing maintenance needs **locally**. Effect is **reversible**, as once the project mobilization is completed, transportation demands should return to pre-construction levels. Long-term following the completion of construction of the road, the winter road will be decommissioned.

Essential Infrastructure and Services

No adverse residual effects are anticipated.

9.5.6.3.5 Housing

9.5.6.3.5.1 Potential Effects

Housing Suitability

During construction, increased economic activity and job opportunities may lead to changes in household occupancy and housing demand within Marten Falls First Nation and Aroland First Nation. There is potential for a negative effect to housing suitability due to increased overcrowding as currently off-reserve community members return for

construction-related employment to live with on-reserve family. This may further increase if families of workers also return, resulting in higher household occupancy and potential overcrowding. Spousal or family relocations during workers' time off could directly contribute to increased demand for suitable housing within the community.

As more families temporarily move to Marten Falls First Nation or Aroland First Nation, demand for housing will rise. This could intensify existing housing shortages, potentially leading to overcrowding and putting additional strain on local infrastructure and services. The increased housing demand could particularly affect lower-income families and women-led households, who may face greater challenges in accessing suitable housing options. Overcrowding could disproportionately affect women and children, who are more likely to spend time at home, reducing privacy, safety, means for study, and overall well-being. Without adequate planning, these pressures could result in longer wait times for housing placements or insufficient living space for larger families, negatively affecting residents' quality of life in both Marten Falls First Nation and Aroland First Nation.

9.5.6.3.5.2 Mitigation and Enhancement Measures

Mitigation measures for effects on housing during construction include:

- All construction workers, including on- and off-reserve members, will be housed in autonomous work camps. This will help limit demographic shifts, reduce disruptions, and reduce additional pressure on community housing.
- The owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, which could include considering if converting construction camps to permanent housing is feasible through working group discussions with Marten Falls First Nation and Aroland First Nation. With advanced planning, construction camps could be built to higher quality standards, making them suitable for long-term residential use and helping to address housing shortages in the community.

9.5.6.3.5.3 Predicted Residual Effects

Housing Suitability

With the planned mitigation measures, no adverse residual effects on housing availability during construction are expected.

Accessibility of Building Homes and Shipping Materials

No effects on housing availability during construction are anticipated.

9.5.6.3.6 Cultural Preservation and Change

9.5.6.3.6.1 Potential Effects

Traditional Economy

The construction of the Community Access Road has the potential to have a effect on the traditional economy of Marten Falls First Nation and Aroland First Nation as land clearing for the road corridor, work camps, and pits and quarries, could lead to the loss of natural areas used for hunting, trapping, and gathering. Construction staging and active work zones may temporarily restrict community access to these areas, potentially during important seasons for traditional activities.

There may be increased competition for local resources if construction workers engage in hunting, fishing, or gathering, placing additional pressure on fish and wildlife populations. Habitat disturbances, noise, and increased human activity could alter wildlife movement patterns, affecting resource availability for the community.

Foraging and plant harvesting, activities central to the roles of women, youth, and Elders, could be affected. For example, the disturbance of wild blueberry harvesting sites, a key resource for Aroland First Nation, could affect both cultural practices and economic opportunities. The Aroland Youth Blueberry Initiative, which focuses on cultural continuity and economic development, may face challenges if traditional harvesting areas are disturbed or overharvested by non-community members. If programs such as the Aroland Youth Blueberry Initiative experiences setbacks, this may further affect the community's economic and cultural sustainability.

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming, and Long Lake #58 First Nations, face similar risks and potential negative effects to their traditional economies as those identified for Marten Falls First Nation and Aroland First Nation community members. Potential effects include reduced access to hunting and trapping areas and disturbance of wildlife such as moose and caribou. These changes threaten subsistence practices, fur trading, and other potential commercial activities. Disruptions to these systems could erode food security, intergenerational knowledge transfer, and the economic resilience of these communities.

Use of Traditional Language

Between 2016 and 2021, language use fluctuated in both communities, with a decline in Ojibway speakers in Marten Falls First Nation and a slight increase in Aroland First Nation. The overall concern about decline in use of traditional languages remains, particularly in environments dominated by English. While most community members

speak English, fluency levels vary, and for some members, traditional languages are their first language. In construction-related jobs, workers may feel pressure to speak only English, leading to reduced use of traditional languages in the workplace. This could be due to the use English in technical and safety communications, the presence of non-Indigenous workers, or a workplace culture that does not actively support multilingualism.

As a result, there may be a effect of reduced use of traditional language over time, contributing to language loss, particularly among younger workers who might already have limited fluency. As highlighted during community consultations, supporting use of traditional languages should be considered during project development. Women, especially Elders, are crucial to preserving language, and discouraging younger generations from using Ojibway in the workplace may increase the burden on women to maintain it within families and communities. Additionally, language barriers could limit economic opportunities for women, particularly if traditional language speakers face challenges in accessing employment or leadership roles in construction and resource industries.

9.5.6.3.6.2 Mitigation and Enhancement Measures

Traditional Economy

Mitigation measures for Traditional economy include:

- Prior to construction, owner / operator will develop Access Management Plans with Marten Falls First Nation and Aroland First Nation in relation to hunting, trapping and gathering activities. All activities must conform to licensing requirements and adhere to the rules and regulations under the Ministry of Natural Resources. This plan may include, but not be limited to:
  - Identifying key traditional hunting, trapping, and gathering areas to avoid, to minimize construction disturbance during peak harvest seasons.
  - Designating specific, approved locations for berry picking and recreational fishing for non-Indigenous workers while identifying restricted areas to protect community resources and minimize disturbance.
- Owner / operator to provide flexible work schedules for First Nation members during key hunting, trapping, and gathering seasons to support continued access to traditional food sources.
- Owner / operator to sponsor community-led harvesting initiatives in Marten Falls First Nation and Aroland First Nation.

- Owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including where to appropriately locate safety pull out areas to promote access, and other harvesting issues.
- Enhancement measures for Traditional Economy that can be further explored during detail design include:
  - Owner / operator to consider employment opportunities for First Nation community members as guides for construction workers participating in permitted outdoor activities.
  - Owner / operator to source traditional foods for work camps when possible, supporting local harvesters and small businesses, for example the Aroland First Nation Blueberry Initiative.
  - Owner / operator to consider supporting women-led initiatives, such as traditional food workshops or Indigenous-run catering services, to create economic benefits while reinforcing cultural identity.

Participation in Cultural Activities

Enhancement measures that could be further explored during detail design for participation in cultural activities in the community include:

- If pull-out areas are identified along the route for safety, these could be enhanced to include picnic tables, a fire pit, and an opportunity to use a non-plumbed restroom (outhouse). The meeting point could include safety measures that would have to be further explored logistically, that could include an emergency phone, or establish a cell tower to receive cell service, and have solar-powered lights.

Use of Traditional Language

Mitigation measures for change in use of traditional language include:

- Owner / operator to provide Training and Work Materials in Indigenous Languages. Offer onboarding materials, safety protocols, and job-related paperwork in Indigenous languages alongside English to provide language accessibility for all workers.
- Owner / operator to implement multi-lingual worksite signage. Reduce language barriers at the worksite by using multi-lingual signage at work sites, including directional signs, safety notices, workplace policies, and equipment labels, to promote the use of Indigenous languages in the workplace.

- Owner / operator to provide Cultural Sensitivity and Language Awareness Training. Educate non-Indigenous supervisors and workers on the importance of Indigenous languages in cultural identity, knowledge transmission, and community well-being. Encourage an inclusive workplace where traditional language use is supported and valued.
- Owner / operator to implement a Zero-Tolerance Policy for Language Discrimination. Establish clear workplace policies that prevent Indigenous workers from being discouraged from speaking their traditional language. Supervisors and project managers should actively reinforce language inclusivity and address any instances of discrimination or bias.
- Owner / operator to introduce a cultural safety mechanism. Introduce a workplace mechanism, such as a cultural safety flag, allowing employees to pause work or request support if they feel uncomfortable due to language-related issues. Propose a Cultural Safety and Stop Work Protocol.

Enhancement measures for change in use of traditional language include:

- Owner to consider incorporating Indigenous language in signage along the road. During detail design with Marten Falls First Nation and Aroland First Nation, should explore naming key landmarks, stopping points, and significant locations along the road in Indigenous languages to promote language visibility and daily use.
- Owner / operator to encourage traditional language use in informal work settings. Promote the use of traditional greetings and phrases in the workplace. Create spaces for Indigenous language speakers to communicate in their language during breaks or informal settings.
- Owner / operator to consider designating dedicated gathering spaces in construction camps for cultural exchange and knowledge transfer.
- Owner / operator to consider efforts to enhance language transmission, such as providing funding or resources to support language education, intergenerational learning, and community-driven cultural revitalization initiatives, could help preserve traditional language in both Marten Falls First Nation and Aroland First Nation.

9.5.6.3.6.3 Predicted Residual Effects

Traditional Economy

Despite mitigation measures, there remains some **low** magnitude, effects are **negative** in direction**.** Effects include a **possible** shift from traditional economy activities due to

loss of traditional harvesting areas or disturbance in the local Construction Disturbance Area. This could reduce available land for traditional activities within the project footprint, but uncertainty is **high**. Once operational, the road may improve access to new areas (as discussed in the Operations section).

During construction, **frequent** and **medium-term** disruptions to traditional land use are anticipated due to active work zones and **irreversible** land disturbance. While mitigation measures aim to minimize these effects, some access restrictions during key harvesting periods are likely.

The residual effects remain for the Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake First Nation, Neskantaga First Nation, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming First Nation, and Long Lake First Nation.

Participation in Cultural Activities in the Community

No residual effects during construction.

Use of Traditional Language

No residual effects are anticipated during construction, with proper implementation of mitigation measures.

9.5.6.3.7 Community and Public Health

9.5.6.3.7.1 Potential Effects

Mental Health and Well-being

The construction of the Community Access Road may have both positive and negative effects on the mental health and well-being of community members, primarily through employment opportunities, workplace conditions, and broader social dynamics within the community.

A potential **positive** effect is improved mental well-being due to employment in construction which can enhance financial stability, self-sufficiency, and pride, reduce financial stress, boost confidence, and build self-efficacy. Work force participation can lead to positive social interactions, teamwork, and professional development through training and experience, increasing individuals' self-esteem, strengthening internal and external relationships. Participating in the work force can create positive role models, inspiring younger generations through local employment success in construction.

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming, and Long Lake #58 First Nations, may experience similar positive effects from the Project.

Construction may also have a negative effect on mental health and well-being due to long hours, tight deadlines, and physically demanding tasks, leading to stress and fatigue. Working in a diverse cultural environment, particularly alongside non-Indigenous workers, could add challenges if cultural differences and language barriers are not addressed. High potential for Indigenous employees to experience micro aggressions, leading to elevated stress levels may result in high turnover, absenteeism, or workplace tensions if workers feel unsupported or struggle to adapt.

There is potential for social disconnection and emotional strain, as community members employed in construction may need to spend extended periods away from their families, leading to emotional distress, loneliness, and isolation.

Additionally, mental health and psychosocial well-being may be affected by increased sensory disturbances and restricted land access. Activities such as clearing, blasting, and heavy equipment operation introduce noise, dust, and visual changes that can disrupt the sense of place and diminish the quality of land-based experiences. For Indigenous communities, these changes can lead to feelings of disconnection and ecological grief, particularly when culturally significant areas are altered or temporarily inaccessible. The heightened industrial presence during construction may also exacerbate stress for individuals already facing mental health challenges, such as elevated suicide rates and addictions, by reducing opportunities for land-based healing and cultural practices.

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming, and Long Lake #58 First Nations, face similar risks and potential negative effects to their mental health and well-being as those identified for Marten Falls First Nation and Aroland First Nation community members. Potential effects include increased pressure from employment stress, community tension from employment disparities, and mental health and well-being effects related to changes to the land.

Substance Use

The introduction of a temporary work force into a remote First Nation community with no prior road access may have a negative effect of increasing alcohol and drug use. Construction workers may bring in prohibited substances, contributing to potential substance misuse issues within the community. Increased access to alcohol and drugs could affect vulnerable populations, such as youth and individuals recovering from

substance dependence, leading to social and health challenges like family disruptions and addiction-related concerns. An increased availability of alcohol and drugs could have social effects on Elders who may be at risk due to potential abuse or neglect within the family unit, while women and girls, especially those in caregiving roles or experiencing domestic violence, could face increased vulnerability. An increased presence of alcohol and drugs could negatively affect sexual health among as substance misuse can increase the likelihood of unsafe sexual practices, raising the risk of sexually transmitted infections or unwanted pregnancies.

Substance use within the work force may compromise workplace safety, leading to a higher risk of accidents, absenteeism, and reduced productivity. Impairment on the job could pose serious risks in a construction setting, particularly in operating heavy machinery or working in hazardous conditions. For community members employed in construction, exposure to workplace substance use could normalize unhealthy coping mechanisms for stress and fatigue, potentially leading to increased substance use among workers.

Road construction, especially in remote locations, is physically demanding and time-sensitive, requiring workers to endure long hours in harsh weather conditions. The stress of meeting deadlines and maintaining safety standards can lead to mental fatigue contributing to mental health concerns like anxiety or depression. This emotional strain may increase the likelihood of substance use as a coping mechanism. Additionally, the intense physical labour, including excavation, grading, and operating heavy machinery, can lead to physical exhaustion. Some workers, particularly men, may resort to alcohol or drugs to manage the discomfort, escape from isolation, or unwind after long, grueling workdays.

9.5.6.3.7.2 Mitigation and Enhancement Measures

Mental Health and Well-being

Mitigation measures to address potential negative effects on mental health, well-being, and employment challenge include:

- Owner / operator to collaborate with Marten Falls First Nation and Aroland First Nation to provide mental health counseling, mentorship, and peer support at work camps, with onsite Elders or cultural liaisons to promote emotional and cultural well-being, support skill development and workplace adjustment.
- Owner / operator to implement a gradual work force integration for community members, introducing shorter workdays and shift rotations (for example, starting with 2 to 3 days on with a day or two break instead of 10 consecutive days) to ease new workers into construction roles.

- Owner / operator to provide cultural safety training for all workers, including supervisors and non-Indigenous employees, to complete training on Indigenous culture, traditions, and historical experiences, to promote a safe and inclusive work environment.
- Owner / operator to hold training session on violence and harassment prevention.
- Owner / operator to enforce a zero-tolerance policy for workplace discrimination so that Indigenous workers feel respected and included.

Enhancement measures to enhance overall mental health and well-being include:

- Owner / operator to offer flexible work schedules to accommodate family responsibilities and cultural activities, which may reduce employee stress and to improve employee retention. This can include:
  - Family related leave where shift adjustments may be requested for family emergencies or events (for example, funerals, childcare).
  - Leave for participation in cultural activities, such as the annual pow wow, traditional harvest, or ceremonies.
  - Shift flexibility for employees to swap shifts or adjust work hours to accommodate personal needs.
- Owner / operator to designate a local hiring liaison to support Indigenous hiring, match skills with job opportunities, and to advocate for community member's needs.

Substance Use

Mitigation measures to address risks of substance use include:

- The owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, which could include topics in relation offering mental health supports, counselling and addiction support services.
- All construction workers (including on- and off-reserve members) will be housed in autonomous work camps to limit demographic shifts and limit disruptions to social structures and community dynamics.

- The owner / operator to develop and implement monitoring and enforcement, including regular security checks at work camps and entry points (for example, airport) for alcohol and substances to prevent entry into the community.
- Owner / operator to collaborate with the community (Marten Falls First Nation and Aroland First Nation) to provide mental health counseling, addictions counseling, mentorship, and peer support at work camps, with onsite Elders or cultural liaisons to promote emotional and cultural well-being.
- Owner / operator to enforce a zero-tolerance policy for alcohol and substance use at work camps via mandatory onsite alcohol and drug testing.
- Owner / operator to implement a gradual work force integration for community members, introducing shorter workdays and shift rotations (for example, starting with 2-3 days on with a day or two break instead of 10 consecutive days) to ease new workers into construction roles.
- Owner / operator to provide cultural safety training for all workers, including supervisors and non-Indigenous employees, to complete training on Indigenous culture, traditions, and historical experiences, to promote a safe and inclusive work environment.
- Owner / operator to hold training session on violence and harassment prevention.
- Owner / operator to enforce a zero-tolerance policy for workplace discrimination so that Indigenous workers feel respected and included.
- Owner / operator to provide cultural and recreational activities (for example, cards, board games, sports), when possible, to promote well-being and reduce boredom or stress-related substance use.

9.5.6.3.8 Access to Clean Water

9.5.6.3.8.1 Potential Effects

Access to Clean Water

The construction of a Community Access Road may have a negative effect on Marten Falls First Nation and Aroland First Nation of increasing demand for drinking water due to the presence of workers and additional infrastructure needs. If the local supply is insufficient, the communities may become more reliant on bottled water flown in. This assumes the water treatment plant remains non-operational. These factors could strain local resources. Construction activities may also cause an indirect effect of increasing the cost of water, including bottled water delivered into community during the boil-water

advisory, adding add financial pressure on both the First Nation communities and the Project.

Quality of Drinking Water

The quality of surface water may be affected by construction activities. An assessment of the quality of surface water can be found in the Problem Formulation for Human Health Risk Assessment (Appendix T). Potential effects on human health may be from chemical exposures through the consumption of contaminated water or through dermal absorption (through the skin) during recreational activities, bathing, or other direct contact. Volatile substances in water may be inhaled during activities such as cooking and bathing. Construction activities that may affect surface water quality include:

- Clearing the right-of-way for the Community Access Road and supporting access roads;
- Blasting rock;
- Construction of the Community Access Road;
- Construction and installation of bridges and culverts; and
- Construction and operations and decommissioning of temporary infrastructure

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Attawapiskat, Kashechewan, and Fort Albany First Nations, face similar risks and potential negative effects to quality of surface water as those identified for Marten Falls First Nation and Aroland First Nation community members.

9.5.6.3.8.2 Mitigation and Enhancement Measures

Access to Clean Water

Mitigation measures to access clean drinking water include:

- All construction workers, including on- and off-reserve members, will be housed in autonomous work camps, reducing pressure on community water resources.
- Owner / operator to implement temporary water storage tanks or other measures to accommodate peak water demands during construction, reducing reliance on flown-in water and helping to balance the construction and community needs. Aligning water delivery schedules, using water-efficient equipment, and coordinating bulk water orders, to mitigate any effects on the community's water supply.

Enhancement measures include:

- Owner / operator to promote water conservation strategies within the construction camps, including education on water-saving techniques and encouraging sustainable water usage habits for example low flow / water saving faucets.

Quality of Drinking Water

- Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Attawapiskat, Kashechewan, and Fort Albany First Nations, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including concerns related to quality of surface water.
- Waste, fuel, and hazardous materials will be handled under approved plans with spill prevention measures—following strict environmental standards and regulations, and continuous monitoring will confirm compliance and address any unexpected changes in water quality.

9.5.6.3.8.3 Predicted Residual Effects

Access to Clean Water

The indirect of increased water costs will be negligible, and any potential strain on transportation logistics for water delivery will be managed effectively, so that the community continues to receive its necessary water supply without disruption. There are no anticipated adverse effects on access to clean water if proactive mitigation measures and coordination between the construction activities and the community's water supply needs are implemented.

Quality of Drinking Water

Construction activities may result in negative residual changes to surface water quality and sediment quality from surface runoff and releases of suspended solids, chemical, biological and physical contaminants and physical disturbance and debris. Additionally, the deposition of particulate from air emissions and dust generated during construction and operations activities may also negatively affect surface water and sediment quality.

9.5.6.3.9 Traditional Foods

9.5.6.3.9.1 Potential Effects

Access to Traditional Foods

The construction of the Community Access Road may have a **positive** effect on the access to traditional food in Marten Falls First Nation and Aroland First Nation. Increased income from construction jobs could help community members purchase equipment, fuel, and supplies for hunting and trapping, support traditional harvesting, and increase access to traditional goods. The effect of the Community Access Road on traditional foods are further explored in the Aboriginal Treaty Rights and Interests assessment.

Availability of Traditional Foods

Construction activities, including land clearing for the road corridor, work camps, and pits and quarries, may have a effect due to disturbances that reduce the availability of some traditional foods during key harvest seasons.

Quality of Traditional Foods

Construction activities may disturb local ecosystems and reduce the quality of traditional foods during important harvesting periods. These activities include land clearing for the road corridor, work camps, and material source areas. Residual effects on surface water, groundwater, air, soils, peatlands, and noise levels can influence environmental conditions in both the Local and Regional Study Areas, which in turn may affect the condition of fish, vegetation, birds, and ungulates used as traditional foods. When traditional foods are harvested from affected areas, contaminants may pose direct risks to people who consume them.

Indigenous communities with overlapping interests in the Local Study Area which include Constance Lake First Nation, Fort Albany First Nation, Attawapiskat First Nation, Kashechewan First Nation, Kasabonika Lake First Nation, Kitchenuhmaykoosib Inninuwug First Nation, Kingfisher Lake First Nation, Eabametoong First Nation, Mishkeegogamang First Nation, Neskantaga First Nation, Nibinamik First Nation, Wapekeka First Nation, Wawakapewin First Nation, Webequie First Nation, Weenusk First Nation, Wunnumin Lake First Nation, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming First Nation, and Long Lake #58 First Nation may face similar potential **negative** effects related to the quality and availability of some traditional foods as those identified for Marten Falls First Nation and Aroland First Nation.

9.5.6.3.9.2 Mitigation and Enhancement Measures

Access, Availability and Quality of Traditional Foods

Mitigation measures to mitigate the potential effects on the accessibility, availability and quality of traditional foods include:

- Owner / operator should provide flexibility in work schedules during key hunting, trapping, and gathering seasons to support continued access to traditional food sources.
- The owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation, and other affected Indigenous communities, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road to identify key harvesting areas to implement measures that can minimize construction disturbances and contamination to traditional food resources during harvesting seasons. This may include adjusting construction activities to avoid peak harvesting periods.

9.5.6.3.9.3 Predicted Residual Effects

Access to Traditional Foods

If mitigation measures are implemented there is anticipated to be minimal to no adverse residual effect on the accessibility of traditional foods because of the increased flexibility for community members to balance employment and traditional harvesting.

Availability of Traditional Foods

There is a **negative** effect on the availability of traditional foods, due to disturbances from construction activities, that may not be fully mitigated. This effect is **possible**, expected to be of **low** magnitude, **local** and **short-term**. The effect may be **infrequent** and **reversible**, and has a **high uncertainty.**

Quality of Traditional Foods

The quality of fish, vegetation, wildlife, birds, and ungulates as a traditional food is dependent on the quality of their habitat or namely the surface water, air and soil quality to which they are exposed. Effects from soil contamination leaching, emissions of criteria air contaminants and deposition to surface water, changes to erosion and sedimentation, changes to surface water quality, dust deposition, and increased public access to fish have the potential to affect the quality of fish, vegetation, wildlife, birds, and ungulates as country foods and potentially affect human health.

There is also a possible effect on the quality of traditional foods, due to contamination from construction activities that may not be fully mitigated. This effect is expected to be of **moderate** magnitude, **local,** and **short-term**. The effect may be **infrequent, irreversible**, with a **high** uncertainty.

These residual effects on the availability and quality of traditional foods apply to the Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake First Nation, Fort Albany First Nation, Attawapiskat First Nation, Kashechewan First Nation, Kasabonika Lake First Nation, Kitchenuhmaykoosib Inninuwug First Nation, Kingfisher Lake First Nation, Eabametoong First Nation, Mishkeegogamang First Nation, Neskantaga First Nation, Nibinamik First Nation, Wapekeka First Nation, Wawakapewin First Nation, Webequie First Nation, Weenusk First Nation, Wunnumin Lake First Nation, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming First Nation, and Long Lake #58 First Nation may face similar potential negative effects related to the quality and availability of traditional foods as those identified for Marten Falls First Nation and Aroland First Nation.

9.5.6.3.10 Public Safety

9.5.6.3.10.1 Potential Effects

Drivers Licence

During construction, employment opportunities in road building will increase, particularly in roles such as truck driving, equipment operation, and material transport. Holding a valid driver's licence will be required for many community members to access onsite and community-based jobs. This is likely to increase demand amongst individuals in both Marten Falls and Aroland First Nation to hold a valid Driver's Licence. However, there are barriers to community members obtaining a driver's licence, such as the cost of travel to urban centres, challenges in completing the necessary assessments, and difficulties accessing required documentation. Unless barriers are addressed, there is likely to be the effect that demand for workers with Driver's licences exceeds those available, thereby limiting the community benefits of the Project.

Road Safety

Construction will have an effect road safety due to traffic of heavy machinery, construction vehicles, and material transport on the winter road to Marten Falls First Nation. Local residents traveling on the same road may be at risk, especially when large vehicles such as trucks and construction equipment share the road. The increased vehicle movement heightens the potential for accidents, particularly in areas with narrow or poorly maintained road segments. Traffic congestion on these narrow or difficult-to-

navigate sections could increase the risk of collisions, especially with large construction vehicles. Inadequate signage and unfamiliarity with the route further elevate the risk for workers or truck drivers not accustomed to traveling on the winter road.

Emergency Services

The construction of the Community Access Road is expected to have an effect on emergency services due to higher risks of potential workplace injuries, vehicle accidents, and other construction-related incidents. As a result, emergency response teams serving Marten Falls First Nation and Aroland First Nation may experience a higher number of service calls related to construction site injuries and traffic incidents. This could divert resources from responding to other emergencies in the communities, potentially delaying access to timely medical care for residents.

Severe injuries requiring advanced medical treatment may need medical evacuations to Thunder Bay or other regional hospitals. A higher frequency of medical transports may place additional pressure on limited local resources responsible for coordinating medical flights, further delaying or reducing emergency services for community Women, Elders, and caregivers may face greater challenges accessing emergency services, such as maternal health, chronic illnesses, or Elder care, if local resources are strained due to construction-related incidents.

An increase in emergency response demands may result in the indirect effect of increased demands on community health service workers, who provide administrative, operational, maintenance, and prevention-focused care through programs such as Building Healthy Communities, the Aboriginal Diabetes Initiative, and the National Native Alcohol and Drug Abuse Program. Increased pressure on these workers could reduce the capacity to deliver essential services such as maternal and child health programs, mental health support, and preventative care.

Violence and Harassment

The construction of the Community Access Road may have an effect of increasing violence and harassment within the community, particularly with the presence of outside workers and the interaction between these workers and community members.

The presence of outside workers may increase aggression or disruptive behaviour, intensified by cultural differences, lack of familiarity with the community, and challenges in integrating into the local social fabric. An influx of workers, especially if the work force is primarily from outside the community, may increase risks of racial, ethnic, or gender-based harassment of Indigenous community members, particularly women and gender-diverse individuals. This could include verbal abuse, inappropriate behaviour, or

physical harassment and may be compounded by power dynamics of non-community workers and local residents.

If some individuals are excluded from construction-related employment, this may have the indirect, negative effect of increasing lateral violence, conflicts among Indigenous community members, verbal or physical altercations, rumours, or social divisions, ultimately disrupting community cohesion and furthering social tensions.

These risks, ranging from interpersonal conflict and harassment to domestic strain and community fragmentation, create conditions in which gender-based violence may become more prevalent. Gender-based violence refers to harmful acts rooted in gender inequality and power imbalances, disproportionately affecting women, girls, and gender-diverse individuals. In the context of the Community Access Road, the presence of outside workers, cultural and social tensions, and economic disparities may intensify vulnerabilities among Indigenous community members, particularly women and gender-diverse people. Prolonged shift work and separation from family may increase marital strain, potentially leading to higher instances of domestic violence or family breakdown. Communication challenges between partners, particularly in the context of work-related stress, can intensify these issues. Recognizing and addressing these risks is essential to safeguarding community well-being so that mitigation strategies are inclusive, culturally sensitive, and trauma informed.

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming, and Long Lake #58 First Nations, as well as regional municipalities Thunder Bay and Greenstone face similar risks and potential negative effects related to increases in violence and harassment.

9.5.6.3.10.2 Mitigation and Enhancement Measures

Driver's Licence

To the barriers to obtaining a driver's licence in Marten Falls First Nation, the following mitigation measures should be further explored in detail design to increase the number of local Driver Licence holders:

- Owner / operator and owner of the road to explore opportunities to increase total Driver Licence holders, alongside the Ministry of Transportation, partnering with organizations such as:
- Kiikenomaga Kikenjigewen Employment and Training Services, or other trusted organizations, to offer driving training programs to support community members in passing their assessments;

- Third-party organizations that provide drivers licence testing for remote communities.

Road Safety

Mitigation measures to support road safety during construction include:

- Owner / operator will develop an Equipment Mobilization Plan with both Marten Falls First Nation and Aroland First Nation for the movement of equipment, personnel, supplies, and resources. Where possible, construction traffic should be separated from community traffic to improve safety and minimize disruptions. The mobilization plan should also include a clear communications strategy to keep the community informed of the mobilization schedule, making residents aware of periods of increased heavy equipment traffic on the winter road. The plan should include the following components:
  - Weight restrictions. Implement weight restrictions for loads to road damage and confirm safe transport.
  - Designate transport times. Work to establish transport peak periods suitable for the First Nation, where possible.
  - Establish communication protocols. Establish and maintain clear communication with surrounding communities, providing advanced notice of transport schedules and real-time updates on road conditions.
  - Peak hour avoidance. Schedule heavy equipment transport outside of peak community traffic hours.
  - Use pilot vehicles to escort large or heavy equipment when necessary to guarantee safe passage.
- Owner / operator to implement mandatory driver safety training for all employees. This could include training tailored to winter road conditions and remote community travel.

Emergency Services

Mitigation measures for emergency services include the following:

- Owner / operator must develop an onsite safety and emergency preparedness program to include:
  - Implement onsite fire suppression systems, including sprinklers and fire extinguishers, to minimize reliance on local fire services.

  - Provide onsite medical care (paramedics, first aid stations, medics) to reduce pressure on local emergency response services.
  - Train and employ onsite security personnel to monitor safety compliance and enforce safety policies, reducing the strain on local police.
  - Work with the Ministry of Health and other appropriate government agencies to develop a coordinated emergency response plan with local responders for efficient handling of construction-related incidents requiring additional personnel.
  - Establish clear communication protocols between the construction teams and local emergency responders.
- Owner / operator r must compliance with Ontario's *Occupational Health and Safety Act* (Ontario, n.d.a). The owner / operator will adhere to all relevant health and safety requirements, including (but not limited to):
  - Preparation of a Health and Safety Policy covering:
    - Worker safety training (for example, WHMIS, new job procedures)
    - Workplace hazard analysis and incident investigations
    - Communication and feedback mechanism for worker safety concerns
    - Emergency procedures, first aid and rescue procedures
    - Engineering, administrative, and personal protective equipment controls. Enforcement of Stop Work Policies if unsafe conditions are identified

Implementing these measures will minimize accident risks, so that the continued availability of emergency medical flights for non-construction-related community needs, such as medical evacuations for high-risk patients (for example, pregnant women, Elders, and individuals with chronic conditions).

Violence and Harassment

Mitigation measures for violence and harassment include the following:

- Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities and municipalities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road including:

- Financial literacy programs for workers and families to help manage income fluctuations and reduce financial stress, addressing economic disparities that could contribute to resentment and lateral violence.
- Measures to strengthen cultural programming and land-based activities to reinforce community cohesion and well-being. Strengthening cultural identity and offering community-driven programs can provide positive coping mechanisms for workers and families experiencing stress due to shift work and can offer a protective factor against violence and social disruption by strengthening support networks and reducing isolation, support for unemployed community members by identifying employment barriers and offering job readiness programs to support community members facing unemployment.
- All construction workers, including on- and off-reserve members, will be housed in autonomous work camps to limit unsupervised interactions with the community, reducing the risks of harassment, social conflict, and misconduct. The owner / operator will prioritize gender-divided living quarters in the workcamps, offering structured environments with oversight to minimize opportunities for violence or inappropriate behaviour.
- The owner / operator will enforce a zero-tolerance policy towards harassment, discrimination, and violence in work camps and on construction sites with strict enforcement and disciplinary actions in compliance with Ontario's *Occupational Health and Safety Act* (Ontario, n.d.a), it will include:
  - Clear anti-harassment policies defining unacceptable behaviour and consequences.
  - Mandatory reporting mechanisms for safe, confidential reporting of harassment or violence.
  - Third-party oversight for transparency and for unbiased investigations and enforcement. Deliver a violence and harassment training session for employees.
- Owner / operator to provide cultural safety and language awareness training for all workers, including supervisors and non-Indigenous employees, to complete training on Indigenous culture, traditions, and historical experiences to understand Indigenous cultural norms and appropriate community interactions to reduce instances of harassment or violence.
- The owner / operator will comply with the Human Rights Code (Ontario, 2024b) to prevent workplace discrimination and uphold employee rights to reduce work force tensions.

- The owner / operator will provide mental health counseling, mentorship, and peer support at work camps to reduce stress-related aggression. On-site Elders or cultural liaisons will offer emotional support and traditional guidance to workers, helping to address conflicts before they escalate into violence or harassment.
- The owner / operator will implement a gradual work force integration for community members, starting with shorter workdays and shift rotations (for example, 2-3 days on, followed by a break) to reduce workplace stress and minimize the potential for lateral violence, burnout, and community tensions.
- Owner / operator to implement Diversity, Equity, and Inclusion hiring policy which can contribute to a more balanced work force and reduce the risks of harassment in male-dominated work environments.

9.5.6.3.10.3 Predicted Residual Effects

Drivers License

No adverse residual effects are anticipated, provided mitigation measures are implemented to support community acquisition of Driver's Licences.

Road Safety

Even with mitigation measures, likelihood is **probable** that the increased traffic during construction could lead to an increased risk of accidents. This could include serious incidents such as trucks or heavy equipment breaking through the ice on the winter road. These **negative** effects are anticipated to be **moderate** in magnitude, **infrequent**, **reversible**, **short-term**, with **low uncertainty**, given the limited duration of the winter road use during construction.

Emergency Services

Even with the proposed mitigations, it is **possible** there will be **negative** effects, increasing pressure on emergency services within the Local Study Area. With proper onsite emergency management, including onsite medical personnel and coordination with local emergency services, major disruptions to emergency response in Marten Falls First Nation and Aroland First Nation are not expected. However, despite the presence of onsite medical staff, certain injuries or health concerns may still require transport to community health facilities in Marten Falls First Nation. This could lead to short-term increases in demand for the local nursing station and medevac services. While mitigation measures will reduce workplace injuries, some serious cases may still require evacuation to regional hospitals, such as Thunder Bay. This may place some additional demand on local emergency response and coordination services, though

effects are expected to be **moderate** and **infrequent**. These pressures are expected to be **local, short-term, reversible,** with **low uncertainty**.

Violence and Harassment

While mitigation measures will reduce risks of violence, harassment, and family strain, they may not eliminate them entirely for Local Study Area communities, Indigenous communities with interests in the Local Study Area or for regional municipal communities of Thunder Bay and Greenstone. It is **possible** that **negative** residual effects are expected to include occasional workplace conflicts, ongoing family stress from shift work, and potential lateral violence due to economic disparities, with **low uncertainty**.

Predicted residual effects after mitigation include:

- Violence and harassment between workers and community members is expected to be low risk after mitigation. Work camps will limit direct interactions between works and the community, and mandatory training will promote respectful behaviour, but occasional conflicts may still occur.
- Lateral violence within the community may persist at a low to moderate levels, with some individuals feeling excluded from economic opportunities, potentially leading to resentment and social tensions.
- Workplace harassment and discrimination will be reduced but not entirely eliminated. Training and zero-tolerance policies will help prevent incidents, but ongoing oversight and enforcement will be needed to address any incidents.
- Family and relationship strain due to shift work may lead to stress-related conflicts. Although shorter shifts and financial literacy training may help, prolonged separations may still cause tension within households, potentially increasing domestic disputes.
- Emotional strain and burnout among workers may continue despite mental health supports. On-site Elders, cultural liaisons, and peer support programs will provide relief, but the demanding nature of construction work, isolation in work camps, and shift work pressures may still contribute to stress-related conflicts or frustration-driven workplace tensions

Continued investment in mental health, family support, and economic opportunities will be essential for long-term well-being. With sustained collaboration between the community and owner / operator, these effects can be managed over time as they are anticipated to be **local, short-term, moderate** in magnitude and **reversible**.

9.5.6.3.11 Biophysical Determinants to Human Health

9.5.6.3.11.1 Potential Effects

A summary of contaminant release during construction and their potential to affect the environment influencing human health has been included for each biophysical indicator.

For the purpose of this assessment, changes to the quality of the environment where country foods are harvested will be used to evaluate the potential residual effects associated with project-related activities that may affect the quality of these foods. Biophysical determinants to human health may be affected by chemical exposures through the consumption of contaminated country foods, depending on the type, magnitude, and frequency of exposure. Further information on potential effects is included in the Problem Formulation in **Appendix T** of Community Well-Being Technical Support Document [Appendix T].

Air Quality

A summary of contaminant releases during construction and their potential to affect the environment influencing human health include:

- Potential effects on human health may result from chemical exposures through the inhalation of volatile contaminants, particulate material, and the ingestion of inhaled dust. Air quality will be affected during the construction of the Project. Chemicals of particular concern for air quality include nitrogen dioxide, total suspended particulates, particulate matter less than 10 micrometers, particulate matter less than 2.5 micrometers, sulphur dioxide, carbon monoxide, acrolein, benzo(a)pyrene, diesel particulate matter and dust deposition. Construction activities that may affect air quality include:
  - Quarry blasting and operation
  - Burning and clearing
  - Bridge building
  - Community Access Road construction
  - Aggregate operations
  - Emissions of volatile substances (such as, burning of fossil fuels in vehicles and equipment)

Noise and Vibration

A summary of exposure during construction and their potential to affect the environment for noise and vibration influencing human health include:

- Biophysical human health may be affected by exposure to noise and vibration. Noise represents a distinct environmental change, as it introduces energy into air. Prolonged exposure to noise can lead to sleep disturbances and long-term high annoyance. Human responses to noise vary by individual sensitivity, the type of noise, and specific situations. The most common community reactions to noise include complaints and heightened annoyance. Construction activities that may affect noise and vibration include:
- Project construction activities including clearing, grading, earthmoving, grubbing, and stockpiling;
- Temporary access road reclamation and decommissioning;
- Construction of infrastructure including access roads, bridges, temporary laydown areas, turn-around areas and temporary construction camps; and
- Pit and quarry work.

Soil Quality

A summary of contaminant releases during construction and their potential to affect the environment for soil quality influencing human health include:

- Construction activities that may affect soil quality include:
  - Leaks and spills during equipment, supplies and personnel mobilization; and
  - Deposition of dust and air contaminant emissions from construction, blasting and mobilization activities.

Sediment Quality

A summary of contaminant releases during construction and their potential to affect the environment influencing human health include:

- Potential effects on human health may be affected from chemical exposures through the consumption of contaminated water or through dermal absorption (through the skin) during recreational activities, bathing, or other direct contact. Construction activities that may affect sediment quality include:
  - Clearing the right-of-way for the Community Access Road and supporting access roads;
  - Quarry blasting;
  - Construction of the Community Access Road;
  - Construction and installation of bridges and culverts; and
  - Construction and operations and decommissioning of temporary infrastructure.

Land Use

A summary of contaminant releases during construction and their potential to affect the environment influencing human health include:

- Potential effects on human health may be affected from chemical exposures through the consumption of contaminated water or through dermal absorption (through the skin) during recreational activities, bathing, or other direct contact. Volatile substances in water may be inhaled during activities such as bathing and cooking. Construction activities that may affect surface water quality include:
  - Clearing the right-of-way for the Community Access Road and supporting access roads;
  - Quarry blasting;
  - Construction of the Community Access Road;
  - Construction and installation of bridges and culverts; and
  - Construction and operations and decommissioning of temporary infrastructure.

Peatlands

A summary of contaminant releases during construction and their potential to affect the environment for peatlands influencing human health include:

- Within the Local Study Area, peatlands are existing sources of carbon dioxide and methane. Construction activities will remove portions of the wetland, reducing the amount of carbon dioxide and methane released by natural processes. Peatlands Technical Support Document (Appendix I).

Accidents and Malfunctions

A summary of contaminant releases during construction and their potential to affect the environment influencing human health include:

- Accidents and malfunctions can affect the quality of soils, sediment, surface water and groundwater, and therefore Country Foods. Potential effects on human health may be through chemical exposures through the consumption of contaminated water or through dermal absorption (through the skin) during recreational activities, bathing, or other direct contact. Construction activities which may affect soil, sediment, surface water and groundwater quality include:
  - Clearing the right-of-way for the Community Access Road and supporting access roads;
  - Blasting rock;

- Construction of the Community Access Road;
- Construction and installation of bridges and culverts; and
- Construction and decommissioning of temporary infrastructure.

9.5.6.3.11.2 Mitigation and Enhancement Measures

Mitigation measures to address biophysical factors influencing human health during construction include:

- Owner / operator to obtain all required permits, authorizations, and approvals prior to conducting specific construction activities.
- Owner / operator must comply with all applicable regulations, legislation, permit requirements, and best practices regarding all work.
- Owner / operator to develop and comply with Project specific Management and monitoring plans, including, but not limited to, a Construction Best Management Practice Plan, Blasting and Communication Management Plan, Erosion and Sediment Control Plan, Fugitive Dust Management Plan.
- Owner / operator should plan timing of construction activities to minimize environmental effects.
- An additional mitigation measure is also recommended to mitigate effects on human health:
  - The owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, including Animbiigoo Zaagi'igan Anishinaabek, Attawapiskat First Nation, Constance Lake First Nation, Fort Albany First Nation, Ginoogaming First Nation, Kashechewan First Nation, Long Lake #58 First Nation, and Neskantaga First Nation, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including concerns related to the biophysical effects on human health during construction, such as air, noise and vibration, sediment, soil, ground and surface water, and human land-use.

9.5.6.3.11.3 Predicted Residual Effects

To determine the magnitude and extent of residual effects of project construction activities on biophysical human health requires the modelling of predicted concentrations based on expected Project activities. For this Project, air concentrations during construction were the only aspect modelled. Residual effects to surface water, groundwater, soils, and sediment, including deposition of dust onto surface water soils

and sediment, were not fully evaluated in the individual technical studies, and modelling was not completed, and as a result, not all biophysical determinants residual effects characterizations can be predicated.

With the information available, the following adverse residual effects are predicted:

Air Quality - Possible, continuous, negative effects on air quality of high magnitude limited to the Construction Disturbance Area are predicted with high uncertainty. However, the air quality assessment determined no significant residual effects to human health, due to reversible and short-term duration of air quality effects from construction activities.

Noise and Vibration - Certain, negative effects of high magnitude due to blasting, quarrying, road construction noise are predicted residual effects, with low uncertainty. However, the noise and vibration assessment determined no significant residual effects to human health during construction as effects are predicted to be short-term and infrequent, reversible and limited to the Construction Disturbance Area. Additional details related to mitigations during construction can be found in the individual technical support documents.

9.5.6.4 Residual Effects – Operations Phase

9.5.6.4.1 Sustainable Population Growth

9.5.6.4.1.1 Potential Effects

Age Distribution

With the Community Access Road operational, improved transportation and access to services is likely to have the **positive** effect of gradually leading to a more balanced age distribution. Improved transportation access will make it easier for families to travel for employment, education, and services without permanently relocating. The road will not only improve local job opportunities but also allow parents to visit their high-school-aged children more frequently and at a lower cost, reducing disruption to family life.

For older adults, the road will enhance access to medical care, reducing the need for long-term relocation to urban areas. In remote communities, limited healthcare often forces Elders to move closer to hospitals and long-term care facilities. With year-round road access, individuals can travel for medical appointments and return home, leading to increased Elder retention and growing demand for in-community healthcare and Eldercare services.

All potential effects may contribute to a gradual shift from the current youth-dominated demographic toward a more balanced age distribution of children, working-age adults, and senior individuals. This predicated shift toward national or regional norms could support future community growth, economic development, and intergenerational knowledge transfer.

Community Population

The operation of the Community Access Road is expected to have a **positive** effect of increasing the community population in Marten Falls First Nation, Aroland First Nation and regional municipal communities of Thunder Bay and Greenstone. Engagement feedback indicates that some off-reserve members are interested in returning once year-round access is established. The new road access may attract both off-reserve members and external workers seeking employment in road maintenance, infrastructure development, and new businesses to Indigenous and regional municipal communities in the region. Families may be more likely to remain in these communities as their children reach high school age, as the road will allow for easier travel to visit students instead of requiring permanent relocation. Over time, this could lead to a stronger community identity and improved social cohesion as residents are able to live closer to family, traditional lands, and cultural resources.

9.5.6.4.2 Labour Market Dynamics

9.5.6.4.2.1 Potential Effects

Labour Force

Operations and maintenance spending is expected to total $11 million on average per year. As shown in the table below, about 30 direct jobs are expected to occur in Ontario during operations on average per year, which along with indirect and induced employment effects would result in about 80 jobs overall. This could lead to about 10 jobs in the rest of Canada, with a total of 90 jobs in Canada overall. These jobs can be filled with the existing labour force in Marten Falls First Nation, as well as the surrounding communities and districts.

These employment effects are expected to directly create about $2.0 million in Ontario's labour income, along with an indirect effect of $2.7 million and an induced effect of $0.8 million. This implies a total labour income effect of $5.5 million and an average labour income of around $68,200 per job. For Canada overall, the total labour income effect is $6.1 million, which gives an average labour income of about $68,300 per job. The expected total effect on Ontario's Gross Domestic Product is $9.9 million. This implies an average income produced of about $123,600 per job. On the other hand, the

expected total effect on Canada's Gross Domestic Product is about $11.2 million, which implies an average income produced of $125,600 per job.

Operations of the Community Access Road is anticipated to create a **positive** effect on educational attainment for Marten Fall First Nation. Road connectivity may support children pursuing secondary education in regions such as Geraldton or Thunder Bay.

Indirect effects related to labour market dynamics include:

- Indirect input-output effects are expected across the supply chain industries. When demand for a specific product or service increases, the industries supplying the necessary materials, labour, or support services also experience growth.
- Other general indirect effects could arise from people moving back to the community given the increase in economic activity and jobs. This increase in population and income would lead to higher demand, including the demand for housing.

9.5.6.4.2.2 Predicted Residual Effects

Labour Force

There are no significant adverse residual effects for the labour market dynamics during operations. There are potential **positive** residual effects on labour market dynamics through increased employment and training opportunities during operations.

Earnings

There are no significant adverse residual effects for the labour market dynamics during the operations.

Educational Attainment

Operations of the Community Access Road is anticipated to create a **positive** effect on educational attainment for Marten Fall First Nation.

9.5.6.4.3 Economy

9.5.6.4.3.1 Potential Effects

Local Businesses and Commercial Activities

Operations presents an ongoing opportunity for business development related to road operations. There could be potential services created during operations, such as establishing a community transportation system (shuttle bus or van), designed to

transport community members to medical appointments, grocery shopping, recreational opportunities and to ship goods and materials. This service would provide flexibility in scheduling, allowing for more efficient and reliable access to and from the community, and better coordination for essential travel needs. At the same time; however, barriers to new or expanding business opportunities during operations may still exist.

Indirect effects related to local businesses include:

- Indirect input-output effects occur in the supply chain due to industry linkages. When demand for a specific product or service increases, the industries supplying the necessary materials, labour, or support services also experience growth. If there is higher direct demand for some product in the economy, then the businesses in the industries supplying that product are indirectly affected.
- Other general indirect effects could arise from people moving back to the community given the increase in economic activity and jobs. This increase in population and income would lead to higher demand, including the demand for housing.

Public Finances

Considering all the economic activity across Canada, the total effect on tax revenue is expected to be $3.0 million during the operation phase. This is led by taxes on income ($2.0 million), mostly at the federal level ($1.2 million). Taxes on products are projected to be $0.6 million, with approximately half of that going to the local government, while taxes on production are expected to total $0.5 million, with $0.3 million going to the local government.

Indirect effects related to public finances include:

- Indirect effects occur in the supply chain due to industry linkages. When demand for a specific product or service increases, the industries supplying the necessary materials, labour, or support services also experience growth. If there is higher direct demand for some product in the economy, then the industries supplying that product are indirectly affected, which then leads to additional tax revenues.
- Other general indirect effects could arise from people moving back to the community given the increase in economic activity and jobs. This increase in population and income would lead to higher demand, including the demand for housing.

Regional Economy

Summary of the regional economic effects of the $11 million operation spending is shown in **Table 9.5-30** and **Table 9.5-31**, followed by sections for each economic indicator.

Table 9.5-30: Ontario Operation and Maintenance Effects

Ontario Operation and Maintenance Effects (millions of dollars)	Direct Effects	Indirect Effects	Induced Effects	Total Effects
Output	11.0	8.4	3.0	22.4
Gross Domestic Product	3.6	4.3	2.0	9.9
Labour Income	2.0	2.7	0.8	5.5
Gross Operating Surplus	1.5	1.5	0.9	3.9
Taxes on Products	0.1	0.1	0.3	0.5
Taxes on Production	0.2	0.2	0.2	0.5
Taxes on Income	0.6	0.8	0.3	1.7
Employment (jobs)	27	39	14	80

Source: Statistics Canada, 2026d, 2026e, 2026f, AECOM Analysis.

Table 9.5-31: Canada Operation and Maintenance Effects

Canada Operation and Maintenance Effects (millions of dollars)	Direct Effects	Indirect Effects	Induced Effects	Total Effects
Output	11.0	10.0	3.8	24.8
Gross Domestic Product	3.6	5.1	2.5	11.2
Labour Income	2.0	3.1	1.0	6.1
Gross Operating Surplus	1.5	1.9	1.1	4.5
Taxes on Products	0.1	0.1	0.3	0.6
Taxes on Production	0.2	0.2	0.2	0.5
Taxes on Income	0.6	0.9	0.4	2.0
Employment (jobs)	27	45	17	89

Source: Statistics Canada, 2026d, 2026e, 2026f, AECOM Analysis.

Output

As per **Table 9.5-30**, the $11 million operation and maintenance spending is expected to lead to total economic activity (output) in Ontario of $22.4 million on average per year. The total effects on output are estimated to be $24.8 million for Canada (**Table 9.5-31**).

Gross Domestic Product

As per **Table 9.5-30** Ontario's total economic value, measured by its Gross Domestic Product (income produced), is projected to be $9.9 million annually. Meanwhile, the

total effects on Canada's Gross Domestic Product are expected to be $11.2 million (**Table 9.5-31**).

Labour Income

As per **Table 9.5-30**, total effects on labour income are expected to be $5.5 million per year in Ontario. The total effects on Canada's labour income are estimated to be $6.1 million, with approximately half of those coming from the indirect effects (**Table 9.5-31**).

Gross Operating Surplus

As per **Table 9.5-30**, Ontario's gross operating surplus total effect is estimated to be $3.9 million annually. The estimated total effects on gross operating surplus are expected to be $4.5 million, with the indirect effects being the most dominant.

Taxes

As per **Table 9.5-30**, the total effects on taxes in Ontario ($2.7 million) are led by taxes on income ($1.7 million), followed by taxes on products ($0.5 million) and taxes on production ($0.5 million). The total effects on taxes in Canada are estimated to be $3.0 million (**Table 9.5-31**). This is led by taxes on income ($2.0 million), followed by taxes on products ($0.6 million) and taxes on production ($0.5 million).

Employment

Operations is expected to engage about 80 total jobs in Ontario, which includes around 30 direct jobs. The overall employment effect for Canada is expected to be around 90 jobs, with the indirect effects on employment being most prominent.

Indirect effects related to the regional economy include:

- Indirect input-output effects occur in the supply chain due to industry linkages. If there is higher direct demand for some product in the economy, then the industries supplying that product are indirectly affected. In the context of the Project, the operating spending for the new Community Access Road directly affects the support activities for transportation industry. The support activities for transportation industry makes the first round of indirect expenditures on its supply chain industries. Those industries will then make their expenditures on their supply chain industries. The sum of all those indirect effects gives the total indirect effects, as discussed earlier.

9.5.6.4.3.2 Mitigation and Enhancement Measures

Local Businesses and Commercial Activities

Mitigation measures to address potential business environment issues include:

- Owner / operator will implement Community Readiness Strategies and Adaptive Management Plans to assess and respond to community needs through construction and prepare for operations.
- Owner / operator will create a Local Content Plan to utilize a certain dollar value or share towards local businesses and contractors for operations.

Enhancement measures focused on improving the business environment include:

- Owner / operator should prioritize hiring Marten Falls First Nation and Aroland First Nation members, as well as other Indigenous community members.

9.5.6.4.3.3 Predicted Residual Effects

Local Businesses and Commercial Activities

There are no adverse residual effects for the business environment during the operations. Possible **positive** residual effects are anticipated on the economy through potential productivity improvements, land value uplift, and higher economic diversification.

Regional Economy

There are no significant adverse residual effects for the regional economy during operations. Possible **positive** residual effects are anticipated on the business environment through potential productivity improvements and higher economic diversification.

9.5.6.4.4 Community Access to Infrastructure and Services

9.5.6.4.4.1 Potential Effects

Methods of Transportation In and Out of the Community

The construction of a permanent Community Access Road will eliminate the Marten Falls First Nation's reliance on the seasonal winter road, which is limited by climate variability and short operational periods. Year-round access will eliminate reliance on flight schedules and the limited winter road, improving the predictability of available travel means for essential services, education, and employment opportunities. This will result in a **positive** effect of reliable, year-round, all-season road-access for people and

goods, increasing supply delivery and reducing the community's dependency on costly air transport.

The road will also reduce dependence on air transportation, having the indirect positive effect of improving access to goods, services, and supplies. Year-round road access will reduce travel costs considerably for community members, particularly families. With one tank of gas costing between $100-$200, compared to up to $2,120 for return flights for a family of four using ZAM Air out of Nakina, or $4,000 using North Star Air from Thunder Bay, the road provides major financial savings. The ability to make day trips to nearby towns like Geraldton or Nakina also eliminates the need for overnight accommodation costs. Road access also reduces the travel costs for out-of-community healthcare appointments, reducing this community cost. Food prices are also expected to decrease, easing the financial strain on community members, especially lower-income residents, who may otherwise face limited access to affordable, nutritious food. Reduced costs may help alleviate food insecurity, improve overall health outcomes, and support community well-being. For example, as of 2025, the price of a 10 kg bag of flour at Superstore in Thunder Bay ranges from $10.99 to $18.97, and $15.97 for a 10 kg bag of sugar. In contrast, communities like Neskantaga First Nation (and based on similar remote location to Marten Falls First Nation we can assume prices are similar) were paying $40 to $70 for a 10 kg bag of flour and $30 for sugar in 2023. These major price differences highlight the financial strain on community members, particularly lower-income residents, who are already facing limited access to affordable food options.

While these savings represent a direct positive benefit to all community members, members of the Gender-Based Analysis Plus groups, such as youth, single parents, lower-income earners, and Elders, will particularly feel the **positive** effects.

No direct effects on methods of transportation in or out of Aroland First Nation are anticipated.

Essential Infrastructure and Services

The road will have a **positive** effect of facilitating easier access for owner / operators and service providers, improving the local delivery of key services, such as healthcare, education, and community-based programs, potentially enhancing the availability and quality of these services for both current and new residents.

The road's development may have an indirect **positive** effect of reducing the logistical challenges and costs associated with transporting building materials and equipment, making it more cost-effective to service and expand local infrastructure. This could lead to faster development, including the expansion of essential infrastructure including power, water, wastewater, or education facilities.

9.5.6.4.4.2 Predicted Residual Effects

Methods of Transportation In and Out of the Community

Residual effects on transportation methods in and out of the community are expected to be **positive**.

Essential Infrastructure and Services

The residual effects on essential infrastructure and services are expected to be **positive,** given increased ease of access for service providers and reduced friction associated with infrastructure upgrades or improvements.

9.5.6.4.5 Housing

9.5.6.4.5.1 Potential Effects

Housing Suitability

The improved access from the Community Access Road may lead to a short-term, effect of decrease in housing suitability, as off-reserve residents and potential new residents choose to live in Marten Falls. This influx of new, permanent residents will put pressure on existing supply in Marten Falls which could disproportionately affect women, children, and Elders, particularly in overcrowded or substandard conditions. Women, especially those in single-parent households, may face added challenges managing limited space and resources.

Housing Adequacy

The Community Access Road will contribute to the **positive** effect of reduced costs and logistically challenges associated with building new homes and shipping materials to Marten Falls First Nation, improving the amount of adequate housing within the community.

Improved housing adequacy is expected to contribute to an indirect **positive** effect of improved health due to reduction in mold, poor ventilation, and overcrowding. This can lower the incidence of respiratory illnesses and other health problems often worsened by inadequate housing. The long-term benefits will include better mental health, particularly for women and children who are often the primary caregivers and spend the most time at home. Women, who are more likely to be responsible for maintaining the household environment, will experience improved health outcomes due to a healthier living space. Additionally, Elders, who may have more sensitive health conditions, will benefit from better air quality and safer living conditions.

Access to Building Materials for Housing

The Community Access Road will contribute to a **positive** effect of improving reliable access to construction materials and supplies, allowing more frequent repairs, upgrades, and construction of new homes. With continuous access to materials, repairs can be completed proactively, preventing them from escalating into larger issues. The availability of materials will help address long-standing housing needs within the community, improving living conditions for residents, particularly women, children, and Elders, who are more vulnerable to substandard housing.

While the Community Access Road will likely lower the cost and logistical barriers to transporting building materials, the community's existing infrastructure such as electricity, wastewater treatment, and access to clean drinking water, is already at capacity and would need upgrades to support future housing growth. To fully realize the benefits of improved transportation, an infrastructure review and planning process would be beneficial to identify and prioritize necessary upgrades. While responsibility for such planning falls outside the scope of the road project, Marten Falls First Nation may consider working with Indigenous Services Canada and other partners to explore opportunities for infrastructure investment and long-term community development.

There are no effects to housing anticipated for Aroland First Nation from the operations of the road as it is already road-connected year-long.

9.5.6.4.5.2 Mitigation and Enhancement Measures

Mitigation measures to meet changes in housing needs throughout operations include:

- Owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the Community Access Road, including topics associated with housing, such as tracking of housing demand and local infrastructure adjustments to meet changes in housing needs. This could include converting housing from the autonomous work camps as additional, permanent housing.

9.5.6.4.5.3 Predicted Residual Effects

There are no adverse residual effects associated with housing during operations.

There are no residual effects expected for Aroland First Nation for housing from the operations of the road.

9.5.6.4.6 Cultural Preservation and Change

9.5.6.4.6.1 Potential Effects

Traditional Economy

With the road in place, new harvesting areas may become accessible for Marten Falls First Nation and Aroland First Nation, which could have the **positive** of effect of renewing interest among youth and younger adults in participating in the Traditional Economy. Previously, access would have been limited to snowshoe, snowmobile, all-terrain vehicles, canoe, or boat, transportation options that require more time and potentially more safety concerns compared to using the new all-season road.

From a Gender-Based Analysis Plus perspective, the increased ability to easily access to hunting, fishing, trapping, and gathering areas is expected to have a **positive** effect, as it may encourage more youth and younger adults to engage in traditional activities. Easier access would reduce travel time to these locations, allowing community members to participate in traditional practices while balancing work or school commitments. For Elders and those with mobility challenges, the road provides an opportunity to reconnect with traditional activities like fishing, berry picking, and medicinal gathering, which may have been difficult to reach without this improved infrastructure.

Easier transportation of traditional foods may have a **positive** effect of creating new economic opportunities, such as selling fish, berries, and wild meats and other traditional goods, such as harvested berries, fish, and furs, to external markets. The road will also allow for increased trade or business partnerships between Marten Falls First Nation and Aroland First Nation, helping continue to build a strong relationship between the two communities.

The potential **positive** effects associated with the traditional economy may positively affect the road-connected Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake First Nation, Ginoogaming First Nation, and Long Lake #58 First Nation.

The potential **positive** effects associated with the traditional economy are not anticipated to affect the remote Indigenous communities with overlapping interests in the Local Study Area, including Neskantaga First Nation, Animbiigoo Zaagi'igan Anishinaabek, as they will not experience a change in accessibility.

Participation in Cultural Activities

The road will have a **positive** effect of increasing access for off-reserve members to attend cultural events such as pow wows, community feasts, and cultural weeks, in Marten Falls First Nation. Members of Marten Falls First Nation and Aroland First Nation expressed excitement that the road would increase their ability to attend traditional gatherings and pow wows in Marten Falls First Nation, noting that driving to the community would save a lot of money on flights. The road may encourage increased participation by Marten Falls First Nation members in activities in Aroland First Nation, as there will be a road connecting the communities. Nations collaborating to host and celebrate events may further strengthen the relationship between the communities, strengthening inter- and intra-community cohesion. Finally, improved access may increase participation in cultural education from off-reserve community members and make it easier for Elders and knowledge keepers that reside off-reserve to travel to the community strengthening intergenerational knowledge sharing. Younger community members may become more engaged and invested in learning and preserving cultural practices.

Use of Traditional Language

According to the 2021 Census, the percentage of Ojibway speakers in Marten Falls First Nation declined from 22 percent in 2016 to 18 percent. In contrast, the percentage of Ojibway speakers in Aroland First Nation increased from 35.6 percent in 2016 to 36.1 percent in 2021. With a lower population than Aroland First Nation, reasons for decreased traditional language use in Marten Falls First Nation may include out-migration, aging fluent speakers, fewer opportunities for language transmission, or Census data variability.

The road could increase interactions between Indigenous communities and traditional language users, particularly between Marten Falls First Nation and Aroland First Nation. This may lead to more opportunities for community members, particularly youth, to hear and practice the language and resulting in a **positive** effect of increased traditional language use.

9.5.6.4.6.2 Mitigation and Enhancement Measures

Participation in Cultural Activities

No mitigation measures are proposed.

Enhancement measures for participation in cultural activities include:

- Owner / operator to consider sponsoring community-driven cultural events that can take advantage of the improved access, incorporating local and regional participation. The road can help bring in off-reserve members, including those residing in Aroland, Municipality of Greenstone, Thunder Bay, and other communities, enriching the event experience without overshadowing the values of the community, and potentially strengthening the cultural values of both on- and off-reserve members. This could include festivals, gatherings, or knowledge-sharing initiatives that use the road as a tool for cultural exchange, and organization of traditional events like canoe races, fishing trips, or nature walks, that use the road as a tool to deepen the connection to the land and water.
- Owner / operator to consider sponsoring Elders and Indigenous Knowledge holders to travel to Marten Falls First Nation to provide cultural programming that may include workshops on teaching traditional skills related to hunting, trapping, traditional music, storytelling, or preparation of traditional foods.

Use of Traditional Language

Enhancement measures for language use include:

- Owner / operator or road owner to consider sponsoring Elders and knowledge holders that reside outside the community travel to community to teach the language to interested community members, through formal and informal settings.

9.5.6.4.6.3 Predicted Residual Effects

Traditional Economy

Residual effects for participation in the traditional economy are expected to be **positive**.

Participation in Cultural Activities

Residual effects for participation in cultural activities are anticipated to be **positive**.

Use of Traditional Language

Residual effects for change in use of traditional language is anticipated to be **positive**.

9.5.6.4.7 Community and Public Health

9.5.6.4.7.1 Potential Effects

Access to Health Services

The Community Access Road to Marten Falls First Nation is expected to have **positive** effects on access to health services due to reliable, year-round connection by an all-season road for both community members to access services only available in other regional centres and, for more reliable delivery of services in community.

Recreation

The Community Access Road to Marten Falls First Nation is expected to have **positive** effects on recreation, including youth sporting activities, cultural events, and other leisure activities, due to reliable, year-round connection by an all-season road for both community members to more easily engage in recreational activities outside the community and, to increase the planning and participation in recreational activities within the community year-round.

Mental Health and Well-being

The Community Access Road to Marten Falls First Nation is expected to have **positive** effects on mental health by improving access to care, reducing isolation, and enhancing opportunities for cultural and social engagement, including improved access to medical health services, faster response for mental health crises, reduced feelings of isolation, and improved effect on mental health and well-being.

The road will reduce logistical challenges in accessing mental health care, including counseling, addiction treatment, and crisis support services in regional centres such as Sioux Lookout and Thunder Bay. Currently, medical transportation for mental health services is limited by the availability of flights and the need for advanced planning. The road will allow for more timely access to appointments and emergency psychiatric care, reducing delays in treatment. The road will enable faster emergency interventions by allowing regional crisis teams paramedics, and police services to reach the community more efficiently, potentially preventing self-harm or overdose fatalities. Given the high rates of mental health service calls in the Nishnawbe Aski Police Service Central Region (404 calls related to mental health or suicide attempts in 2023-2024), reducing response times will be critical to community well-being.

Isolation has been a longstanding challenge in Marten Falls First Nation, contributing to mental health concerns such as depression, anxiety, suicide, and substance abuse. The road will allow community members to visit out-of-community family members,

participate in cultural events outside the community, and connect with external networks, without relying on expensive flights in and out of the community. This may increase social interaction and reduce feelings of disconnection.

The road removes transportation barriers to accessing mental health services, reducing emergency response times, potentially improving out-of-community social connections, and increasing participation in cultural practices, which contributes to overall improvements in mental health outcomes.

Although the road will enhance access to traditional lands and may support more frequent participation in land-based healing and cultural activities that have been identified as protective factors for mental health, there may also be effects due to the permanent, visual presence of the road contributing to feelings of disconnect and ecological grief. For some community members, the transformation of a familiar environment into a developed corridor may evoke sadness, anxiety, or a diminished sense of belonging, as the road may symbolize a disruption or fragmentation of relationships with the environment.

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming, and Long Lake #58 First Nations, face similar risks and potential negative effects to their mental health and well-being as those identified for Marten Falls First Nation and Aroland First Nation community members. Potential negative effects to mental health and well-being may be experienced due to permanent, visual changes to the land.

Substance Use

The Community Access Road to Marten Falls First Nation may have a effect on substance use within the community. A large percentage of the community (75 percent) is accessing substances despite current transportation limitations. The new all-season road access will reduce costs and logistical barriers for bringing all items, including alcohol and drugs, into the community. This could lead to increased frequency and / or quantity of use among existing users, given the reduced financial and logistical barriers.

While easier access to drugs and alcohol is a concern, the road may contribute to **positive** effects due to improved access to treatment options, providing a more balanced consideration of potential effects. With the road in operation, travel to treatment centres outside of the community and options to bring treatment programs and services to the community will become more affordable, reducing barriers for individuals seeking help for substance use. This could include day programs, counseling services, and follow-up support services, potentially improving long-term recovery outcomes. Service delivery, including access to withdrawal medications like

suboxone, is likely to improve. Community members have historically identified cultural activities as key to substance use prevention, emphasizing the importance of reconnecting with traditions and engaging in recreational, outdoor, and creative pursuits. Increased accessibility through the road can make it easier to access land-based programs while strengthening cultural ties.

It was identified that Marten Falls First Nation is working to build a community treatment centre in the community. The road will improve access to building materials and decrease transportation costs, making the construction of a community-based culturally relevant treatment centre feasible. This facility could integrate traditional healing methods with clinical care, providing a holistic and culturally appropriate recovery environment.

9.5.6.4.7.2 Mitigation and Enhancement Measures

Mental Health and Well-being

Owner / operator to form a Working Group with Marten Falls First Nation, Aroland First Nation, the owner / operator to co-develop a Safety and Wellness Plan that addresses project-related mental health and well-being concerns.

Substance Use

Owner / operator to form a Working Group with Marten Falls First Nation, Aroland First Nation, the owner / operator to co-develop a Safety and Wellness Plan that addresses project-related substance use concerns.

9.5.6.4.7.3 Predicted Residual Effects

Access to Health Services

Residual effects for access to health services are expected to be **positive**.

Recreation

Residual effects for recreation are expected to be **positive**.

Mental Health and Well-being

In general, mental health and well-being effects during operations are anticipated to be **positive** related to increased availability of mental health resources, treatment options, and decreased feelings of isolation. Increased access to care may lead to long-term improvements in mental health outcomes, reduce crisis incidents, reduce substance abuse and increase overall well-being. There is likely to be improvement in mental health resources, crisis response, and overall well-being, supported by evidence of

current service gaps and high crisis call rates, and local as primary benefits will occur within Marten Falls First Nation. This is likely to permanently improve access, reducing isolation and improving mental health outcomes over time, and this will occur on an ongoing basis once the road is operational.

However, mental health effects will not be experienced uniformly across the entire community, and here are **possible negative** residual effects related to a lost feeling of connectivity to land due to social and cultural sensitivities related to sense of place and identity. While the effect may be experienced by some individuals, it is not expected to affect the entire community uniformly and thus magnitude is **medium**. The effect is **local** because it is confined to the areas where construction will be occurring and may be **long-term** and **continuous** because it may persist as long as the road corridor exists. However, it may be **reversible** given increased access to mental-health supports and community and land-based activities. Uncertainty is **high**, because while feelings of ecological grief are relatively well-documented, the extent and intensity of this effect may vary individually.

Substance Use

There are **positive** residual effects expected with respect to substance use due to increased access to addictions treatment services and therapies, alongside increased mental health services.

However, a **possible negative** residual effect, even with mitigation, is the increased access to drugs and alcohol, which could lead to continued increases in substance use in the community. Especially given the increased access to mental health and addictions supports that the road connectivity will bring, the is **reversible** and uncertainty is **high**. Furthermore, increase in substance abuse is not expected to affect the community uniformly and thus magnitude is **medium**. The effect is **local, continuous** and **long-term** because the opportunity to access drugs and alcohol easily may persist as long as the road corridor exists.

9.5.6.4.8 Access to Clean Water

9.5.6.4.8.1 Potential Effects

Access to Clean Water

The Community Access Road will have a **positive** effect on the access to clean water as supply chain reliability will be improved, reducing disruptions in the delivery of essential resources, including clean water. Improved road access will also facilitate more frequent servicing and maintenance of the community's water treatment plant. With easier transportation for technicians, equipment, and materials, there is greater

potential for necessary upgrades and repairs to be completed efficiently. This increased capacity may help the facility reach and maintain operational standards, improving clean water access and reliability for residents.

Quality of Drinking Water

There is a potential for the quality of surface water and ground water to be negatively affected by the operations activities. A full assessment of the quality of surface water can be found in the Problem Formulation for Human Health Risk Assessment (Attachment A). Potential effects on human health may be affected from chemical exposures through the consumption of contaminated water or through dermal absorption (through the skin) during recreational activities, bathing, or other direct contact. Volatile substances in water may be inhaled during activities such as cooking and bathing. Operations activities that could affect quality of surface water include:

- Maintaining the Community Access Road, permanent access roads, bridges and culverts; and
- Operate the Community Access Road and permanent access roads.

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Attawapiskat, Kashechewan, and Fort Albany First Nations, face similar risks and potential negative effects to quality of surface water as those identified for Marten Falls First Nation and Aroland First Nation community members.

9.5.6.4.8.2 Mitigation and Enhancement Measures

Quality of Drinking Water

To mitigate negative effects on drinking and recreational water:

- Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Attawapiskat, Kashechewan, and Fort Albany First Nations, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including concerns related to contamination of ground and surface water.

9.5.6.4.8.3 Predicted Residual Effects

Access to Clean Water

Residual effects for access to clean water are expected to be **positive**.

Quality of Drinking Water

Residual changes to surface water quality are possible from the emission and deposition of airborne particulate matter to nearby waterbodies, sediment quality due to changes in land cover, changes in channel hydraulics at waterbody crossings, and wash off of accidental spills and leaks to nearby waterbodies. Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Attawapiskat, Kashechewan, and Fort Albany First Nations, face similar risks and potential negative effects to quality of surface water as those identified for Marten Falls First Nation and Aroland First Nation community members.

9.5.6.4.9 Traditional Foods

9.5.6.4.9.1 Potential Effects

The impact of the Community Access Road on traditional foods are explored further in the Aboriginal Treaty Rights and Interests assessment.

Access to Traditional Foods

The operation of the Community Access Road will have a **positive** effect on the accessibility of traditional foods. Key harvesting sites will be more accessible by the all-season road, making it easier for community members to participate in traditional activities such as hunting, trapping, fishing, and plant gathering. Elders and youth, who may currently face challenges reaching traditional lands due to distance or winter road conditions, could find it easier to participate, supporting intergenerational knowledge transfer. Aroland First Nation may benefit from greater access to traditional fishing and berry harvesting sites with the road providing more consistent access to key fishing areas along the Albany River, including Ogoki Falls and Amy Falls, supporting traditional fishing practices. Easier transportation of harvested fish and berries may encourage greater community participation in food-sharing networks. The Aroland Youth Blueberry Initiative could benefit from improved transportation, allowing more youth to participate in harvesting and selling blueberries. Increased access to markets may enhance economic opportunities for community-led food security programs.

The potential **positive** effects associated with the increased accessibility of traditional foods may be experienced by the following road-connected Indigenous communities with overlapping interests in the Local Study Area including Constance Lake First Nation, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming First Nation, and Long Lake #58 First Nation.

However, the following remote Indigenous communities with overlapping interests in the Local Study Area are not expected to experience any change: Fort Albany First Nation, Attawapiskat First Nation, Kasabonika Lake First Nation, Kitchenuhmaykoosib Inninuwug First Nation, Kingfisher Lake First Nation, Neskantaga First Nation, Nibinamik First Nation, Wapekeka First Nation, Wawakapewin First Nation, Webequie First Nation, Weenusk First Nation, and Wunnumin Lake First Nation.

Availability of Traditional Foods

The operation of the Community Access Road will have an effect on the availability of traditional foods The road will open access to new areas for the general public, increasing access to hunters and fishermen to areas that were previously not easily accessible. Easier, year-round access may lead to a reduction in availability of traditional foods, due to over-harvesting and environmental strain. There may be increased pressure on fish populations on the Albany River, moose hunting, and on berry harvests, supporting the need for sustainable management practices. Members of Marten Falls First Nation have expressed concerns about increased access as higher numbers of outsiders hunting and fishing, which may reduce the availability of traditional hunting grounds (Three Roads Forum, personal communication, Feb 27, 2025).

Road access may increase hunting pressure on game and traditional foods, particularly caribou, which is valued by Aroland First Nation. While caribou hunting is prohibited for the general public in Ontario, Indigenous hunters from outside the region and poachers may contribute to increased harvest. Hunting of birds and other game by the general public could further reduce the availability of traditional foods. There is concern that additional pressure on caribou could lead to a reduction in availability or their disappearance from the region. Road access may also increase hunting pressure on moose, which is valued by Marten Falls First Nation and Aroland First Nation. Increased access to previously remote areas along the Community Access Road may facilitate an increase in access by the general public.

The potential **negative** effects associated with the availability of traditional foods may also be experienced by the regional communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming, and Long Lake #58 First Nations.

Reliance on Store-Bought Foods

The operation of the Community Access Road will have a positive effect on the reliance on store-bought foods. Road transportation is expected to reduce the cost of groceries by lowering shipping costs, making store-bought food more affordable for community members. With fewer transportation delays and a more reliable supply chain, perishable

foods such as fruits, vegetables, dairy, and meats will arrive fresher and in better condition, reducing consumption of near-expired or lower-quality goods. Fewer delays due to flight schedules and weather disruptions could enhance food security and reduce food waste. Access to fresher, higher-quality foods could support improved nutrition and health outcomes, particularly if paired with nutrition education initiatives promoting health food choices.

Aroland First Nation is already road accessible, but there is potential with increased store-bought food shipments to Marten Falls First Nation, that Aroland First Nation may also see increased shipments and supply-chain reliability along the delivery route, which could increase reliance on store-bought foods.

Quality of Traditional Foods

A full assessment of the potential effects to the Quality of Traditional Foods is included in the Problem Formulation for Human Health Risk Assessment (Appendix T). Potential effects that could arise through contaminant releases during operations and their potential to affect the environment influencing human health could result in changes to the Quality of Traditional Foods. The quality of traditional or country foods is closely linked to the health of the surrounding environment. For instance, fish thrive in clean, unpolluted waters, and their health directly affects the safety and nutritional value of the fish consumed. Similarly, berries and other wild fruits depend on clean air and soil to grow robustly, free from harmful contaminants. Wildlife, a common source of traditional meats, requires a healthy and suitable habitat to flourish; polluted environments can lead to diseases and reduced populations. Residual effects of road Operations in surface water, groundwater, air, soils, peatlands, and noise-induced stress can cause contamination to the local and regional environment. When country foods are harvested from contaminated environments, the contaminants can pose a direct risk to those who consume them.

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake First Nation, Fort Albany First Nation, Attawapiskat First Nation, Kashechewan First Nation, Kasabonika Lake First Nation, Kitchenuhmaykoosib Inninuwug First Nation, Kingfisher Lake First Nation, Eabametoong First Nation, Mishkeegogamang First Nation, Neskantaga First Nation, Nibinamik First Nation, Wapekeka First Nation, Wawakapewin First Nation, Webequie First Nation, Weenusk First Nation, Wunnumin Lake First Nation, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming First Nation, and Long Lake #58 First Nation, face similar potential negative effects related to the quality and availability of traditional foods as those identified for Marten Falls First Nation and Aroland First Nation.

9.5.6.4.9.2 Mitigation and Enhancement Measures

Mitigation measures for the consumption of traditional foods:

- Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including discussions about pathways to contamination through traditional foods and opportunities to prevent contamination for example signage related to washing dust off gathered foods.
- Further discussion during detail design between the owner / operator, the project owner to work with Ontario's Ministry of Natural Resources to encourage more frequent patrols of Conservation Officers along the Community Access Road to confirm hunters and fishermen are not exceeding their limits and that they have the proper tags and licenses.
- Owner / operator to work with communities and governments, as required, to support education and development of Indigenous Conservation Officer (Game Warden) program.
- Owner / operator to sponsor community-led harvesting initiatives in Marten Falls First Nation and Aroland First Nation.

Enhancement measures for the consumption of traditional foods:

- Owner / operator to consider sourcing traditional foods for the work camps, where it is possible, to support local harvesters and small businesses.

9.5.6.4.9.3 Predicted Residual Effects

Access to Traditional Foods

Positive residual effects on traditional foods include long-term improved access to harvesting areas, stronger support for traditional food programs and youth initiatives, improving local food security and Indigenous Knowledge transmission.

Availability of Traditional Foods

Possible negative residual effects on availability traditional foods include a **local** decrease in availability of traditional food resources, due to disruption from the road itself or the result of increased harvesting due to increased access. While this effect may be of **moderate** magnitude, **local** and **long-term**. This effect may be **infrequent and reversible, and has a high** uncertainty.

Reliance on Store-Bought Foods

Positive effect of increased access to store-bought foods as a result of reduced costs due to less-expensive road transport.

Quality of Traditional Foods

The quality of fish, vegetation, wildlife, birds, and ungulates as a traditional food is dependent on the quality of their habitat or namely the surface water, air and soil quality to which they are exposed. Effects from soil contamination leaching, emissions of criteria air contaminants and deposition to surface water, changes to erosion and sedimentation, changes to surface water quality, dust deposition, and increased public access to fish have the potential to affect the quality of fish, vegetation, wildlife, birds, and ungulates as country foods and potentially affect human health.

These negative residual effects on the availability and quality of traditional foods apply to the Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake First Nation, Fort Albany First Nation, Attawapiskat First Nation, Kashechewan First Nation, Kasabonika Lake First Nation, Kitchenuhmaykoosib Inninuwug First Nation, Kingfisher Lake First Nation, Eabametoong First Nation, Mishkeegogamang First Nation, Neskantaga First Nation, Nibinamik First Nation, Wapekeka First Nation, Wawakapewin First Nation, Webequie First Nation, Weenusk First Nation, Wunnumin Lake First Nation, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming First Nation, and Long Lake #58 First Nation, face similar potential negative effects related to the quality and availability of traditional foods as those identified for Marten Falls First Nation and Aroland First Nation.

9.5.6.4.10 Public Safety

9.5.6.4.10.1 Potential Effects

The operations the Community Access Road to Marten Falls First Nation is expected to influence public safety, including licenced driving, road safety, access to emergency services and experiences of violence and harassment.

Driver's Licence

During operations, there is potential for increased employment opportunities. As during construction, a valid driver's license will help enable Marten Falls First Nation and Aroland First Nation residents to access direct and indirect jobs related to the operations of the Community Access Road, such as equipment operation, truck driving, delivery services, and potentially community shuttles. The lack of a driver's license may limit access to training programs related to direct or indirect jobs related to the

operations of the Community Access Road, as some training programs may require a valid driver's license as a prerequisite. This could limit the ability of residents to qualify for certain roles during operations, potentially effecting their opportunities to take full advantage of training and employment opportunities.

The absence of a driver's license, due to barriers to successfully completing a driver's licence assessment or difficulties accessing required documentation, could limit community member's ability to gain the necessary qualifications for employment opportunities, ultimately restricting the benefits of the project to the community. Unless barriers are addressed, there is likely to be the negative effect that demand for workers with Driver's licences exceeds those available, thereby limiting the community benefits of the Project.

Road Safety

During the operations phase, the Community Access Road is expected to have higher traffic volumes compared to the winter road and therefore likely an effect on road safety due to increased number of road-related injuries and accidents.

It is important to distinguish that, on a per-kilometre basis, the Community Access Road is expected to provide safer and more predictable driving conditions, reducing risks associated with weak ice, poor construction, and inadequate signage. The Community Access Road will be built to mandatory technical and safety standards, unlike the winter road, which follows voluntary guidelines. The new road will offer consistent safety standards year-round, unlike the winter road, where conditions fluctuate daily. While these improved road conditions may reduce the risk per vehicle, the overall number of accidents is likely to increase due to the higher number of vehicles / increased frequency of trips. As a result, the existing road near Aroland First Nation may also see a higher frequency of collisions and traffic-related incidents. Furthermore, the barriers to obtaining driver's licenses and vehicle registration may continue to be an issue for some Marten Falls First Nation and Aroland First Nation residents. Without these, drivers may be at higher risk for accidents and non-compliance with the Highway Traffic Act.

Additionally, the perceived reliability of the Community Access Road may encourage higher speeds and may lead to overconfidence in dangerous conditions (for example, driving in poor weather without proper precautions) potentially increasing opportunities for accidents and more high-speed collisions. Easier access to drugs and alcohol may also contribute to increased driving incidents. Clear signage and speed limits, as well as consistent enforcement of traffic laws will help mitigate dangerous driving behaviours, reduce total number of accidents, and support road safety.

The effect on road safety due to increased number of road-related injuries and accidents may also be experienced outside the Local Study Area, by regional municipal communities of Thunder Bay and Greenstone.

Access to Emergency Services

The Community Access Road is expected to have a **positive** effect on access to emergency services as it will allow for quicker emergency response by police, fire and medical services for road-related accidents and community emergencies in the Local Study Area. The road will also facilitate better coordination of regional resources and equipment for natural disasters such as wildfires and floods, while reducing reliance on air transport. Although Marten Falls First Nation does have local emergency responders, regional responders will be able to access the community more quickly to address issues.

Access to medical transportation by road will reduce reliance on air transport, which can be delayed due to weather conditions or higher-priority patients elsewhere in the region. Faster access to out-of-community hospitals could lower mortality rates and prevent complications from delayed care. Residents will have the option to drive themselves to medical centres, improving access to both urgent and routine healthcare. Women may have more flexibility in accessing prenatal care and may be able to stay in the community longer before relocating to give birth. Provincial policies, known as forced birth evacuations, may still require expectant mothers to leave weeks in advance (National Council of Indigenous Midwives, 2020). The road may improve comfort and reduce travel costs, though, it will not change the requirement for expecting mothers to leave their communities to give birth.

Violence and Harassment

The Community Access Road may influence violence crime dynamics the Local Study Area by increasing accessibility to and from the communities. While improved policing response times could help address violent incidents more effectively, increased road access to Marten Falls First Nation may also contribute to new safety concerns.

There is potential for road access to lead to an influx of drugs, alcohol, and other external influences that could contribute to higher crime rates, including assaults and property-related offenses. Increased mobility may also heighten risks of human trafficking, particularly for Indigenous women and gender-diverse individuals, who are already disproportionately affected by trafficking. This combined with the lack of cell service in the corridor surrounding the road, could pose additional risk for people travelling the road, especially women and girls. Through the Indigenous Knowledge Program, Aroland First Nation have noted that the Community Access Road will increase access to the area from outsiders, potentially jeopardizing the safety of their community members.

The increased movement of people and external influences may intensify existing social tensions, contributing to lateral violence, including bullying, exclusion, and intimidation. Greater exposure to outside perspectives and economic disparities could heighten divisions within the community, particularly if access to new opportunities is not equitably distributed. Increased interaction with non-community members may also lead to shifts in social dynamics, potentially reinforcing existing power imbalances or conflicts related to governance, employment, and resource access.

With year-round road access, emergency responders, peace officers and support workers can respond more quickly to violent crimes, domestic disputes, and other emergencies requiring additional personnel. Easier transportation for social services, crisis intervention teams, and mental health supports may provide more timely assistance to victims of violence and harassment. Increased connectivity may allow for greater collaboration between Marten Falls First Nation, law enforcement, and social agencies to implement community-led safety programs.

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming, and Long Lake #58 First Nations, face similar risks and potential negative effects related to crime, violence, and safety. This is also possible for regional municipal communities including Thunder Bay and Greenstone. Potential effects include increase in violence and criminal activity, particularly human trafficking.

9.5.6.4.10.2 Mitigation and Enhancement Measures

Drivers Licence

To address the barriers to obtaining a driver's licence in Marten Falls First Nation, the following mitigation measures should continue from construction into operations to support community goals of public safety:

- Owner / operator of the road to explore or continue to support opportunities to increase total Driver Licence holders, alongside the Ministry of Transportation, partnering with organizations such as:
- Kiikenomaga Kikenjigewen Employment and Training Services, or other trusted organizations, to offer driving training programs to support community members in passing their assessments;
- Third-party organizations that provide drivers licence testing for remote communities.

Road-related Injuries and Safety Standards

Mitigation measures for road-related injuries and safety standards include:

- The owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the road safety during operation of the Community Access Road, such as traffic challenges, emergency preparedness plans, and safe driving campaigns;
- The road owner will need to engage with law enforcement to implement increased monitoring; prepared for the opening of the road, allowing for an increased presence to monitor traffic, enforce speed limits, and deter impaired or reckless driving;
- The owner to consider alternative methods to using salt on roads to prevent attracting wildlife, minimizing the potential for vehicle-wildlife collisions; and
- The owner to consider the installation of road signage in both English and traditional languages indicated speed limits, sharp turns, wildlife crossings, and other hazards.

Enhancement measures for road-related injuries and safety standards includes:

- The project owner should consider launching public awareness campaigns to educate Marten Falls First Nation members on safe driving practices, the benefits of the new road, and responsible road use.

One mitigation measure heard from the community- installing a gate to block outsiders from accessing the area – would be difficult to implement for practical and safety challenges. If the road ownership is public, a private gate cannot be installed on a public road preventing access. A logistical concern is the need for personnel stationed at the gate 24-hours a day to allow community members to freely travel in and out of the community. Even if members were given a key to use the gate, there are safety implications if someone forgot their key and did not have enough gas to turn around to get to Aroland First Nation or to cell service. For these practical and safety-related reasons, this mitigation is not being proposed at this time.

Marten Falls First Nation continues to engage in discussions with the Province regarding the ownership and future operations of the Community Access Road. Access and ownership including gating security / ID system, will require further dialogue between the communities and the Province.

Violence and Harassment

Mitigation measures related to violence and harassment include:

- The owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation, and other interested Indigenous and municipal communities, to meet regularly to discuss community-proposed topics in relation to the operations of the Community Access Road, could include the consideration of developing community-based violence prevention programs, including safe shelters and crisis support for victims; strengthening mental health, addictions, harm reduction programs, and family support services to address root causes.

9.5.6.4.10.3 Predicted Residual Effects

Road Safety

Despite the implementation of mitigation measures, some **probable negative** residual effects on **local** road safety may persist at a **moderate** magnitude with **low** uncertainty. It is anticipated this residual effect will be **infrequent**, but **continuous** and **irreversible**. These negative residual effects on road safety due to increased number of road-related injuries and accidents may also be experienced outside the Loca Study Area, by regional municipal communities of Thunder Bay and Greenstone, even though the risk per vehicle may decrease due to overall improved all-reason road conditions.

Violence and Harassment

Even with the mitigation measure, there is still the potential for a **possible negative** residual effect associated with an increase in human trafficking and criminal activity and family and social conflicts, which may continue as economic and social shifts occur **locally**. This residual effect is anticipated to be of **moderate** magnitude with **low** uncertainty while being **infrequent** and **continuous** but **reversible.**

Indigenous communities with overlapping interests in the Local Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming, and Long Lake #58 First Nations, face similar risks and potential negative residual effects related to crime, violence, and safety. These residual effects are also possible for regional municipal communities including Thunder Bay and Greenstone. Potential residual effects include increase in violence and criminal activity, particularly human trafficking.

9.5.6.4.11 Biophysical Determinants to Human Health Effects

9.5.6.4.11.1 Potential Effects

The biophysical factors potential influencing human health during operations are similar to those during construction. In some instances, reduced activity during operations may lessen the potential effects, while in other cases, certain activities may increase, amplifying the potential effects. A summary of contaminant release during construction and their potential to affect the environment influencing human health has been included for each biophysical indicator.

For the purpose of this assessment, changes to the quality of the environment where country foods are harvested, as described above, will be used to evaluate the potential residual effects associated with project-related activities that may affect the quality of these foods. Biophysical determinants to human health may be affected by chemical exposures through the consumption of contaminated country foods, depending on the type, magnitude, and frequency of exposure. Further information on potential effects is included in the Problem Formulation for Human Health Risk Assessment in Appendix T.

Air Quality

A summary of contaminant releases during operations and their potential to affect the environment influencing human health include:

- Emissions of volatile substances (in other words, burning of fossil fuels in vehicles and equipment)
- Elevated concentrations of particulate matter resulting from fugitive road dust.

Noise and Vibration

As the magnitude of the residual effects from the increased noise due to road operations is low, and the residual effects from the increased noise due to quarry use are not predicted to be frequent, the noise and vibrations technical support team determined residual effects during operations are assessed as not significant.

Because the residual effects from the increased vibration during construction and operations are not predicted to be long-term in duration or frequent, the noise and vibrations technical support team determined residual effects during are assessed as not significant.

Soil Quality

A summary of contaminant releases during operations and their potential to affect the biophysical environment for soil quality influencing human health include:

- Potential effects on human health may occur through incidental ingestion of soils on country foods, inhalation of dust, or dermal absorption (through the skin). Operations activities that may affect soil quality include:
  - Leaks and spills during equipment, supplies and personnel mobilization; and
  - Deposition of dust from blasting and mobilization activities.

Soil quality may be adversely affected by hazardous material leaks, spills, or deposition of air emissions and dust during operation. Existing soil analysis shows some concentrations exceeding applicable standards, and any residual effects could compound these exceedances. Predicted soil concentrations have not been modeled. Effects on soil quality during operations are predicted to be short-term and limited to the Construction Disturbance Area.

Sediment Quality

A summary of contaminant releases during operations and their potential to affect the biophysical environment for sediment quality influencing human health include:

- Potential effects on human health may be affected by chemical exposures through the consumption of contaminated water or through dermal absorption (through the skin) during recreational activities, bathing, or other direct contact. Both surface water and groundwater have the potential to be used as potable water sources and could be used for cooking and bathing. Operations activities which may affect sediment quality include:
  - Maintaining the Community Access Road, permanent access roads, bridges and culverts; and
  - Operate the Community Access Road and permanent access roads

Land Use

A summary of contaminant releases during operations and their potential to affect the biophysical environment for land use influencing human health include:

- Human health may be affected from chemical exposures through the inhalation of contaminated air, consumption of contaminated water or through dermal absorption (through the skin) during recreational activities, bathing, or other direct contact with contaminated water, soils or sediment. Volatile substances in water

may be inhaled during activities such as bathing and cooking. Construction activities that may affect Human health include:

- Maintaining the Community Access Road, permanent access roads, bridges and culverts; and
- Operate the Community Access Road and permanent access roads.

Peatlands

A summary of contaminant releases during construction and their potential to affect the environment for peatlands influencing human health include:

- Within the Local Study Area, peatlands are existing sources of carbon dioxide and methane. Construction activities will remove portions of the wetland, reducing the amount of carbon dioxide and methane released by natural processes, having a positive effect over the long-term. Peatlands Technical Support Document [Appendix I].

Accidents and Malfunctions

A summary of contaminant releases during operations and their potential to affect the biophysical environment for accidents and malfunctions influencing human health include:

- Accidents and malfunctions can affect the quality of soils, sediment, surface water and groundwater, and therefore Country Foods. Potential effects on human health may be through chemical exposures through the consumption of contaminated water or through dermal absorption (through the skin) during recreational activities, bathing, or other direct contact. Operations activities which may affect soil, sediment, surface water and groundwater quality include:
  - Maintaining the Community Access Road, permanent access roads, bridges and culverts;
  - Operations of the Community Access Road is expected to result in increased dust generation in comparison to construction.

9.5.6.4.11.2 Mitigation and Enhancement Measures

In general, mitigations during operations include:

- Obtaining all required permits, authorizations, and approvals prior to conducting specific maintenance activities;
- Complying with all applicable regulations, legislation, permit requirements, and best practices regarding all work;

- Development and compliance with Project specific Management and monitoring plans. Examples include a Construction Best Management Practice Plan, Blasting and Communication Management Plan, Erosion and Sediment Control Plan, Fugitive Dust Management Plan;
- Timing maintenance activities to minimize environmental effects;
- Owner / operator to develop a community-based reporting system that enables community members and employees to report concerns, including those related to the biophysical environment;
- During detail design, complete an existing conditions assessment including laboratory analysis of the quality of the water from the Albany River being used as drinking water. During construction, a regular monitoring / sampling program will be conducted until the boil-water advisory is lifted;
- During detail design, conduct an existing conditions assessment including laboratory analysis of traditional foods; and
- The owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area—including Constance Lake First Nation, Fort Albany First Nation, Attawapiskat First Nation, Kashechewan First Nation, Kasabonika Lake First Nation, Kitchenuhmaykoosib Inninuwug First Nation, Kingfisher Lake First Nation, Eabametoong First Nation, Mishkeegogamang First Nation, Neskantaga First Nation, Nibinamik First Nation, Wapekeka First Nation, Wawakapewin First Nation, Webequie First Nation, Weenusk First Nation, Wunnumin Lake First Nation, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming First Nation, and Long Lake #58 First Nation—to meet regularly to discuss community-proposed topics in relation to the operations of the Community Access Road, including concerns related to the biophysical effects on human health during construction, such as air, noise and vibration, sediment, soil, ground and surface water, and land-use.

9.5.6.4.11.3 Predicted Residual Effects

Determining the magnitude and extent of residual effects of project construction activities on biophysical human health requires the modelling of predicted concentrations based on expected Project activities. For this project, air concentrations during operations were the only aspect modelled as part of the technical study. High magnitude effects were predicted for the air quality contaminants in **Table 9.5-32**.

Table 9.5-32: Air Quality Contaminant Modelling

Parameter	Duration	Location	Extent (Community Access Road)
Particulate Matter Less than 2.5 Micrometres	24-hour	North-south road segment	115 metres from road
Particulate Matter Less than 2.5 Micrometres	Annual	North-south road segment	134 metres from road
Particulate Matter Less than 10 Micrometres	24-hour	North-south road segment	1,986 metres from road
Particulate Matter Less than 10 Micrometres	24-hour	Community road segment	50 metres from road
Total Suspended Particulate	24-hour	North-south road segment	3,004 metres from road
Total Suspended Particulate	24-hour	Community Access Road segment	119 metres from road
Total Suspended Particulate	Annual	North-south road segment	899 metres from road
Dust deposition	30-day	North-south road segment	45 metres from road
Dust Deposition	annual	North-south road segment	681 metres from road
Dust Deposition	annual	Community Access Road segment	28 metres from road

Source: Atmospheric Environment Technical Support Document - Volume 1: Air Quality (**Appendix S**).

Residual effects to surface water, groundwater, soils, and sediment, including deposition of dust onto surface water soils and sediment, were not evaluated in the individual technical studies.

9.5.6.4.11.4 Predicted Indirect Effects

Indirect effects on biophysical human health are anticipated to result from changes in land use. These changes may influence the quantity and variety of traditional foods consumed, the locations of exposure to soils, sediment, surface water and air, and the durations of exposures. These factors could contribute to an increased potential for unacceptable risks to human health.

9.5.6.5 Summary of Residual Effects

Table 9.5-33 provides a summary of the potential effects for community well-being, mitigation measures, and residual effects. Detailed information is included in **Appendix T**.

Table 9.5-33: Summary of Residual Effects for Community Well-being Discipline and Characterization

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Sustainable Population Growth**	• Construction	• Negative effect to community cohesion due to rapid changes in the on-reserve population in age and gender distribution as well as overall community population	• The owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation to discuss community concerns and proposed topics, including those in relation to changes in population or social demographics. • Owner / operator to implement Diversity, Equity, and Inclusion hiring policies to prioritize women and reduce gender disparities. • Owner / operator to house workers in autonomous camps to limit demographic shifts and disruptions in community.	• No residual effect anticipated.	• No residual effect anticipated.
• **Sustainable Population Growth**	• Operations	• Positive effect of shift towards a balanced age distribution due to reduced out-migration among younger families, improved Elder retention; easier travel for employment, education, and services.	• Owner / operator to house workers in autonomous camps to limit demographic shifts and disruptions.	• No residual effect anticipated.	• No residual effect anticipated.
• **Sustainable Population Growth**	• Operations	• Positive effect of increasing community population due to attraction of off-reserve members and external workers.	• No mitigation measures proposed.	• No residual effect anticipated.	• No residual effect anticipated.
• **Labour Market Dynamics**	• Construction	• Negative effect of a short-fall in local labour availability compared to demand for employment.	• The owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation to discuss construction-related issues and unemployment by identifying and removing employment barriers, offering job readiness programs, and providing counseling and addiction support services to support community members. • Owner / operator to implement Community Readiness Strategies and Adaptive Management Plans to assess and respond to community needs. • Owner / operator to provide information on available opportunities to help community members obtain necessary qualifications. • Owner / operator to create a Local Training Plan to complete a local skills assessment and utilize local labour force. • Owner / operator to offer ongoing job readiness programs and coordinate training timing to support workforce transition and career growth. • Owner / operator to implement Diversity, Equity, and Inclusion hiring policy, enhanced through training programs, job fairs, and outreach, to actively prioritize women in construction-related employment opportunities and reduce gender disparities in the work force. • Owner / operator to gradually integrate new workers into the workforce through shorter days and shift rotations. • All construction workers to be housed in autonomous work camps to limit disruptions to communities.	• No residual effect anticipated.	• No residual effect anticipated.
• **Labour Market Dynamics**	• Construction	• Positive effect of the creation of direct, indirect, and induced jobs • Positive effect of increased labour income and Gross Domestic Product contributions.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Labour Market Dynamics**	• Operations	• Positive effect of the creation of direct, indirect, and induced jobs • Positive effect of increased labour income and Gross Domestic Product contributions.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Labour Market Dynamics**	• Operations	• Positive effect on educational attainment.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Construction	• Positive new business opportunities for Indigenous businesses related to construction contracts and services.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Construction	• Negative disruptions to local businesses during construction.	• Owner / operator to implement Community Readiness Strategies and Adaptive Management Plans to assess and respond to community needs. • Owner / operator to create a Local Content Plan to utilize a certain dollar value or share towards local businesses and owner / operators. • Owner / operator to consult with local businesses that would be potentially affected by work zone effects and determine the optimal times and conditions for the construction to take place, such as during off-peak times.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Operations	• Negative effect of ongoing opportunities for Indigenous businesses in road operation and maintenance and transportation services.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Construction	• Positive effect of significant tax revenue generation.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Operations	• Positive effect of total tax revenue effect of $2.7 million in Ontario and $3.0 million in Canada.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Construction	• Positive impact effect on Gross Domestic Product, labour income, gross operating surplus, and tax revenues.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Operations	• Total economic activity of $22.4 million in Ontario and $24.8 million in Canada. • Positive effect on Gross Domestic Product, labour income, and gross operating surplus, and tax revenues.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Construction • Operations	• Positive effect on the productivity of individuals and businesses in the region.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Construction • Operations	• Positive effect on the value of land that is surrounding the transportation infrastructure.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Economy**	• Construction • Operations	• Positive effect on diversifying the economy.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Community Access to Infrastructure and Services**	• Construction	• Negative effect due to increased transportation to and from the community.	• Owner / operator will develop an Equipment Mobilization Plan with both Marten Falls First Nation and Aroland First Nation for the movement of equipment, personnel, supplies, and resources. Where possible, construction traffic should be separated from community traffic to improve safety and minimize disruptions. The mobilization plan should also include a clear communications strategy to keep the community informed of the mobilization schedule, making residents aware of periods of increased heavy equipment traffic on the winter road. • Owner / operator, when possible, will transport employees on a charter flight.	• Residual changes to Community Access to Infrastructure and Services due to increased transportation to and from the community.	• Context: Possible increase in access to community via winter road / air • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: Low • Significance: Not Significant • Confidence: High
• **Community Access to Infrastructure and Services**	• Construction	• Negative effects due to increased pressure on local infrastructure and essential services.	• Owner / operator will establish working groups with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including topics avoiding pressure on local, essential services and infrastructure. • All construction workers (including on- and off-reserve members) will be housed in autonomous work camps equipped with independent water, wastewater, and power systems. These systems need to be properly maintained to reduce reliance on community infrastructure and to prevent contamination risks. • Owner / operator will develop waste management policies to minimize waste production and support responsible disposal. Collaboration with the community will be prioritized to develop effective construction waste management and disposal strategies, incorporating local input. • Owner / operator will establish a secure fuel storage facility and maintain a reliable fuel supply throughout the construction season. Fuel deliveries will be planned in advance and transported via the winter road, reducing reliance on costly air transport and preserving community fuel resources. All fuel storage sites will comply with safety and environmental regulations to prevent spills and contamination.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community Access to Infrastructure and Services**	• Operations	• Positive effects due to increased year-round access to and from the community.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community Access to Infrastructure and Services**	• Operations	• Indirect positive effect due to increased access to goods and services (including reduced costs).	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community Access to Infrastructure and Services**	• Operations	• Positive effects due to increased delivery of essential services in community.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community Access to Infrastructure and Services**	• Operations	• Indirect positive effect due to reduced costs and logistical challenges to building and maintaining essential infrastructure.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Housing**	• Construction	• Negative effect due to increased demand for housing, potential overcrowding.	• Owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including topics associated with housing adequacy and converting construction camps to permanent housing. • House workers in autonomous camps to limit demographic shifts and reduce pressure on community housing.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Housing**	• Operations	• Negative effect on housing suitability due to increased demand for housing, potential overcrowding.	• Owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the Community Access Road, including topics associated with housing, such as monitoring of housing demand and adjustments to meet changes in housing needs.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Housing**	• Operations	• Positive effect on housing adequacy due to reduced transportation costs and logistical challenges to building new homes.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Housing**	• Operations	• Indirect positive effect on health due to improved housing adequacy for example reduced mold / overcrowding.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Housing**	• Operations	• Positive effect of improved accessibility of building materials.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Cultural Preservation and Change**	• Construction	• Negative effect due to disruption to traditional economy and cultural practices.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including where to appropriately locate safety pull out areas to promote access, and other traditional harvesting issues. • Prior to construction, owner / operator will develop Access Management Plans with Marten Falls First Nation and Aroland First Nation in relation to hunting, trapping and gathering activities. All activities must conform to licensing requirements and adhere to the rules and regulations under the Ministry of Natural Resources. • Provide flexible work schedules during key hunting, trapping, and gathering seasons to support continued access to traditional food sources. • Owner / operator to sponsor community-led harvesting initiatives.	• Residual changes to Cultural Preservation and Change due to disruption to traditional economy and cultural practices	• Context: Possible shift from traditional economy activities • Direction: Negative • Magnitude: Low • Geographic Extent: Construction Disturbance Area • Duration: Medium-term • Frequency: Frequent • Reversibility: Irreversible • Likelihood: Possible • Uncertainty: High • Significance: Not Significant • Confidence: Moderate
• **Cultural Preservation and Change**	• Construction	• Negative effect due to traditional language decline.	• Owner / operator to provide Training and Work Materials in Indigenous Languages. Offer onboarding materials, safety protocols, and job-related paperwork in Indigenous languages alongside English to provide language accessibility for all workers. • Owner / operator to implement multi-lingual worksite signage. Reduce language barriers at the worksite by using multi-lingual signage at work sites, including directional signs, safety notices, workplace policies, and equipment labels, to promote the use of Indigenous languages in the workplace. • Owner / operator to provide Cultural Sensitivity and Language Awareness Training. Educate non-Indigenous supervisors and workers on the importance of Indigenous languages in cultural identity, knowledge transmission, and community well-being. Encourage an inclusive workplace where traditional language use is supported and valued.	• No adverse residual effect anticipated.	• No residual effect anticipated.

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
			• Owner / operator to implement a Zero-Tolerance Policy for Language Discrimination. Establish clear workplace policies so that Indigenous workers are not discouraged from speaking their traditional language. Supervisors and project managers should actively reinforce language inclusivity and address any instances of discrimination or bias. • Owner / operator to introduce a cultural safety mechanism. Introduce a workplace mechanism, such as a cultural safety flag, allowing employees to pause work or request support if they feel uncomfortable due to language-related issues. Propose a Cultural Safety and Stop Work Protocol.		
• **Cultural Preservation and Change**	• Operations	• Positive effects on traditional economy; enhanced participation in cultural activities; increase in traditional language due to increased access and connection for community members.	• No mitigation measures proposed	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community and Public Health**	• Construction	• Positive effect of improved mental well-being through employment in construction, increased financial stability, and greater self-sufficiency, which can reduce financial stress, and improve sense of pride and confidence.	• No mitigation measures proposed	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community and Public Health**	• Construction	• Negative effect on mental health and well-being due to long hours, tight deadlines, and physically demanding tasks, leading to stress and fatigue; potential for social disconnection and emotional strain from extended periods away from families; employment disparities; and sensory disturbances and restricted land access.	• Owner / operator to collaborate with Marten Falls First Nation and Aroland First Nation to provide mental health counseling, mentorship, and peer support at work camps, with onsite Elders or cultural liaisons to promote emotional and cultural well-being, support skill development and workplace adjustment. • Owner / operator to implement a gradual work force integration for community members, introducing shorter workdays and shift rotations (for example, starting with 2-3 days on with a day or two break instead of 10 consecutive days) to ease new workers into construction roles. • Owner / operator to provide cultural safety training for all workers, including supervisors and non-Indigenous employees, to complete training on Indigenous culture, traditions, and historical experiences, to promote a safe and inclusive work environment. • Owner / operator to hold training session on violence and harassment prevention. • Owner / operator to enforce a zero-tolerance policy for workplace discrimination so that Indigenous workers feel respected and included.	• Residual changes to Community and Public Health due to long hours, tight deadlines, and physically demanding tasks, leading to stress and fatigue; potential for social disconnection and emotional strain from extended periods away from families; employment disparities; and sensory disturbances and restricted land access.	• Context: Possible negative mental health effects. • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: High • Significance: Not Significant • Confidence: Low
• **Community and Public Health**	• Construction	• Negative effects from increased risk of substance use.	• Owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, which could include topics in relation offering mental health supports, counselling and addiction support services. • All construction workers (including on- and off-reserve members) will be housed in autonomous work camps to limit demographic shifts and limit disruptions to social structures and community dynamics. • Owner / operator to develop and implement monitoring and enforcement, including regular security checks at work camps and entry points (for example, airport) for alcohol and substances to prevent entry into the community.	• No adverse residual effect anticipated.	• No residual effect anticipated.

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
			• Owner / operator to collaborate with the community (Marten Falls First Nation and Aroland First Nation) to provide mental health counseling, addictions counseling, mentorship, and peer support at work camps, with onsite Elders or cultural liaisons to promote emotional and cultural well-being. • Owner / operator to enforce a zero-tolerance policy for alcohol and substance use at work camps. • Owner / operator to implement a gradual work force integration for community members, introducing shorter workdays and shift rotations (for example, starting with 2-3 days on with a day or two break instead of 10 consecutive days) to ease new workers into construction roles. • v to provide cultural safety training for all workers, including supervisors and non-Indigenous employees, to complete training on Indigenous culture, traditions, and historical experiences, to promote a safe and inclusive work environment. • Owner / operator to hold training session on violence and harassment prevention. • Owner / operator to enforce a zero-tolerance policy for workplace discrimination so that Indigenous workers feel respected and included. • Owner / operator to provide cultural and recreational activities (for example, cards, board games, sports), when possible, to promote well-being and reduce boredom or stress-related substance use.		
• **Community and Public Health**	• Operations	• Positive effect on health due to improved access to health services	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community and Public Health**	• Operations	• Positive effect on recreation due to improved access with other communities and recreational / event areas.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community and Public Health**	• Operations	• Positive effect on mental health and well-being due to improved access to mental health services and reduced isolation.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Community and Public Health**	• Operations	• Negative effect on mental health and well-being due to loss of connectivity to the land, change in sense of place and identity due to presence of the road.	• Owner / operator and owner to form a Working Group with Marten Falls First Nation, Aroland First Nation and the owner / operator to co-develop a Safety and Wellness Plan that addresses project-related mental health and well-being concerns.	• Residual changes to Community and Public Health due to loss of connectivity to the land, change in sense of place and identity due to presence of the road.	• Context: Decrease in mental well-being • Direction: Negative • Magnitude: Medium • Geographic Extent: Local • Duration: Long-term • Frequency: Continuous • Reversibility: Reversible • Likelihood: Possible • Uncertainty: High • Significance: Significant • Confidence: Low

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Community and Public Health**	• Operations	• Negative effect due to potential increase in substance use due to easier access to drugs and alcohol.	• Owner / operator to form a Working Group with Marten Falls First Nation, Aroland First Nation and the owner / operator to co-develop a Safety and Wellness Plan that addresses project-related substance use concerns.	• Residual changes to Community and Public Health due to potential increase in substance use due to easier access to drugs and alcohol.	• Context: Increase in substance abuse. • Direction: Negative • Magnitude: Medium • Geographic Extent: Local • Duration: Long-term • Frequency: Continuous • Reversibility: Reversible • Likelihood: Possible • Uncertainty: High • Significance: Significant • Confidence: Low
• **Community and Public Health**	• Operations	• Positive effect due to improved access to addictions treatment options.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Access to Clean Water**	• Construction	• Negative effect due to increased demand for drinking water.	• Construction workers will be housed in autonomous work camps, reducing pressure on community water resources. • Owner / operator to implement temporary water storage tanks or other measures to accommodate peak water demands during construction.	• No adverse residual effect anticipated.	• No adverse residual effect anticipated. • Significance: Not Significant • Confidence: High
• **Access to Clean Water**	• Construction	• Negative effect on quality of surface and / ground water as a result of construction, accidents, and spills.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area—including Constance Lake First Nation, Fort Albany First Nation, Attawapiskat First Nation, Kashechewan First Nation, Kasabonika Lake First Nation, Kitchenuhmaykoosib Inninuwug First Nation, Kingfisher Lake First Nation, Eabametoong First Nation, Mishkeegogamang First Nation, Neskantaga First Nation, Nibinamik First Nation, Wapekeka First Nation, Wawakapewin First Nation, Webequie First Nation, Weenusk First Nation, Wunnumin Lake First Nation, Animbiigoo Zaagi'igan Anishinaabek, Ginoogaming First Nation, and Long Lake #58 First Nation—to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including concerns related to contamination of ground and surface water. • Surface water and groundwater is not to be used as potable water. Water treatment will mitigate any potential negative effects.	• Residual changes to access to clean water as a result of construction, accidents, and spills.	• Context: Possible negative effect on quality of drinking water • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local study area • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: High • Significance: Not Significant • Confidence: Moderate
• **Access to Clean Water**	• Operations	• Positive effects on access due to lower transportation costs for shipping drinking water; improved supply chain reliability, and enhanced maintenance of the water treatment plant.	• No mitigation measures proposed	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Access to Clean Water**	• Operations	• Negative effect on quality of drinking water as a result of road operations, accidents, and spills.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including concerns related to contamination of ground and surface water. • Surface water and groundwater is not to be used as potable water. Water treatment will mitigate any potential negative effects.	• Residual changes to Access to Clean Water as a result of road operations, accidents, spills.	• Context: Possible negative effect on quality of drinking water • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local study area • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Possible • Uncertainty: High • Significance: Not Significant • Confidence: Moderate

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Traditional Foods**	• Construction	• Positive effect on access to traditional foods as increased income from construction jobs will allow community members to buy supplies for hunting and trapping.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Traditional Foods**	• Construction	• Negative effect of reduction in availability of traditional foods due to construction disturbances to traditional food sources.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including identifying key harvesting areas to implement measures that can minimize construction disturbances to traditional food resources during harvesting seasons and adjusting construction activities to avoid peak harvesting periods. • Owner / operator should provide flexibility in work schedules during key hunting, trapping, and gathering seasons to support continued access to traditional food sources.	• Residual changes to Traditional Foods due to construction disturbances to traditional food sources.	• Context: Possible disturbance to traditional food sources from construction-related activities • Direction: Negative • Magnitude: Low • Geographic Extent: Local • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: High • Significance: Not Significant • Confidence: Low
• **Traditional Foods**	• Construction	• Negative effect on the quality of traditional foods due to contamination.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including identifying key harvesting areas to implement measures that can minimize construction disturbances to traditional food resources during harvesting seasons and adjusting construction activities to avoid peak harvesting periods.	• Residual changes to Traditional Foods due to contamination.	• Context: Possible disturbance to traditional food sources from construction-related activities • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: High • Significance: Not Significant • Confidence: Low
• **Traditional Foods**	• Operations	• Positive effect of increased access to traditional harvesting sites	• No mitigation measures proposed	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Traditional Foods**	• Operations	• Negative effect of reduction in availability of traditional foods due to overharvesting and environmental strain from the road	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including discussions about pathways to contamination through traditional foods and opportunities to prevent contamination for example signage related to washing dust off gathered foods. • Owner to work with Ontario's Ministry of Natural Resources to encourage more frequent patrols of Conservation Officers along the Community Access Road to confirm hunters and fishermen are not exceeding their limits and that they have the proper tags and licenses. • Owner / operator to work with communities and governments, as required, to support education and development of Indigenous Conservation Officer (Game Warden) program. • Owner / operator to sponsor community-led harvesting initiatives in Marten Falls First Nation and Aroland First Nation.	• Residual changes to Traditional foods due to overharvesting and environmental strain from the road.	• Context: Possible disturbance to traditional food sources from the road or overharvesting • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Long-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: High • Significance: Not Significant • Confidence: Low

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Traditional Foods**	• Operations	• Positive effect of reduced cost of groceries and improved access to fresher, higher-quality foods.	• No mitigation measures proposed	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Traditional Foods**	• Operations	• Negative effect on the quality of traditional foods due to contamination.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including discussions about pathways to contamination through traditional foods and opportunities to prevent contamination for example signage related to washing dust off gathered foods.	• Residual changes to Traditional Foods due to contamination.	• Context: Possible disturbance to quality of traditional food sources • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Possible • Uncertainty: High • Significance: Significant • Confidence: Low
• **Public Safety**	• Construction	• Negative effect that demand for workers with Driver's licences exceeds those available.	• Explore opportunities to increase total Driver Licence holders, alongside the Ministry of Transportation, including partnerships with third-party remote licence providers.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Public Safety**	• Construction	• Negative effect of increased traffic and road-related injuries	• Develop Equipment Mobilization Plans with local First Nations for the movement of equipment, personnel, and supplies. • Implement driver safety training tailored to winter road conditions and remote community travel.	• Residual change to Public Safety due to increased traffic and road-related injuries.	• Context: Increase in construction-related traffic • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Probable • Uncertainty: Low • Significance: Not Significant • Confidence: High
• **Public Safety**	• Construction	• Negative effect of increased strain on emergency services.	• Develop, with the Ministry of Health, onsite safety and emergency preparedness programs to include fire suppression systems, medical care, security personnel, monitor safety compliance, emergency response and clear communication protocols between construction teams and emergency responders. • Comply with all relevant health and safety requirements, including but not limited to, preparation of a Health and Safety Policy.	• Residual changes to Public Safety due to increased strain on emergency services.	• Context: Increased strain on emergency services • Direction: Negative • Magnitude: Low • Geographic Extent: Local • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: Low • Significance: Not Significant • Confidence: High

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Public Safety**	• Construction	• Negative effect of increased risk of violence and harassment.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including: • financial literacy programs for workers and families to help manage income fluctuations and reduce financial stress, addressing economic disparities that could contribute to resentment and lateral violence. • measures to strengthen cultural programming and land-based activities to reinforce community cohesion and well-being. Strengthening cultural identity and offering community-driven programs can provide positive coping mechanisms for workers and families experiencing stress due to shift work and can offer a protective factor against violence and social disruption by strengthening support networks and reducing isolation. • supports for unemployed community members by identifying employment barriers and offering job readiness programs to support community members facing unemployment. • House workers in autonomous work camps to limit unsupervised interactions with the community and prioritize gender-divided living quarters in the work camps. • Enforce zero-tolerance policies for harassment and violence. • Provide cultural safety and language awareness training for all workers, including supervisors and non-Indigenous employees, to complete training on Indigenous culture, traditions, and historical experiences to understand Indigenous cultural norms and appropriate community interactions to reduce instances of harassment or violence. • Comply with the Human Rights Code (Ontario, 2024b) to prevent workplace discrimination and uphold employee rights to reduce work force tensions. • Mental health counseling, mentorship, and peer support at work camps to reduce stress-related aggression. On-site Elders or cultural liaisons will offer emotional support and traditional guidance to workers. • Implement a gradual work force integration for community members, starting with shorter workdays and shift rotations. • Implement Diversity, Equity, and Inclusion hiring policy.	• Residual changes to Public Safety due to increased risk of violence and harassment.	• Context: Occasional workplace conflicts, ongoing family stress from shift work, and potential lateral violence from economic disparities • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Short-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: Low • Significance: Not Significant • Confidence: Moderate
• **Public Safety**	• Operations	• Positive effect of increased demand for employment opportunities requiring a driver's license.	• No mitigation measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Public Safety**	• Operations	• Negative effect of increased in road-related injuries due to increase in road traffic.	• Owner / operator will establish a working group with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the operations of the Community Access Road, including advocating for funding to build a local fire station, recruit paramedics, and expand medical transport services; develop emergency preparedness plans, first responder training programs, and informing in independent medical providers (for example, dentists and physiotherapists) for potential for increased demand. • The owner to engage with law enforcement to implement increased monitoring; prepared for the opening of the road, allowing for an increased presence to monitor traffic, enforce speed limits, and deter impaired or reckless driving. • The owner to consider alternative methods to using salt on roads to prevent attracting wildlife, minimizing the potential for vehicle-wildlife collisions. • The owner to consider the installation of road signage in both English and traditional languages indicated speed limits, sharp turns, wildlife crossings, and other hazards.	• Residual changes to Public Safety due to increase in road traffic.	• Context: Increased traffic may lead to increased number of accidents Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Continuous • Frequency: Infrequent • Reversibility: Irreversible • Likelihood: Probable • Uncertainty: Low • Significance: Not Significant • Confidence: High

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Public Safety**	• Operations	• Positive effect of improved access to emergency services.	• No mitigation or enhancement measures proposed.	• No adverse residual effect anticipated.	• No residual effect anticipated.
• **Public Safety**	• Operations	• Negative effect of increase in violence and harassment.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including, could include the consideration of developing community-based violence prevention programs, including safe shelters and crisis support for victims; strengthening mental health, addictions, harm reduction programs, and family support services to address root causes.	• Residual changes to Public Safety due to increase in violence and harassment.	• Context: Potential for increase in violence, harassment, criminal activity, and / or human trafficking. • Direction: Negative • Magnitude: Moderate • Geographic Extent: Local • Duration: Continuous • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Possible • Uncertainty: Low • Significance: Significant • Confidence: Moderate
• **Biophysical Determinants of Human Health - Air** Note* Additional information regarding effects as they relate to human health can be found in the Problem Formulation in Appendix T.	• Construction • Operations	• Negative effects due to emissions to air and generation of dust. Leaks and spills of volatile substances can contaminant air.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction or operations of the Community Access Road, including concerns related to the biophysical effects on human health during construction, such as air, noise and vibration, sediment, soil, ground and surface water, and human land-use.	• Residual changes to human health due to emissions to air and generation of dust. Leaks and spills of volatile substances can contaminant air.	• Context: Impacts to air can be carried by wind • Direction: Negative • Magnitude: High Magnitude • Geographic Extent: Construction Disturbance Area • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversibly • Likelihood: Possible • Uncertainty: Air deposition rates and maximum modelled air concentrations are not available from Technical Support Document for Air. Chemical concentrations in aggregate source for road (source of dust) not available from technical support document for soils.
• **Biophysical Determinants of Human Health - Noise**	• Construction • Operations	• Negative effects of unacceptable noise and vibration levels.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction or operations of the Community Access Road, including concerns related to the biophysical effects on human health during construction, such as air, noise and vibration, sediment, soil, ground and surface water, and human land-use.	• Residual changes to human health due to unacceptable noise and vibration levels.	• Context: Noise from blasting, quarrying, road construction, traffic and maintenance activities. • Direction: Negative • Magnitude: High • Geographic Extent: Construction Disturbance Area • Duration: Long-term • Frequency: Infrequent • Reversibility: Reversible • Likelihood: Certain • Uncertainty: Noise technical support document does not contain information on maximum noise levels expected for construction or maintenance or on distance noise may travel. Predicted traffic noise levels are within acceptable levels.

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Biophysical Determinants of Human Health - Sediment**	• Construction • Operations	• Negative effects due to deposition of dust or runoff into waterbodies could cause contamination of sediment; leaks and spills can contaminate sediment.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction or operations of the Community Access Road, including concerns related to the biophysical effects on human health during construction, such as air, noise and vibration, sediment, soil, ground and surface water, and human land-use.	• Residual changes to human health due to deposition of dust or runoff into waterbodies could cause contamination of sediment; leaks and spills can contaminate sediment.	• Context: Impacts to sediment can occur subsequent to impacts to surface water. • Direction: Negative • Magnitude: Moderate • Geographic Extent: Construction Disturbance Area • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Possible • Uncertainty: Air deposition rates and maximum modelled air concentrations are not available from Technical Support Document for Air. Chemical concentrations in aggregate source for road (source of dust) not available from technical support document for soils.
• **Biophysical Determinants of Human Health - Soils**	• Construction • Operations	• Negative effects due to deposition of dust could cause contamination of soils. Elevated background concentrations of metals in aggregate source areas could result in elevated concentrations in metals in dust generated, leaks and spills can contaminate soils.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction or operations of the Community Access Road, including concerns related to the biophysical effects on human health during construction, such as air, noise and vibration, sediment, soil, ground and surface water, and human land-use.	• Residual changes to human health due to deposition of dust could cause contamination of soils. Elevated background concentrations of metals in aggregate source areas could result in elevated concentrations in metals in dust generated, leaks and spills can contaminate soils	• Context: Contaminants in aggregate will impact air quality. Air impacts can be carried by wind. • Direction: Negative • Magnitude: Moderate • Geographic Extent: Construction Disturbance Area • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Possible • Uncertainty: Chemical concentrations in aggregate source for road (source of dust) not available from technical support document for soils. Air deposition rates and maximum modelled air concentrations are not available from Technical Support Document for Air
• **Biophysical Determinants of Human Health – Groundwater**	• Construction • Operations	• Negative effect due to deposition of dust or runoff / infiltration into groundwater could cause contamination of water potentially used for drinking, bathing, or cooking. Leaks and spills can contaminate groundwater.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction or operations of the Community Access Road, including concerns related to the biophysical effects on human health during construction, such as air, noise and vibration, sediment, soil, ground and surface water, and human land-use.	• Residual changes to human health due to deposition of dust or runoff / infiltration into groundwater could cause contamination of water potentially used for drinking, bathing, or cooking. Leaks and spills can contaminate groundwater.	• Context: Groundwater may be source of potable water at camps. Some groundwater concentrations exceed drinking water standards. • Direction: Negative • Magnitude: High • Geographic Extent: Construction Disturbance Area • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Possible • Uncertainty: Chemical concentrations in aggregate source for road (source of dust) not available from technical support document for soils.

• **Biophysical Determinants of Human Health – Human Land Use**	• Operations	• Possible negative effect of increase in durations, extent, frequency and seasons spent engaged in land-use within the Local Study Area.	• Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, to meet regularly to discuss community-proposed topics in relation to the construction or operations of the Community Access Road, including concerns related to the biophysical effects on human health during construction, such as air, noise and vibration, sediment, soil, ground and surface water, and human land-use.	• No residual effect anticipated.	• No residual effect anticipated.

9.5.7 Land and Resource Use

9.5.7.1 Project-Environment Interactions

An analysis of Project-environment interactions for community well-being that are likely to have a potential effect is provided in **Table 9.5-34**.

Table 9.5-34: Project-Environment Interactions – Land and Resource Use

Project Phases	Project Activities to Have Potential Effect on Land and Resource Use
• **Construction**	• Mobilization of Equipment and Supplies • Temporary Construction Staging Areas • Temporary Access Roads and Trails • Temporary Construction Camps • Right-of-way Clearing and Grubbing • Brush and Timber Disposal • Pits and Quarries • Temporary Concrete Batch Plants / Trails and Staging Areas • Drilling / Blasting / Aggregate Production • Road Construction (stripping, subgrade excavation, embankment fill placement, grading, ditching) • Bridge and Culvert Installation (approach embankments, foundations, substructures, superstructures, traffic protection, erosion controls) • Construction Site Restoration • Pits and Quarries
• **Operations**	• Road Usage • Road Maintenance

9.5.7.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following land and resource use definitions apply to the effects assessment.

Ecological and Social Context

The ecological context within which potential environmental, health, social, and economic effects may occur has been taken into account when considering the effects criteria, such as species sensitivity and resilience, and includes Indigenous Knowledge where it was available.

The social context of the effect includes a discussion of the social and cultural consequences of the predicted effect. The current and future sensitivity and resilience of the valued component to change caused by the Community Access Road has also been considered. The assessment includes the level of sensitivity and / or resilience.

Magnitude

For magnitude, environmental discipline-specific definitions are provided below in **Table 9.5-35**.

Table 9.5-35: Land and Resource Use Magnitude Definition

Magnitude Level	Definition	Rationale
• **Negligible**	• An effect that may or may not be discernible but is within the historical variability as defined by existing conditions. The effect is within the capacity of the Land and Resource Use system to respond and / or will not alter the current Land and Resource Use structures.	• Negligible effects are small and may not be noticeable. These effects do not represent a change in day-to-day Land and Resource Use.
• **Low**	• An effect that is small but discernable and within historical variability as defined by existing conditions. The effect is within the capacity of the Land and Resource Use system to respond and / or will not alter the current Land and Resource Use structures.	• Low effects are noticeable to some land and resource users. These effects do not represent a change in day-to-day activities.
• **Medium**	• An effect that is clearly discernable and beyond the historical variability as defined by existing conditions. The effect is within the capacity of the Land and Resource Use system to respond and / or will not alter the current Land and Resource Use structures.	• Medium effects are noticeable to some land users. These effects may or may not represent a change to day-to-day activities but can be adjusted to within the current Land and Resource Use system.
• **High**	• An effect that is clearly discernable and beyond the historical variability as defined by existing conditions. The effect is beyond the capacity of the Land and Resource Use system to respond and / or will alter the current Land and Resource Use structures.	• High effects are noticeable to land and resource users. These effects represent a change to day-to-day land use. In the case of adverse effects, these changes cannot be responded to within the current land and resource system resulting in systemic change.

9.5.7.3 Residual Effects - Construction Phase

9.5.7.3.1 Land Use Compatibility

9.5.7.3.1.1 Potential Effects

The Construction Disturbance Area is located on lands under jurisdiction of the *Far North Act* and the *Public Lands Act*. The Marten Falls First Nation Draft Community-Based Land Use Plan was considered as part of the effects assessment.

The Construction Disturbance Area overlaps with 1,257.1 hectares of lands identified as Dedicated Protected Area land use designation within the Marten Falls First Nation's Draft Community-Based Land Use Plan. The Draft Community-Based Land Use Plan has not been finalized or approved and continues to be developed. The land use designations and permitting land use activities within the Community-Based Land Use Plan, including the Dedicated Protected Area, are being developed in a manner that considers the proposed Community Access Road, associated aggregate sites, and supporting infrastructure. At the time of writing this report, the proposed route has not been withdrawn from mining claims.

Portions of the Preferred Route fall within lands that are managed by the Ministry of Natural Resources under Crown land management direction for Geraldton Area (general use area) through the Crown Land Use Policy Atlas. The Crown Land Use Policy Atlas provides policy direction for Crown Land use and in this area identifies permitted uses, including road development and aggregate extraction, subject to applicable approvals and permitting requirements. Existing land uses such as commercial outpost camps are administered under the *Public Lands Act*. As such, the types of infrastructure associated with the Community Access Road are consistent with existing Crown land use policy direction applicable to the area.

The majority of the Preferred Route falls within the Far North. In accordance with Section 14 of the *Far North Act*, existing rights for the acquisition, disposition, use or occupancy of public lands and activities associated with these uses (such as, commercial outpost camps) remain valid where they were established prior to the finalization of a community-based land use plan. As such, no land use compatibility associated with the Far North or *Public Lands Act* will have potential effects.

9.5.7.3.1.2 Mitigation and Enhancement Measures

The Marten Falls First Nation Draft Community-Based Land Use Plan remains under development and has not been finalized or approved. Land use designations and permitted land use activities, including those associated with Dedicated Protected

Areas, continue to be developed in a manner that contemplates the Community Access Road, associated aggregate sites, and supporting infrastructure.

In the interim, Crown land use decisions will continue to be guided by applicable provincial legislation and policy, including the *Far North Act*, the *Public Lands Act*, and direction provided through the Crown Land Use Policy Atlas. Once finalized, the Marten Falls First Nation Community-Based Land Use Plan will provide additional land use direction consistent with established planning processes.

Given the potential for new development opportunities that may arise as a result of improved access provided by the Project, it is recommended that Marten Falls First Nation and Aroland First Nation be involved in land and resource use planning discussions related to future development within areas of shared or overlapping traditional territories, in accordance with applicable Crown processes.

9.5.7.3.1.3 Predicted Residual Effects

No residual effects on land use legislation, policies, or plans are anticipated during construction.

9.5.7.3.2 Ontario Parks and Protected Areas

9.5.7.3.2.1 Potential Effects

The Construction Disturbance Area transects the Albany River Provincial Park. Approximately 5.7 hectares of Park land would be affected during construction, with a road length of approximately 0.6 kilometres through the Park. A new bridge would also be constructed to cross the Albany River.

These activities represent a direct adverse effect related to vegetation removal and localized disturbance within the Park. From a geographic perspective, the area effected represents a very small proportion of the overall Park area. The Albany River will remain navigable for the types of watercraft typically used in the area.

Recreational activities within the Albany River Provincial Park include occasional canoeing, kayaking and sport fishing. Due to the remote nature of the park, recreational use is limited and difficult to quantify. During construction, users in proximity to the bridge crossing may experience temporary noise effects. Construction noise levels at the bridge crossing location may reach up to 70 A-weighted decibels, decreasing to approximately 30 A-weighted decibels at a distance of 5 kilometres, over a period of up to two years. No campsites are located within the Construction Disturbance Area; however, there is a 40 metres portage used to bypass Snake Rapids located in the proposed crossing construction area. Park users may also experience noise from aggregate extraction at pits

located on the south side of the Park just west of the proposed crossing location. Continued engagement with Ontario Parks will be completed through the detail design so ample notification to Park users can be provided.

The sequence of construction will be completed in a phased in approach. Construction will occur in phases, and localized construction-related effects will decrease as work progresses beyond the Park. Temporary effects on air quality (for example, dust) may occur during construction. Further detail on air quality effects is provided in the Atmospheric Environment Technical Support Document found in **Appendix S**. The Preferred Route is located near, but does not intersect the Ogoki River Provincial Park. No direct land removal will occur within the Park. A limited amount of the most eastern end of the Park (about 500 metres) would experience noise effects greater than 45 A-weighted decibels, which is considered to be a noticeable change to the existing conditions.

The Ogoki River Provincial Park may experience temporary changes in air quality (dust) given the distance of the eastern park boundary to the Construction Disturbance Area (0.8 km).

Little Current River Provincial Park, Otoskwin–Attawapiskat River Provincial Park, Nakina Moraine Provincial Park, and the Jobes Creek Area of Natural and Scientific Interest are located at distances sufficient to preclude direct or indirect construction-related effects. Little Current River Provincial Park is located approximately 14.7 kilometres from the proposed road route and 3.7 kilometres from the southernmost aggregate pit site. Otoskwin–Attawapiskat River Provincial Park is located approximately 33.6 kilometres from the proposed road route and 37.1 kilometres from the northernmost aggregate pit site. Nakina Moraine Provincial Park is located approximately 61.3 kilometres from the proposed road route and 62.8 kilometres from the southernmost aggregate pit site. Jobes Creek Area of Natural and Scientific Interest is located 27.5 kilometres from the proposed road and aggregate sites that precludes construction-related noise or air quality effects. Further details are available in Atmospheric Environment Technical Support Document in (**Appendix S**).

No indirect effects related to this indicator were identified.

9.5.7.3.2.2 Mitigation and Enhancement Measures

Parks related mitigation and enhancement measures to be implemented during construction of the Project include:

- Refer to mitigations as outlined in the Atmospheric Environment Technical Support Document (**Appendix S**);

- Limit clearing and use of land within the Parks as much as possible. Temporary work areas such as staging areas should be located outside of parks;
- Monitor and limit the development of any side trails / roads that might extend into the parks. Marten Falls First Nation and the Owner of the road will engage with Ontario Parks to determine any measures to control access into parks and protected areas where applicable and refer to the amended Albany River Provincial Park Management Statement; and,
- Continued engagement between Ontario Parks, Marten Falls First Nation and the owner of road should continue into the detail design phase to encourage bridge designs that could commemorate the culturally significance and history of the Albany River waterway.

9.5.7.3.2.3 Predicted Residual Effects

Residual effects considered include vegetation removal, noise, air quality, visual effects, and changes in access.

Albany River Provincial Park will experience minor adverse residual effects, including localized vegetation removal (5.7 hectares), temporary construction-related noise and air quality effects, and a localized reduction in wilderness character due to bridge visibility. These effects are limited in geographic extent, largely reversible, and affect a small proportion of the Park.

Noise and air quality effects during construction are short-term and localized. No designated campsites occur within the affected area. Effects on other provincial parks and protected areas are not anticipated due to distance from the Project.

Considering the ecological and social context, magnitude, geographic extent, duration, and reversibility of effects, residual effects on Parks and Protected Areas are assessed as not significant**.**

9.5.7.3.3 Recreation and Tourism

9.5.7.3.3.1 Potential Effects

The road, which will be approximately 184 kilometres, has the potential to improve access to remote Crown land and water resources if opened for public use. Improved access could provide new recreation and tourism opportunities, including camping, snowmobiling, hunting, fishing, and canoeing / kayaking, representing a potential beneficial effect on recreation and tourism.

In contrast to these benefits, increased access could adversely affect some remote outfitter operations.

Aroland First Nation and other community members have indicated their preference for controlled access along the road, which if implemented, would limit access to the public. At this stage, access arrangements have not been finalized and will depend on future decisions by the road owner and applicable authorities.

Considering the road will not have many secondary roads or trails at the time of construction, recreational access is expected to occur primarily via waterways during the spring, summer and fall months, while winter months could attract snowmobiling.

The development of bridges and culverts over watercourses could potentially affect navigation (for safety purposes) during construction of the Project. Clear span bridges will be required at water crossings with bank full widths greater than 5 metres and less than 30 metres, and bridges with piers and abutments will be required at water crossings greater than 30 metres. Bridges will be designed to meet the 1 in 100-year flood scenario design, fish passage requirements, and navigable requirements, based on federal and provincial regulations. Water crossings that require either a clear span bridge or multi-span bridge can be found in the Surface Water Technical Support Document (**Appendix F**). Net effects to navigation are expected to be temporary during construction as navigation will be maintained on waterways determined to be navigable during operations. Required permits under the Canadian Navigable Waters Act will be obtained prior to construction.

The construction the Project could result in disruption effects and enjoyment to recreation and tourism activities (for example, disturbances from changes in noise, vibration, air quality, and viewscapes).

There are no formal campgrounds in the Construction Disturbance Area, however, there is a portage located close to the proposed Albany River Bridge crossing which would be maintained during construction (navigability). Recreation features in the Local Study Area include water access recreation such as canoeing and boating.

Due to the remote nature of the Local Study Area and limited existing access, recreational use outside provincial parks and remote outfitter areas is understood to be limited. While noise and air quality changes will occur in close proximity to the road and ancillary facilities (aggregate pits) during the construction, effects on recreational use are assessed as localized, intermittent, and low in magnitude for both construction and operation due to the low number of visitors.

The sequence of construction will be completed in a phased in approach. Once construction of a given road length is complete, construction will move along the Construction Disturbance Area, and the magnitude of the impact will decrease over time. These localized periods of construction will have potential for effects on air quality, due to Nitrogen Dioxide, Sulfur Dioxide, Carbon Monoxide, Total Suspended Particulates and Particulate Matter 2.5 and 10 emissions. Further detail on air quality effects is provided in the Atmospheric Environment Technical Support Document (**Appendix S**).

The development of the Project could influence the availability of species harvested for recreational purposes through localized habitat removal and changes in access to lands and waterways used for hunting and fishing. Habitat removal associated with the Project is expected to be limited in extent and localized to the Construction Disturbance Area.

Improved access resulting from the Project could increase recreational hunting and fishing opportunities in the vicinity of the road. From a recreation and tourism perspective, effects are expected to be related primarily to changes in access and user distribution rather than Project-related changes in overall species abundance.

Potential effects related to wildlife habitat, species abundance, population dynamics, and sustainability are assessed under the wildlife, ungulates, and fish valued components. Wildlife and fish populations are managed through existing provincial programs administered by the Ministry of Natural Resources.

9.5.7.3.3.2 Mitigation and Enhancement Measures

Typical mitigation and avoidance measures such as standard practices for camp construction, road and water crossing construction will be applied during construction of the Project. Such measures include:

- Design and installation of water crossing structures to accommodate flow, drainage, fish passage (where applicable), and navigability requirements in accordance with federal and provincial regulations;
- Minimization of vegetation clearing to areas required for construction, staging, and operations;
- Progressive reclamation and revegetation of disturbed areas no longer required following construction (for example, temporary access roads, construction camps, and laydown areas);
- Restriction of public access during construction for safety reasons;

- Provision of signage along the Preferred Route to support safe interaction between road users and recreational users; and
- Coordination with Ontario Parks and relevant authorities where recreational features (for example, portages, waterways) may be affected.
- Rehabilitation and revegetation of areas disturbed during construction but are no longer deemed necessary for operations will promote wildlife species to return to the area.
- Mitigation measures related to fish and fish habitat and wildlife originate from the Fish and Fish Habitat Technical Support Document (**Appendix G**) and Ungulates Technical Support Document (**Appendix M**) and are addressed under those valued components. Additional mitigation and monitoring related to wildlife populations, hunting pressure, and fish harvest will continue to be managed through existing provincial programs.
- Vegetation clearing limits, buffer zones, and erosion and sediment control measures associated with waterbodies will be implemented in accordance with Project design requirements and applicable regulatory approvals.

9.5.7.3.3.3 Predicted Residual Effects

The amount of recreation activity that occurs on crown land within the Construction Disturbance Area is limited due to the remote nature of the area and the lack of access.

Potential construction noise effects on crown land potentially used for recreation were assessed to be local in geographic extent and short-term / reversible. No recreation receptor locations were identified. These effects are considered to be not significant.

As a result, adverse residual effects on Recreation and Tourism are assessed as not significant.

9.5.7.3.4 Extractive Resource Industry

9.5.7.3.4.1 Potential Effects

Removal of lands with potential for mineral extraction, as measured through area of land under mining claims that the road segments pass through.

Within the Construction Disturbance Area there are 2,234 hectares of existing mining claims, which could be affected by the road and associated Project components. Two mining companies will be affected by the development of the Community Access Road: Wabassi Resources and Canada Chrome Corporation.

Based on interviews with claim holders including Wabassi Resources and KWG Resources, no specific preferences were provided during the route selection phase. Claim holders were advised of the Preferred Route in Fall 2024 with a request for comments. Additional letters were sent in spring 2025 requesting feedback on the Preferred Route, no comments were received from these letters, neither company commented on the Draft Environmental Assessment / Impact Statement. As such, it is assumed that the deposits in the affected claims are large enough to provide flexibility in the development of future mines. Therefore, negligible adverse effects to mineral development are anticipated from the Project.

It is noted that an aggregate pit is located on the site of an existing Wabassi Resources exploration camp that is under a lease from the Ministry of Natural Resources. It is not known how long this exploration camp is set to operate. Further consultation is required with Wabassi Resources to better understand this camp and potential impacts to it from this Project.

9.5.7.3.4.2 Mitigation and Enhancement Measures

Mining companies have indicated their support of the Project due to the increased accessibility that would result allow for development of future mines from these mining claims.

Mitigation and enhancement measures for the extractive resource industry include engaging with mining claim holders in the road design stage to determine how impacts to any mineral deposits can be minimized and / or how the Project can help to support their activities.

9.5.7.3.4.3 Predicted Residual Effects

The Construction Disturbance Area intersects approximately 2,234 hectares of existing mining claims, resulting in a localized adverse residual effect related to land occupation and potential constraints on mineral development.

Engagement with affected claim holders did not identify specific concerns regarding the Preferred Route or indicate that the Project would preclude future mineral exploration or development. The road occupies a limited portion of the affected claims, and mining activities could continue to be planned and permitted following construction, subject to applicable regulatory approvals.

Improved access resulting from the Project represents a beneficial effect for the extractive resource industry by facilitating future exploration and development opportunities; however, the realization of these benefits would depend on separate project proposals, regulatory approvals, and market conditions.

Considering the limited spatial extent of overlap, the absence of identified constraints on mineral development, and the increased accessibility to claim areas, adverse residual effects on the Extractive Resource Industry are assessed as not significant.

9.5.7.3.5 Forestry Industry

9.5.7.3.5.1 Potential Effects

The Ogoki Forest is approximately 1,087,986 hectares in size. The Construction Disturbance Area overlaps 384.4 hectares of the Ogoki Forest (bog, forest, marsh, swamp, water, rock, fen, and anthropogenic). Of that, 195.4 hectares of forest (coniferous, deciduous, early successional / sparse treed, and mixed) would be removed through construction of the road and potential development of two aggregate pits. There is the potential for direct effects on the Ogoki Forest via removal of commercial forestry land during construction, however, given the percentage of the area affected (roughly 0.04 percent of the total area of the Ogoki Forest), this effect is expected to be negligible. The Project has the potential to increase access to lands northeast of the Ogoki Forest that could contain merchantable timber stands resulting in a positive Project effect.

Due to the lack of actively harvested forestry lands within the Construction Disturbance Area outside of the Ogoki Forest, the Project will have minimal adverse direct or indirect effects to this valued component. Forestry companies were advised of the Preferred Route in Fall 2024 and Spring 2025 with a request for comments.

9.5.7.3.5.2 Mitigation and Enhancement Measures

While not anticipated, should any commercial forest trees be felled within the Ogoki Forest Management area for Construction, the value of the timber will be determined and be the responsibility of the Sustainable Forest Licence holder to dispose of.

Areas outside of the Ogoki Forest that are to be cleared for construction will require to be scaled for its value and the Proponent should consult with the Ministry of Natural Resources to determine options for the harvested timber. Any timber that is deemed merchantable (anything greater than 10 centimetres diameter outside the bark) must be valued. Area that does not have a Forest Management Unit, a permit must be granted to the Proponent to harvest the trees and to properly sell or dispose of.

9.5.7.3.5.3 Predicted Residual Effects

Adverse residual effects on the Forestry Industry are not expected, as the Construction Disturbance Area overlaps approximately 0.24 percent of the Ogoki Forest, representing a negligible to low magnitude effect relative to the overall forest

management unit. Any merchantable timber removed for the Project will be managed and compensated in accordance with applicable Crown forest management requirements.

Given the limited spatial extent of overlap, the short duration of clearing activities, and the capacity of existing forest management and compensation frameworks to address localized timber removal, residual effects on the Forestry Industry are assessed as not significant.

9.5.7.3.6 Remote Outfitters

9.5.7.3.6.1 Potential Effects

Information regarding commercial outpost camp land use permits potentially affected by the Project was collected from the companies (remote outfitters) operating these sites. Coordinates, screen shots, or descriptions were provided and then digitized. The descriptions of distances from the Construction Disturbance Area should be considered as being from the lake where the camp is located and not the actual location of the camp and are therefore approximate until outreach can be completed. Remote outfitters were advised of the Preferred Route in Fall 2024 and Spring 2025 with a request for comments.

Outfitters expressed concerns that the Project, if opened to the public, would allow greater access to their camp locations / areas of operations, potentially affect wildlife and fish populations, and result in their camps being less attractive to their customers (Andomoozwe Outfitters; Boreal Outfitters; Dusey River Outfitters; Gray Wood Outfitters; Tom's Outpost Camps; O'Sullivans Rainbow; Wilderness North; Nakina North Outfitters; Hearst Air; Leuenberger Air Service, personal communication, 2022). The remote outfitters indicated that users with a specific interest in visiting remote outfitting camps may no longer be interested if a road providing access replaces flights.

Six remote tourism outfitter camps were identified closest to the Project location, within 5 km of the Construction Disturbance Area:

- Esser Lake (Twin Lake Outfitters): 4.3 kilometres
- Painter Lake (Leuenberger Air Service): 0.5 kilometres
- Percy Lake (Leuenberger Air Service; Nakina North Outfitters): 4.8 kilometres
- Painter Lake (Leuenberger Air Service): 4 kilometres
- Caviar Lake (Leuenberger Air Service): 0.9 kilometres
- Leuenberger's Teabeau Site: 4.4 kilometres

There are two types of Land Use Permits issued by the Government of Ontario: those for restricted (Type B) outpost camps (in other words, short term seasonal use; limited infrastructure) and Type A commercial outpost camps (in other words, long term use year after year; permanent infrastructure). Though the Construction Disturbance Area does not directly overlap any remote outfitter camps, changes to the land resulting from both construction and operation of the Project may result in less people using these services. There were no restricted (type B) Land Use Permits identified in the Construction Disturbance Area, given that these types of Land Use Permits are set up in the same areas annually, it is not anticipated that these would be impacted. Unless explicitly noted in the Land Use Permit's Standard Conditions, restricted Land Use Permits expire after hunting seasons close for that year. Remote outfitters are then responsible for reapplication. Given that there were none identified, there would be no impact to these types of Land Use Permits.

Changes in environmental conditions, including air quality, noise, visual, surface water, fish abundance / distribution, wildlife abundance distribution, as well as a change in access may cause indirect effects to remote outfitters. Changes related to environmental conditions may change the attractiveness of these camps to their client base. The following describes changes in environmental conditions in the vicinity of the noted camps.

Air Quality

Once construction of a given road length is complete, construction will move along the Construction Disturbance Area, and the magnitude of the impact will decrease over time. These localized periods of construction will have potential for effects on air quality, which can be found in the Appendix S.

It is expected that a high magnitude of particulate matter concentrations are predicted to impact recreational users within 3 kilometres from the road due to fugitive road dust generated from vehicular travel on the unpaved road during operations. However, this is based on the maximum vehicular traffic volume on the road occurring in 2046 (Appendix S) this level of traffic is not anticipated but was used to provide an uppermost limit for the impacts being considered. Painter Lake (if upgrades to the Painter Lake Road) and Caviar Lake camps are expected to be impacted by air quality given the results outlined above.

Noise

Commercial outpost camp locations could also experience noise effects from road construction and during operations which could detract from the user experience and make these camps less attractive to the outfitter and potentially their clients. **Table**

9.5-36 outlines the noise levels for the six camps closest to the Construction Disturbance Area and others that will be affected by noise during construction and operations of the Project.

Table 9.5-36: Noise Results for Remote Outfitter Camps, within 5 kilometres of Construction Disturbance Area

Camp	Construction Phase	Operations Phase
Esser Lake (Twin Lake Outfitters)	• Not applicable; outside impact area	• Outside impact area
Painter Lake (two camps) (Leuenberger Air Service)	• Less than 45 A-weighted decibels for road construction and 45 to 60 A-weighted decibels from aggregate pit construction	• Outside impact area; aggregate pit (ID14) north of Painter Lake to be used during construction only
Percy Lake (Leuenberger Air Service; Nakina North Outfitters)	• Not applicable; outside impact area	• Outside impact area
Caviar Lake (Leuenberger Air Service)	• 50 to 55 A-weighted decibels from road and bridge construction	• 30 A-weighted decibels approximately 1.5 kilometres from bridge location (exact location to be determined through outreach)
Teabeau (Leuenberger Air Service)	• 30 to 35 A-weighted decibels for a small eastern section of the lake / river	• Outside impact area

The Painter Lake camp and the Caviar Lake camp are likely to experience the highest impact from noise during construction and operation phases; however, noise levels are below or equal to the Health Canada Limit Guide of 55 A-weighted decibels.

Visual

With regards to visual effects as discussed in Appendix V of the Environmental Assessment / Impact Statement, Painter Lake and Caviar Lake are likely to experience the highest visual impact during construction and operation of the Project. Painter Lake is approximately 970 metres from the nearest aggregate site, if this site is utilized in the upgrades to the existing road infrastructure of Painter Lake Road. Caviar Lake's distance from the nearest aggregate site is 1.7 kilometres from the bridge crossing at the Albany River. It is not expected to be seen from the commercial outpost camp location but could potentially be seen while fishing along the river. The Caviar Lake site is also located 880 metres from an aggregate site. The kind of extraction activities at that aggregate site location will be determined during detail design.

Surface Water

As some remote outfitters offer fishing opportunities via boating, effects on surface water (for navigational purposes) are not anticipated to result in an adverse change beyond a manageable level. Some short-term effects may result in temporary impacts to navigation during construction to maintain public safety. Appropriate mitigation is discussed below.

Fish Abundance / Distribution

Northern pike, brook trout, and walleye may all experience effects from the Project, particularly during construction from loss of habitat (bridge construction) and saltation effects. Due to increased access to the area and to remote outfitting camps, there could be increased fishing pressure on the waterways in proximity to the road which could also adversely impact species abundance. Spills during the construction and operations in high enough concentrations may also negatively affect fish and fish habitat. However, fish populations are expected to be self-sustaining and ecologically effective and do not represent a substantial management concern (Appendix G) Appropriate mitigation will be required during construction and operations to reduce or avoid impacts to these species.

Wildlife Abundance Distribution

The Project is expected to result in an increase in public access and with potential for hunting opportunities for Indigenous and non-Indigenous hunters in the vicinity of the road during operations, which may lead to decreased moose abundance. Moose mortality risk from hunter harvest may increase, particularly for moose in Wildlife Management Unit 17 with home ranges near the Community Access Road (such as, local to regional effect). It is expected that hunting pressure will be monitored by the Ministry of Natural Resources and controlled through the issuance of hunting tags. It is also expected that there will be potential impacts from increase vehicular travel on the road which could impact wildlife populations.

Moose health may be impacted from the introduction of roads with concerns that increased access to the area resulting from the operation of the Community Access Road there could be an increase in illegal hunting / poaching. This could affect moose populations over time, which could result in impacts to the number of tag allocations a remote outfitter would receive for potential clients.

Change in Access

The construction of the road would mean that lands and waterbodies are more accessible to the public (if the road is not restricted) and decrease the attractiveness of

the area for remote tourism operations. Aroland First Nation has indicated their preference for controlled access along the road and have expressed they do not wish to have any new commercial outpost camps in the area.

Considering the above, construction of the Project is expected to contribute to a change in the remote / wilderness character of the area where some of the commercial outpost camps are located and could potentially reduce their attractiveness for clients, resulting in a decrease in business. The commercial outpost camps at most risk to this include: Painter Lake, due to a proposed aggregate pit on the north side of the lake; Caviar Lake, due to the crossing of the Albany River just to the east of the camp location (<1 kilometres and proposed pits to the south); and to a lesser extent Teabeau Lake, due to improved access to the Albany River and the potential for more boats / fishing in the area. Although the ownership of the road and the public versus restricted access of the road is unknown, there are potential noise impacts from vehicular traffic or aggregate operations. These commercial outpost camps may become less attractive, and the outfitters may decide to sell their camps and their moose tag shares. This is considered to be a direct adverse effect to these camps. Given the possibility of new access opportunities to the Caviar Lake and Teabeau Lake camps (accessible by boat via the Community Access Road) it may be possible to create boat in opportunities for these sites as they would no longer require fly-in access and be more economical for use. This would however require a boat launch for the area. At the time of writing this report, there are currently no design considerations for constructed access points for the Albany River.

9.5.7.3.6.2 Mitigation and Enhancement Measures

Proposed mitigation to minimize effects are as follows:

- Engage further with the impacted outfitters / camp owners (during detail design);
- Engage with the Province (Ministry of Natural Resources) to develop signage for hunting restrictions and to report poaching;
- Review options for access points at the Albany River Bridge Crossing;
- Marten Falls First Nation and the owner of the road should engage with Ministry of Natural Resources regarding how fish populations may be monitored;
- Provide at least one year notice to the remote outfitters in advance of construction start; and
- Implement mitigation measures for air quality, noise, visual, surface water, fish, wildlife, and ungulates as outlined in the appropriate technical support documents.

- Proposed mitigation to minimize effects on this valued component, as outlined in the Wildlife Technical Support Document (**Appendix K**) are as follows:
- The possession and use of firearms will not be permitted for construction personnel;
- The owner of the road may provide compensation for business losses to remote outfitters who are impacted by construction and operations of the Community Access Road;
- Restrict public access to the Community Access Road corridor during construction. Restrict temporary access roads and restore as soon as possible after they are no longer needed. Permanent access roads used for maintenance activities and aggregate pits will be gated while not in use;
- Develop and implement an Environmental Protection Plan that includes the following measures to control, and / or restrict public use of access roads during construction and operation: speed limits, signage, reduced road standard, natural berms across temporary access roads after reclaimed / rehabilitated, removal of temporary watercourse crossings, reduce traffic by locating camps near construction sites. Posting of restricted access and speed signage will follow the Construction Specification for Temporary Traffic Control Devices (Construction Specification for Temporary Traffic Control Devices, 2016).

9.5.7.3.6.3 Predicted Residual Effects

Adverse residual effects are anticipated for remote outfitting operations at Painter Lake, Caviar Lake, and Teabeau Lake as a result of increased access to the area, development of aggregate pits, and Project-related noise, particularly during construction. These effects are associated primarily with changes in access conditions and a localized reduction in wilderness character, which may influence the user experience for clients seeking fly-in, remote outfitting opportunities.

The magnitude of these effects on remote outfitting operations is assessed as low as effects are localized to areas in proximity to the road and aggregate sites and do not result in the physical removal of outfitting infrastructure.

Changes in access may result in increased presence of other land users in the area, which could further influence wilderness character and outfitter client experience. However, these effects are dependent on future access management decisions and user behaviour and are not expected to result in the displacement or closure of outfitting operations.

Effects related to the availability of species harvested for recreational hunting and fishing are not anticipated to be severe. Residual effects on fish and fish habitat were assessed as negligible to medium in magnitude and not significant in the fish and fish habitat valued component. Residual effects on moose and moose habitat were assessed as low to medium in magnitude, ranging from localized to regional in geographic extent, with populations expected to remain self-sustaining and ecologically effective. As such, effects on wildlife and fish availability relevant to outfitting operations are not expected to represent a substantial management concern.

Remote outfitting camps operate under Land Use Permits, which represent a limited tenure on Crown land. While this does not diminish the importance of outfitting operations, it indicates an existing level of exposure to changes in land use conditions. Camp operators will be provided with advance notice of construction activities (minimum one year), allowing for operational planning and adaptation. In addition, improved access may create opportunities for some operators to adjust service models (for example, drive-in or boat-access camps), partially offsetting adverse effects related to remoteness.

Considering the magnitude, duration, geographic extent, reversibility, and the capacity of outfitting operations to adapt, adverse residual effects on the remote outfitters valued component are assessed as not significant.

9.5.7.3.7 Trapping

9.5.7.3.7.1 Potential Effects

The Project footprint (including the road, aggregate pits, construction staging areas, and work camps) overlaps with seven trapline areas: GE138, GE148, GE153, GE154, GE157, GE159, and GE164. This section describes the changes to land that may be used for trapping activities within the above seven trapline tenures as a result of Project development. Following this, a description of how the Project could impact furbearing wildlife species populations, which could also have an impact on trapping activity, is presented.

Multiple attempts were made to contact trappers registered to each of these traplines through the Ministry of Natural Resources contact information. Letters were prepared and sent to the Ministry of Natural Resources for distribution to the trapline holders on record. No responses were received. Trapping related information was also acquired through the Indigenous Knowledge information that was requested from the communities to form the foundation for existing conditions including potential impacts to Aboriginal and / or Treaty Rights and Interests. At the time of drafting this assessment, Indigenous Knowledge was submitted by Marten Falls First Nation, Weenusk First Nation, Fort Albany First Nation, Aroland First Nation and Kashechewan First Nation which has been considered in this assessment, meaning that this information has been

included into the scientific data collected. It is understood that the holders of these traplines are all Indigenous people that live in either Marten Falls First Nation, Aroland First Nation, and / or other communities. Feedback from both Marten Falls First Nation and Aroland First Nation during the Community Information Centres was also utilized in this effects assessment.

As is the case for northern Ontario and much of Canada, trapping activity as a commercial activity has been greatly diminished over the last 20 years or so because of the low price of fur pelts. The prices narrowly covers the costs to undertake trapping (in other words, snowmobiling and fuel). Trapping does however, to some extent, still occur as a cultural activity for Indigenous people. Trapping impacts have also been assessed regarding potential impacts on Indigenous rights. Anecdotal information provided by community representatives at Project engagement events suggests that very limited trapping activity occurs now.

Below describes the loss of area from the Project for each affected trapline. In addition to the direct loss of lands that support furbearing species, disturbance effects from construction activities including the presence of humans and construction noise may result in some species moving from the adjacent lands. This disturbance would be a temporary effect but could still last up to ten years although the length of period for any one area of the Project would be much less given the sequencing of the construction.

Commercial trapping and snaring activities covered large geographic areas that extend approximately 30 km on either side of the Albany River and through the proposed Community Access Road route. Marten Falls First Nation identified 13 commercial harvesting sites which are used for trapping and snaring for commercial purposes.

GE138

GE138 covers an area of approximately 58,720 hectares. This trapline is transected by the following Project components: aggregate sites. More specifically, the Construction Disturbance Area overlaps 148.6 hectares of GE138, which is about 0.25 percent of the total trapline area. At the time of preparing this assessment no specific information from the trapline holder was available. It is not known whether trapping activity continues in this trapline or in the vicinity of the Project.

GE148

GE148 covers an area of approximately 858,208 hectares. This trapline is transected by the following Project components: access road, aggregate sites, camp, camp access road, and preferred route. More specifically, the Construction Disturbance Area overlaps 507.7 hectares of GE148, which is about 0.06 percent of the total trapline area. At the

time of preparing this assessment no specific information from the trapline holder was available. It is not known whether trapping activity continues in this trapline or in the vicinity of the Project.

GE153

GE153 covers an area of approximately 8,460,190 hectares. This trapline is transected by the following Project components: access road, aggregate sites, camp, camp access road, and preferred route. More specifically, the Construction Disturbance Area overlaps 1,036.1 hectares of GE153, which is about 0.01 percent of the total trapline area. At the time of preparing this assessment no specific information from the trapline holder was available. It is not known whether trapping activity continues in this trapline or in the vicinity of the Project.

GE154

GE154 covers an area of approximately 1,545,374 hectares. This trapline is transected by the following Project components: access road, aggregate sites, camp, camp access road, and preferred route. More specifically, the Construction Disturbance Area overlaps 630.4 hectares of GE154, which is about 0.04 percent of the total trapline area. At the time of preparing this assessment no specific information from the trapline holder was available. It is not known whether trapping activity continues in this trapline or in the vicinity of the Project.

GE157

GE157 covers an area of approximately 13,531,800 hectares. This trapline is transected by the following Project components: access road, aggregate sites, camp, camp access road, and preferred route. More specifically, the Construction Disturbance Area overlaps 1,921.3 hectares of GE157, which is about 0.01 percent of the total trapline area. At the time of preparing this assessment no specific information from the trapline holder was available. It is not known whether trapping activity continues in this trapline or in the vicinity of the Project.

GE159

GE159 covers an area of approximately 2,413,206 hectares. This trapline is transected by the following Project components: access road, aggregate sites, and preferred route. More specifically, the Construction Disturbance Area overlaps 203.8 hectares of GE159, which is about 0.008 percent of the total trapline area. At the time of preparing this assessment no specific information from the trapline holder was available. It is not known whether trapping activity continues in this trapline or in the vicinity of the Project.

GE164

GE164 covers an area of approximately 579,021 hectares. This trapline is transected by the following Project components: access road, aggregate sites, camp, camp access road, and preferred route. More specifically, the Construction Disturbance Area overlaps 252.3 hectares of GE164, which is about 0.044 percent of the total trapline area. At the time of preparing this assessment no specific information from the trapline holder was available. It is not known whether trapping activity continues in this trapline or in the vicinity of the Project.

Change in Environmental Conditions

Changes in environmental conditions, including noise and wildlife abundance distribution may cause indirect effects to trapping. Though trapping as a commercial activity has diminished in this area, changes to these conditions as outlined below could impact trapping activity that remains.

Noise

Noise could disturb trappers operating in the vicinity of the Project as well as furbearers resulting in less abundance close to the Project location. As documented in the Acoustic and Vibration Environment Technical Support Document (**Appendix P**) the magnitude of the noise net effects during construction were assessed to have the potential to range from low to high, depending on the distance between the points of reception and the construction activities. Daytime noise levels in proximity of the road from various aspects of construction are predicted to range from 38 to 84 A-weighted decibels. However, not all construction activities are expected to occur at the same time as modelled and therefore, in reality, noise levels should be lower. During operations, noise levels are to range from 38 to 53 A-weighted decibels. Note that with a background noise level of about 38 A-weighted decibels, noise levels of 45 A-weighted decibels or greater are considered to be noticeable.

Noise during construction is characterized as being local in nature, infrequent and temporary for any specific receptor point along the road. Noise in the vicinity of the aggregate pits may last longer depending on the size and life of the pit. All seven traplines intersecting the Construction Disturbance Area will experience short-term noise effects at infrequent levels during both construction and operations of the Project. The impact this noise might have on trapping is unknown. Trappers operating in the area may choose to conduct their activities further from the road because of increased noise levels.

Wolverine Abundance

Wolverine is a species that has been trapped in the Local and Regional Study Area. As reported in the Wildlife Technical Support Document (**Appendix K**), the magnitude of the predicted residual effects on wolverine are of moderate magnitude, permanent (irreversible) and vary from being confined to the effects assessment Construction Disturbance Area to the Wolverine effects assessment Local Study Area in geographic extent. It is expected that 4,700 hectares of wolverine habitat will be directly lost in the Construction Disturbance Area. Due to the high level of uncertainty related to how wolverines will respond once the Project is constructed, and the ability to avoid or mitigate effects on the regional population, effects to wolverine were assessed as significant. Considering the uncertainty of the assessment on the regional population impact on this species, the minimal commercial trapping currently occurring, the project's location on the edge of wolverine habitat, and anecdotal evidence suggesting that wolverines were not a major species trapped in the past, the resulting impacts on this valued component are considered to be low to moderate.

American Marten

American marten is a species that has been trapped in the Local Study Area. As reported in the Wildlife Technical Support Document (**Appendix K**), predicted residual effects on American martens are of negligible to low magnitude and are considered to be short-term to irreversible in duration. Most effects are considered to be limited to the Construction Disturbance Area, with increased access and sensory disturbance expected to extend into the Local Study Area. Overall, American marten populations are expected to remain ecologically functional and self-sustaining. The anticipated changes to American marten habitat availability, distribution, and survival and reproduction from the Project are expected to remain within the resilience and adaptability limits of the regional populations. As such, there is not expected to be a decrease in American marten populations to impact trapping activities.

Beaver

Beaver is the furbearer that has been historically trapped in the Local Study Area. As reported in the Wildlife Technical Support Document (**Appendix K**), overall, beaver populations are expected to remain ecologically functional and self-sustaining. The anticipated changes to beaver habitat availability, distribution, and survival and reproduction from the Project are expected to remain within the resilience and adaptability limits of the regional populations. As such, there is not expected to be a decrease in beaver populations to impact trapping activities.

As for all the furbearer species, increased trapping mortality may correspond to an increase in access to the lands along the corridor. This effect may be particularly strong in areas adjacent to good habitat. It is not possible to predict the impact that the increased access to the area might have on the populations of these species. Given that similar development in Northern Ontario has occurred as it relates to forestry operations and construction of roads, animal populations have been known to rebound once construction activities have been completed.

There are no anticipated effects on Gender-Based Analysis Plus sub-groups related to Trapping during construction or operations of the Community Access Road.

9.5.7.3.7.2 Mitigation and Enhancement Measures

Mitigation measures include providing notice to trapline tenure holders on the timeline and periods of construction and allow access through the Construction Disturbance Area (when it is safe to do so) as required for trapping activities throughout construction.

- Proposed mitigation to minimize effects as outlined in the Wildlife Technical Support Document (**Appendix K**), are as follows:
  - The possession and use of firearms will not be permitted for construction personnel;
  - Access to the Community Access Road corridor will be restricted during construction to workers only. Temporary access roads should be restricted during use and restored as soon as possible after they are no longer needed. Permanent access roads used for maintenance activities will be blocked while not in use;
  - Temporary access roads and other temporary construction infrastructure will be reclaimed as quickly as possible following construction. As part of the reclamation of temporary access roads, access to these roads will be physically blocked to decrease public use. Access roads used for permanent maintenance activities will be blocked while not in use;
  - Beaver lodges will be marked as sensitive sites and protected. A figure illustrating that location where beaver lodges were observed during existing conditions field surveys will be included in the Environmental Protection Plan. The Environmental Protection Plan will outline appropriate setbacks and procedures to be followed when beaver lodges are encountered during construction;
  - An Environmental Protection Plan will be implemented that includes the following measures to control, and / or restrict public use of access roads during construction and operation: speed limits, signage, reduced road

standard, felling of timber across temporary access roads after reclaimed, removal of temporary watercourse crossings, reduce traffic by locating camps near construction sites. Posting of restricted access and speed signage will follow the Construction Specification for Temporary Traffic Control Devices (Construction Specification for Temporary Traffic Control Devices, 2016);

9.5.7.3.7.3 Predicted Residual Effects

The Project Construction Disturbance Area intersects a very small proportion of each affected trapline area (less than 0.5 percent), resulting in a low magnitude adverse residual effect related to direct land occupation. The geographic extent of direct effects is localized to the road corridor, aggregate pits, and associated Project components, with the majority of each trapline remaining available for trapping activities.

Changes to access conditions represent a long-term effect associated with the operational phase of the Project and may influence trapping practices by increasing the presence of other land users along the corridor. While improved access may reduce travel time for trapline holders, it may also increase competition or disturbance in areas adjacent to the road. The magnitude of these access-related effects is assessed as low given the limited width of the corridor and the continued availability of extensive undisturbed areas within each trapline. The extent to which access-related effects materialize is dependent on future access management, enforcement, and user behaviour, introducing a degree of uncertainty in effect prediction.

Construction-related noise and activity may temporarily displace furbearing species and disrupt trapping activities in proximity to active work areas. These effects are assessed as low to moderate in magnitude, localized in extent, and short-term and reversible, as construction progresses sequentially along the corridor.

Potential effects on furbearer populations relevant to trapping vary by species. Residual effects on American marten and beaver populations are assessed as low in magnitude, with populations expected to remain self-sustaining and ecologically functional. In contrast, residual effects on wolverine were assessed as moderate in magnitude, permanent, and significant in the wildlife valued component due to habitat loss and uncertainty in population response. While wolverine trapping is understood to be limited in the Project area, uncertainty regarding population-level responses introduces a moderate level of risk to trapping opportunities associated with this species.

The combination of localized habitat loss, sensory disturbance, and increased access may contribute to incremental pressure on trapping activities within portions of the affected traplines. However, considering the small proportion of trapline areas directly affected, the localized nature of effects, the continued availability of extensive trapping

lands, and the limited current level of commercial trapping activity, the overall magnitude of cumulative adverse effects on trapping is assessed as moderate.

Recognizing the absence of trapper-specific information for several intersected traplines and the uncertainty associated with access-related effects and furbearer population responses, residual effects on trapping are characterized with moderate uncertainty. Continued engagement with trapline holders and follow-up monitoring would assist in refining the understanding of long-term effects.

Taking into account the magnitude, geographic extent, duration, reversibility, and uncertainty of effects, adverse residual effects on the trapping valued component are assessed as not significant at the local and regional scale. Also please refer to the Aboriginal and / or Treaty Rights and Interests Technical Support Document (**Appendix O**) regarding the impact of the Project on trapping in relation to Aboriginal rights.

9.5.7.3.8 Energy and Linear Infrastructure

9.5.7.3.8.1 Potential Effects

Energy and linear infrastructure refer to electricity infrastructure (such as generation stations, hydro-electric infrastructure, and transmission lines) and natural gas infrastructure (such as pipelines and extraction sites). At the time of writing this Report, there are no existing energy or linear infrastructure facilities or projects in development in the Construction Disturbance Area.

The Project will not result in the direct removal, relocation, or modification of existing energy or linear infrastructure.

9.5.7.3.8.2 Mitigation and Enhancement Measures

No project-specific mitigation measures are required for this valued component, as the Project does not directly involve the construction or modification of energy or linear infrastructure.

Coordination and information sharing between the province, the road owner, and relevant utility proponents may occur as part of future planning initiatives. Any proposed energy or linear infrastructure projects that utilize the Community Access Road corridor would be required to undergo separate environmental assessment and permitting processes, including the identification of project-specific mitigation and enhancement measures.

9.5.7.3.8.3 Predicted Residual Effects

The Project will not result in adverse residual effects on existing energy or linear infrastructure, as none currently occur within the Construction Disturbance Area. The establishment of the Community Access Road may create a long-term, indirect beneficial effect by increasing access and opportunity for future energy and linear infrastructure development.

9.5.7.4 Residual Effects – Operations Phase

9.5.7.4.1 Land Use Compatibility

9.5.7.4.1.1 Potential Effects

Portions of the Preferred Route fall within lands that are managed by the Ministry of Natural Resources under Crown land management direction for Geraldton Area (general use area) through the Crown Land Use Policy Atlas. The Crown Land Use Policy Atlas provides policy direction for Crown Land use and in this area identifies permitted uses, including road development and aggregate extraction, subject to applicable approvals and permitting requirements. Existing land uses such as commercial outpost camps are administered under the *Public Lands Act*. As such, the types of infrastructure associated with the Community Access Road are consistent with existing Crown land use policy direction applicable to the area.

The majority of the Preferred Route falls within the Far North. In accordance with Section 14 of the *Far North Act*, existing rights for the acquisition, disposition, use or occupancy of public lands and activities associated with these uses (such. commercial outpost camps) remain valid where they were established prior to the finalization of a community-based land use plan. As such, no land use compatibility associated with the Far North or *Public Lands Act* will have potential effects.

9.5.7.4.1.2 Mitigation and Enhancement Measures

Please refer to mitigation measures during construction.

9.5.7.4.1.3 Predicted Residual Effects

Effects are local in geographic extent, and operational impacts will persist for the duration of the project as long as the road remains in use. The effect is indirect, irreversible, and certain to occur.

9.5.7.4.2 Ontario Parks and Protected Areas

9.5.7.4.2.1 Potential Effects

The Albany River Provincial Park is recognized for its 'wilderness and remote character' and is valued for remote backcountry wilderness experiences. The road crossing through the Albany River Provincial Park (approximately 0.6 kilometres in length) and the presence of a bridge will introduce a localized visual feature, with the bridge visible approximately 900 metres upstream and 700 metres downstream as identified in the Visual Environment Technical Support Document (Appendix V).

Park users in proximity to the bridge may experience intermittent noise from vehicle traffic during Operations. Noise levels may exceed 35 A-weighted decibels within 1 km of the Albany River bridge location. Noise levels would be higher closer to the bridge crossing location. Baseline noise levels are about 35 to 40 A-weighted decibels and levels over 5 A-weighted decibels are noticeable. Noise effects will be intermittent and dependent on vehicle presence.

Fugitive dust from the unpaved road may affect areas within 3 kilometres of the crossing under maximum traffic conditions modeled for 2046 (**Appendix S**) this level of traffic is not anticipated but was used to provide an uppermost limit for the impacts being considered. Given the remote setting and anticipated low traffic volumes, these effects are expected to be infrequent and short in duration.

Ogoki River Provincial Park, Little Current River Provincial Park, Otoskwin–Attawapiskat River Provincial Park, Nakina Moraine Provincial Park, and Jobes Creek Area of Natural and Scientific Interest are not expected to experience operational noise or air quality effects due to distance from the road. A possible indirect effect related to this indicator is the potential for reduced Park users because of disturbance effects from road operations (for example, noise) and change in the wilderness character of the area from visibility of the bridge crossing (for the Albany River Park). The disturbance effects to the three parks noted above will be limited in area / localized and as a result, adverse impacts to park user volumes are not expected to be materially affected.

Once operational and if open for public use, the new road would provide a new access point to Albany River Provincial Park. Improved access could increase recreational use and support new canoe trip options. Any changes to access would be subject to Ontario Parks review and may require updates to the Albany River Provincial Park Management Statement. Public access would not be available during construction.

Improved access to the Ogoki River may also increase use of Ogoki River Provincial Park. Given the continued remoteness of the area, increases in user volumes are

anticipated to be limited. No changes in access are expected for Little Current River Provincial Park or other more distant protected areas.

There would be indirect effects as it relates to Operation, with improved access to the Albany River and Ogoki River Provincial Parks and possible increase in user volumes, this could detract from the wilderness character of these parks. Given the long driving distance still required to reach these parks, it is anticipated that user volumes would increase slightly as a result of introduced access.

Though no information or data is available related to the vulnerable groups for the Land and Resource Use Discipline, women / girls may feel unsafe or at-risk during construction of the Community Access Road should they be accessing the Albany River Provincial Park during that time. It is highly unlikely that youth will be accessing such a remote area unsupervised. There are no anticipated effects on Gender-Based Analysis Plus sub-groups related to Parks and Protected Areas during operations.

9.5.7.4.2.2 Mitigation and Enhancement Measures

Mitigation and enhancement measures to be implemented during operations include:

- Any potential access considerations will be explored further through ongoing consultation with Ontario Parks so that future decisions align with park management objectives and protection priorities.
- Refer to mitigations as outlined in the Atmospheric Environment Technical Support Document (**Appendix S**);
- Monitor and limit the development of any side trails / roads that might extend into parks; and
- The Owner of the road to continue to monitor and enforce (if deemed necessary) restricted access to Albany River Provincial Park at the bridge crossing to address access issues and user impacts.
- During maintenance works, the owner of the road should notify Ontario Parks of upcoming rehabilitation associated with the bridge to allow Ontario Parks to notify future Parks users.

9.5.7.4.2.3 Predicted Residual Effects

Improved access to Albany River and Ogoki River Provincial Parks represents a potential positive effect by increasing opportunities for recreational access in remote areas.

While increased access to Albany River Provincial Park could result in higher user volumes, the realization and magnitude of such effects would depend on road access

controls, traffic volumes, and Ontario Parks' management decisions. Given the continued remoteness of the area and existing Ontario Parks management authorities, a substantial increase in recreational use is not considered reasonably foreseeable at this time.

Considering the ecological and social context, magnitude, geographic extent, duration, and reversibility of effects, adverse residual effects on Parks and Protected Areas are assessed as not significant.

9.5.7.4.3 Recreation and Tourism

9.5.7.4.3.1 Potential Effects

The operation of the Project could result in disruption effects and enjoyment to recreation and tourism activities (for example, disturbances from changes in noise, vibration, air quality, and viewscapes). Recreation features in the Local Study Area include water access recreation such as canoeing and boating.

Due to the remote nature of the Project Local Study Area and limited existing access, recreational use outside provincial parks and remote outfitter areas is understood to be limited. While noise and air quality changes will occur in close proximity to the road and ancillary facilities (aggregate pits) during operations effects on recreational use are assessed as localized, intermittent, and low in magnitude for both construction and operation due to the low number of visitors.

Air quality effects during operations were assessed using conservative upper-bound traffic scenarios; given the remote setting and anticipated low traffic volumes, effects on recreational users are expected to be infrequent and short in duration.

The operation of the Project could influence the availability of species harvested for recreational purposes through localized habitat removal and changes in access to lands and waterways used for hunting and fishing. Habitat removal associated with the Project is expected to be limited in extent and localized to the Construction Disturbance Area.

Improved access resulting from the Project could increase recreational hunting and fishing opportunities in the vicinity of the road. From a recreation and tourism perspective, effects are expected to be related primarily to changes in access and user distribution rather than Project-related changes in overall species abundance.

Potential effects related to wildlife habitat, species abundance, population dynamics, and sustainability are assessed under the wildlife, ungulates, and fish valued components. Wildlife and fish populations are managed through existing provincial programs administered by the Ministry of Natural Resources.

9.5.7.4.3.2 Mitigation and Enhancement Measures

Mitigation measures related to fish and fish habitat and wildlife originate from the Fish and Fish Habitat Technical Support Document (**Appendix G**) and Ungulates Technical Support Document (**Appendix M**) and are addressed under those valued components. Additional mitigation and monitoring related to wildlife populations, hunting pressure, and fish harvest will continue to be managed through existing provincial programs.

Vegetation clearing limits, buffer zones, and erosion and sediment control measures associated with waterbodies will be implemented in accordance with Project design requirements and applicable regulatory approvals.

9.5.7.4.3.3 Predicted Residual Effects

Noise effects during operations is low in magnitude and localized in nature (close to the road and the few aggregate pits that would remain open). No recreation receptor locations were identified. These effects are considered not to be significant. For more details on noise, see Acoustic and Vibration Environment Technical Support Document (Appendix S).

Improved access may provide new recreational opportunities; however, the magnitude of change in recreational use will depend on future access controls and management decisions. Given the continued remoteness of the area and existing regulatory oversight, substantial changes to recreation and tourism patterns are not considered reasonably foreseeable.

As a result, adverse residual effects on Recreation and Tourism are assessed as not significant.

9.5.7.4.4 Extractive Resource Industry

9.5.7.4.4.1 Potential Effects

The operation of the road could have an **indirect effect** of improving access to mineral resource areas and facilitate the development of mines that would provide jobs and economic benefit to the region and local communities. Mining claim holders spoken to indicate support for the Project for this reason. As such, the Project is anticipated to result in a moderate to high benefit to mine development in the Local Study Area and Regional Study Area, specifically as it relates to a deposit in the Ring of Fire area.

There are positive beneficial effects on Gender-Based Analysis Plus sub-groups related to the Extractive Resource Industry as this could create future employment and other infrastructure opportunities for the surrounding Indigenous Communities for the operation of the Community Access Road that will lead to a future Mine.

9.5.7.4.4.2 Mitigation and Enhancement Measures

Mitigation and enhancement measures for the extractive resource industry include engaging with mining claim holders in the road design stage to determine how impacts to any mineral deposits can be minimized and / or how the Project can help to support their activities.

9.5.7.4.4.3 Predicted Residual Effects

Improved access resulting from the Project represents a beneficial effect for the extractive resource industry by facilitating future exploration and development opportunities; however, the realization of these benefits would depend on separate project proposals, regulatory approvals, and market conditions.

Considering the limited spatial extent of overlap, the absence of identified constraints on mineral development, and the increased accessibility to claim areas, adverse residual effects on the Extractive Resource Industry are assessed as not significant.

9.5.7.4.5 Forestry Industry

9.5.7.4.5.1 Potential Effects

Due to the lack of actively harvested forestry lands within the Construction Disturbance Area outside of the Ogoki Forest, the Project will have minimal adverse direct or indirect effects to this valued component. Forestry companies were advised of the Preferred Route in Fall 2024 and Spring 2025 with a request for comments. No comments were received regarding the Preferred Route or comments from review of the Draft Environmental Assessment / Impact Statement.

9.5.7.4.5.2 Mitigation and Enhancement Measures

Please refer to mitigation measures during construction.

9.5.7.4.5.3 Predicted Residual Effects

Adverse residual effects on the Forestry Industry are not expected, as the Construction Disturbance Area overlaps approximately 0.24 percent of the Ogoki Forest, representing a negligible to low magnitude effect relative to the overall forest management unit. Any merchantable timber removed for the Project will be managed and compensated in accordance with applicable Crown forest management requirements.

Given the limited spatial extent of overlap, the short duration of clearing activities, and the capacity of existing forest management and compensation frameworks to address localized timber removal.

9.5.7.4.6 Remote Outfitters

9.5.7.4.6.1 Potential Effects

There are two types of Land Use Permits issued by the Government of Ontario: those for restricted (Type B) outpost camps (in other words, short term seasonal use; limited infrastructure) and Type A commercial outpost camps (in other words, long term use year after year; permanent infrastructure). Though the Construction Disturbance Area does not directly overlap any remote outfitter camps, changes to the land resulting from both construction and operation of the Project may result in less people using these services. There were no restricted (type B) Land Use Permits identified in the Construction Disturbance Area, given that these types of Land Use Permits are set up in the same areas annually, it is not anticipated that these would be impacted. Unless explicitly noted in the Land Use Permit's Standard Conditions, restricted Land Use Permits expire after hunting seasons close for that year. Remote outfitters are then responsible for reapplication. Given that there were none identified, there would be no impact to these types of Land Use Permits.

Changes in environmental conditions, including air quality, noise, visual, surface water, fish abundance / distribution, wildlife abundance distribution, as well as a change in access may cause indirect effects to remote outfitters. Changes related to environmental conditions may change the attractiveness of these camps to their client base. The following describes changes in environmental conditions in the vicinity of the noted camps.

9.5.7.4.6.2 Mitigation and Enhancement Measures

During operations, if the Community Access Road will be considered public, access roads for aggregate areas and other infrastructure required for maintenance activities will be gated to limit public access. Employees will be prohibited from hunting or carrying firearms while working on the Project maintenance.

9.5.7.4.6.3 Predicted Residual Effects

Adverse residual effects are anticipated for remote outfitting operations at Painter Lake, Caviar Lake, and Teabeau Lake as a result of increased access to the area, development of aggregate pits, and Project-related noise, particularly during construction. These effects are associated primarily with changes in access conditions and a localized reduction in wilderness character, which may influence the user experience for clients seeking fly-in, remote outfitting opportunities.

Changes in access may result in increased presence of other land users in the area, which could further influence wilderness character and outfitter client experience. However, these effects are dependent on future access management decisions and user behaviour and are not expected to result in the displacement or closure of outfitting operations.

Effects related to the availability of species harvested for recreational hunting and fishing are not anticipated to be severe. Residual effects on fish and fish habitat were assessed as negligible to medium in magnitude and not significant in the fish and fish habitat valued component. Residual effects on moose and moose habitat were assessed as low to medium in magnitude, ranging from localized to regional in geographic extent, with populations expected to remain self-sustaining and ecologically effective. As such, effects on wildlife and fish availability relevant to outfitting operations are not expected to represent a substantial management concern.

Remote outfitting camps operate under Land Use Permits, which represent a limited tenure on Crown land. While this does not diminish the importance of outfitting operations, it indicates an existing level of exposure to changes in land use conditions. Camp operators will be provided with advance notice of construction activities (minimum one year), allowing for operational planning and adaptation. In addition, improved access may create opportunities for some operators to adjust service models (for example, drive-in or boat-access camps), partially offsetting adverse effects related to remoteness.

Considering the magnitude, duration, geographic extent, reversibility, and the capacity of outfitting operations to adapt, adverse residual effects on the remote outfitters valued component are assessed as not significant.

9.5.7.4.7 Trapping

9.5.7.4.7.1 Potential Effects

The Project footprint (including the road, aggregate pits, construction staging areas, and work camps) overlaps with seven trapline areas: GE138, GE148, GE153, GE154, GE157, GE159, and GE164.

9.5.7.4.7.2 Mitigation and Enhancement Measures

- During operations, if trappers have set up traps close to the corridor, signage will be in place to warn the travelling public and road maintenance staff of set traps in the area; and,
- During operations, if the Community Access Road will be public, access roads for aggregate areas and other infrastructure required for maintenance activities will be gated to limit public access. Employees will be prohibited from hunting or carrying firearms while working on the Project maintenance.

9.5.7.4.7.3 Predicted Residual Effects

The Project Construction Disturbance Area intersects a very small proportion of each affected trapline area (less than 0.5 percent), resulting in a low magnitude adverse residual effect related to direct land occupation. The geographic extent of direct effects is localized to the road corridor, aggregate pits, and associated Project components, with the majority of each trapline remaining available for trapping activities.

Changes to access conditions represent a long-term effect associated with the operational phase of the Project and may influence trapping practices by increasing the presence of other land users along the corridor. While improved access may reduce travel time for trapline holders, it may also increase competition or disturbance in areas adjacent to the road. The magnitude of these access-related effects is assessed as low given the limited width of the corridor and the continued availability of extensive undisturbed areas within each trapline. The extent to which access-related effects materialize is dependent on future access management, enforcement, and user behaviour, introducing a degree of uncertainty in effect prediction.

Noise effects during operations are expected to be intermittent and low in magnitude, occurring primarily during vehicle passage.

Potential effects on furbearer populations relevant to trapping vary by species. Residual effects on American marten and beaver populations are assessed as low in magnitude, with populations expected to remain self-sustaining and ecologically functional. In contrast, residual effects on wolverine were assessed as moderate in magnitude, permanent, and significant in the wildlife valued component due to habitat loss and uncertainty in population response. While wolverine trapping is understood to be limited in the Project area, uncertainty regarding population-level responses introduces a moderate level of risk to trapping opportunities associated with this species.

The combination of localized habitat loss, sensory disturbance, and increased access may contribute to incremental pressure on trapping activities within portions of the affected traplines. However, considering the small proportion of trapline areas directly affected, the localized nature of effects, the continued availability of extensive trapping lands, and the limited current level of commercial trapping activity, the overall magnitude of cumulative adverse effects on trapping is assessed as moderate.

Recognizing the absence of trapper-specific information for several intersected traplines and the uncertainty associated with access-related effects and furbearer population responses, residual effects on trapping are characterized with moderate uncertainty. Continued engagement with trapline holders and follow-up monitoring would assist in refining the understanding of long-term effects.

Taking into account the magnitude, geographic extent, duration, reversibility, and uncertainty of effects, adverse residual effects on the trapping valued component are assessed as not significant at the local and regional scale. Also please refer to the Aboriginal and / or Treaty Rights and Interests Technical Support Document (**Appendix O**) regarding the impact of the Project on trapping in relation to Aboriginal rights.

9.5.7.4.8 Energy and Linear Infrastructure

9.5.7.4.8.1 Potential Effects

At the time of writing this Report, there are no existing energy or linear infrastructure facilities or projects in development in the Construction Disturbance Area.

The Project will not result in the direct removal, relocation, or modification of existing energy or linear infrastructure. However, during operations, the establishment of a permanent road corridor may create increased opportunity for future energy and linear infrastructure development by improving access to a previously remote area. In Ontario, linear infrastructure such as transmission lines commonly follows existing transportation corridors for construction, access, and maintenance efficiency.

9.5.7.4.8.2 Mitigation and Enhancement Measures

No project-specific mitigation measures are required for this valued component, as the Project does not directly involve the construction or modification of energy or linear infrastructure.

9.5.7.4.8.3 Predicted Residual Effects

The Project will not result in adverse residual effects on existing energy or linear infrastructure, as none currently occur within the Construction Disturbance Area. The establishment of the Community Access Road may create a long-term, indirect beneficial effect by increasing access and opportunity for future energy and linear infrastructure development.

9.5.7.5 Summary of Residual Effects

Table 9.5-37 provides a summary of the potential effects for land and resource use, mitigation measures, and residual effects. Detailed information is included in **Appendix U**.

Table 9.5-37: Summary of Residual Effects for Land and Resource Use and Characterization

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Land Use Compatibility**	• Construction	• Due to the absence of land use planning policies for the Construction Disturbance Area and given the Marten Falls First Nation Draft Community-Based Draft Community-Based Land Use Plan is not in place, no adverse effects to this valued component are expected. • There are no indirect effects identified for this valued component for Construction. • There are no anticipated effects on Gender-Based Analysis Plus sub-groups related to Land Use Compatibility during construction or Operations of the Community Access Road.	• It is understood that Marten Falls First Nation will continue to work through the Draft Community-Based Land Use Plan to identify Dedicated Protected Areas. It is anticipated that some of the lands adjacent to the Project will be included as part of the Dedicated Protected Area to control development. The Dedicated Protected Area provides protection of watercourses, areas of significance, and other values including remote tourism camps, canoe routes, and trap cabins. • Lands for the proposed route require to be withdrawn from mining rights to secure the development of the road. • It is recommended that Marten Falls First Nation, the owner of the road and the province be involved in land and resource use planning activities to manage new development that may occur as a result of the Project. Marten Falls First Nation will also continue to update their Draft Community-Based Land Use Plan as necessary. • Aroland First Nation may advise on additional measures related to this valued component which is subject to ongoing engagement with them.	• No predicted residual effect. The Project is following land use intent and management direction with existing *Public Lands Act* and *Far North Act* requirements. Through discussion with Ontario Parks, it is understood that the crossing of the Albany River Provincial Park may require an amendment to the Park management plan which Ontario Parks will oversee if deemed required.	• Not Applicable
• **Land Use Compatibility**	• Operations	• The owner would be responsible for the continued operation and maintenance of the Community Access Road. The jurisdiction of the road would fall under the Public Transportation and Highway Improvement Act.	• All maintenance and operation works performed on the Community Access Road must follow provincial standards and specifications for road and water crossing rehabilitation. • All maintenance and operation works must also comply with all environmental legislation.	• Residual effects from operations to continue throughout the lifespan of the Community Access Road.	• Context: Social • Direction: Positive • Magnitude: Low • Geographic Extent: Local • Duration: Long-term • Frequency: Regular rehabilitation every 5-10 years with minor maintenance required sporadically. • Reversibility: Irreversible • Likelihood: Certain. • Direct / Indirect: Indirect • Significance: Not Significant • Confidence: High • Direct / Indirect: Indirect

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Parks and Protected Areas**	• Construction	• The Project Construction Disturbance Area crosses through the Albany River Provincial Park. The Construction Disturbance Area transects with 5.7 hectares of Park land, which would require vegetation removal during construction. A new bridge would be constructed in the Park to cross the river for 0.6 kilometres. While this will be a direct adverse effect, it represents a very small portion of the Park which is about 0.006 percent of the total area of Albany River Provincial Park of the total size of 95,100 hectares. This effect is considered to be minor in magnitude. • During bridge construction, Albany River Provincial Park may experience up to 70 A-weighted decibels at the bridge crossing location, dropping to 30 A-weighted decibels 5 kilometres away for a minimum of two years. Albany River Provincial Park users may also experience noise from aggregate extraction at pits located on the south side of the Park just west of the proposed crossing location. • Only a very limited amount of the most eastern end of the Ogoki River Park (about 500 metres in) would experience noise effects greater than 45 A-weighted decibels, which is considered to be a noticeable change over existing conditions.	• Refer to mitigations as outlined in the Atmospheric Environment Technical Support Document (**Appendix S**). • Limit clearing and use of land within the Parks as much as possible. Temporary work areas such as staging areas should be located outside of park boundaries. • Monitor and limit the development of any side trails / roads that might extend into the park boundaries. Marten Falls First Nation to discuss with Ontario Parks the need for measures to control access into parks and protected areas where applicable.	• Residual changes from the Construction to the Albany River Provincial Park and Ogoki River Provincial Park.	• Context: Ecological, Social • Direction: Adverse • Magnitude: Low • Geographic Extent: Local and primarily in the vicinity of the river crossing location. • Duration: Short-term • Frequency: Continuous • Reversibility: Reversible • Likelihood: High certainty. • Significance: Not Significant • Confidence: High • Direct / Indirect: Direct
• **Parks and Protected Areas**	• Operations	• Albany River Provincial Park is recognized for its ‘wilderness and remote character’ and is valued for remote backcountry wilderness experiences. The road crossing of the Albany River Provincial Park, a distance of 0.6 kilometres, could contribute to a reduction of the remote character of the Park and impact park user enjoyment levels. The presence of a new bridge across the river would result in a visual impact with the bridge being visible about 900 metres upstream and 700 metres downstream. • There is also potential for some noise and air quality effects on park users from passing vehicles. These effects would be directly related to traffic volume on the road. During the operations phase, users of Albany River Provincial Park may experience >35 A-weighted decibels within 1 kilometres of the bridge location. Noise levels would be higher closer to the bridge crossing location. Baseline noise levels are about 35 to 40 A-weighted decibels and levels over 5 A-	• Refer to mitigations as outlined in the Atmospheric Environment Technical Support Document (**Appendix S**). • Monitor and limit the development of any side trails / roads that might extend into parks. • Continued engagement with Ontario Parks on the progress of the road design and advance notice of construction should be provided to give park users ample notice of proposed construction or maintenance occurring near the parks. • Marten Falls First Nation and the owner of the road to have further discussions with Ontario Parks regarding the Albany River crossing (bridge design), access issues, and user impacts as well as need for updates to the Ogoki and Albany River Provincial Parks. • Any potential access considerations will be explored further through ongoing consultation with Ontario Parks so that future decisions align with park management objectives and protection priorities.	• Residual changes from the Operations to the Albany River Provincial Park and Ogoki River Provincial Park.	• Context: Ecological, Social • Direction: Adverse and potentially positive from new Parks access opportunities. • Magnitude: Low • Geographic Extent: Local • Duration: Long-term • Frequency: Frequent • Reversibility: Yes (for traffic noise). Potential Park access restrictions if put in place would limit or reduce impacts from potentially higher user volumes. • Likelihood: Certain • Significance: Not significant • Confidence: High • Direct / Indirect: Direct

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
		weighted decibels are considered to be noticeable. As noise levels are tied to road use, Park users detecting increased noise would depend on whether a vehicle is traveling along the road when a Park user is in the vicinity of the bridge (for example, travelling down the river by canoe). • Once operational and open to public use, the new road could provide a new access point to the Parks it intersects with. Subject to Ontario Parks support, new access opportunities could be created for the Albany River Provincial Park. This would be beneficial potentially leading to more park users and by providing a new end point or start point for river trips. • While the road does not cross Ogoki River Provincial Park, the road will cross the Ogoki River just to the east of the Park and could also improve access to the river and provide new access to this park (by boat / canoe). Again, this is subject to Ontario Parks support. • As with the Albany River Provincial Park, the improved access from the road might result in more use of the Ogoki River Provincial Park.			
• **Recreation and Tourism**	• Construction	• While limited recreation occurs in the area due to its remote / inaccessible nature, the construction of the Project could result in disruption effects to recreation and tourism activities (for example, disturbances from changes in noise, vibration, air quality, and viewscapes). • The new watercourse crossings could potentially affect navigation (for safety purposes) during construction of the Project. Structures will be designed to permit navigation on waterways deemed to be navigable. • Overall moose health and population abundance is not expected to decrease as a result of habitat loss. • Northern pike, brook trout, walleye, and lake whitefish / burbot populations may all experience effects in the local area, particularly during construction from loss of habitat (bridge construction) and saltation effects. Overall long-term population abundance effects are not expected.	• Design and install proper water crossing structures to accommodate flow, drainage, fish passage, and navigation. • Minimize vegetation clearing to only what is required for construction and staging. • Provide signage along the Preferred Route to inform road users about possible interaction with recreation users, wildlife and restrictions. • The Proponent will discuss possible restrictions for hunting in the Project Area with the Ministry of Natural Resources. • Assess need for parking control along road for safety reasons.	• Residual changs to access to commercial outpost camps, guided fishing and hunting activity along the Albany River.	• Context: Ecological, Social • Direction: Adverse • Magnitude: Low • Geographic Extent: Local • Duration: Long-term • Frequency: Continuous during the construction period • Reversibility: Reversible / irreversible • Likelihood: High certainty • Significance: Not significant • Confidence: High • Direct / Indirect: Direct

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Recreation and Tourism**	• Operations	• The operation of the Project could result in disruption effects to recreation and tourism activities (for example, disturbances from changes in noise, vibration, air quality, and viewscapes). • The future road, which will be approximately 184 kilometres in length, is anticipated to improve access levels to remote crown lands and water resources (assumed that the road would be open to the public during operations). This could provide new recreation and tourism opportunities including: camping, snowmobiling, hunting, fishing, and canoe / kayaking. This would be a beneficial effect of the Project. Note that some of these recreation benefits would not occur if access restrictions to the public (for example, no hunting) are imposed because of law and local Indigenous community concerns. • Though moose health is not expected to be affected and population is not expected to decrease in abundance, there are concerns that with increased access to the area that there could be an increase in illegal hunting / poaching, which could adversely affect moose populations over time. It is also considered that the road could cause wildlife mortality. • Further, from increased access, there could be increased fishing pressure on the waterways in proximity to the road which could also adversely impact species abundance. However, fish populations are expected to be self-sustaining and ecologically effective.	• Design and install proper water crossing structures to accommodate flow, drainage, fish passage and navigation. • Minimize vegetation clearing to only what is required for construction and staging. • Implement progressive reclamation and revegetation of disturbed areas no longer required following construction (laydown areas and construction camps). • Consider provide signage along the Preferred Route to inform road users about possible interaction with recreation users and wildlife. • Consider installation of Crimestoppers signage that discourages poaching and provides the public with a number to call if witnessing poaching or illegal hunting. • Assess need for parking control along right-of-way shoulder for safety reasons. • A cleared width of 60 metres will be maintained, buffer zones of 30 metres will be maintained around waterbodies, and vegetation clearing activities will be limited. • Consider engagement with Ministry of Natural Resources to discuss data collection related to fish through broadscale monitoring or creel surveys to monitor populations.	• Residual changs to access to commercial outpost camps, guided fishing and hunting activity along the Albany River.	• Context: Ecological, Social • Direction: Adverse to positive. • Magnitude: Low to moderate • Geographic Extent: Local • Duration: Long-term • Frequency: Continuous • Reversibility: Reversible, for traffic noise and for access-related impacts through resource road safety requirements and resource management activities (aggregate extraction) activities. • Likelihood: Certain • Significance: Not significant • Confidence: High • Direct / Indirect: Direct
• **Extractive Resource Industry**	• Construction • Operations	• Within the Construction Disturbance Area there are 2,234 hectares of active mining claims, which could be affected by the road and associated Project components. Two mining claim holders will be affected by the development of the road: Wabassi Resources and Canada Chrome Corporation. • It is noted that an aggregate pit is located on the site of an existing Wabassi exploration camp. It is not known how long this exploration camp is to operate. Further consultation are required with Wabassi to better understand this camp and potential impacts to it as a result of the Project. • The development of the road could have an indirect effect of improving access to mineral resource areas and facilitate the development of mines that would provide jobs and economic benefit to the region and local communities.	• Mining companies have indicated their support of the Project due to the increased accessibility that would result to the existing mining claims. • Mitigation and enhancement measures for the extractive resource industry include engaging with mine claim holders in the road detail design stage to determine how impacts to any mineral deposits can be minimized and / or how the Project can help to support their activities. • The owner of the road will consider future mining equipment vehicles use of the road in order to design and maintain to a specific standard to accommodate heavy machinery or excessive number of vehicles.	• Residual effects to access for mining camps and mining claim holders.	• Context: Ecological, Social • Direction: Positive • Magnitude: Moderate • Geographic Extent: Local / Regional • Duration: Long-term • Frequency: Continuous • Reversibility: Reversible • Likelihood: Moderate • Significance: Not significant • Confidence: High • Direct / Indirect: Direct

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Forestry Industry**	• Construction • Operations	• The Ogoki Forest is approximately 1,087,986 974,100 hectares in size. The Construction Disturbance Area intersects 4,700.2384.4 hectares of the Ogoki Forest (bog, forest, marsh, swamp, water, rock, fen, and anthropogenic). Of that, 2,311.7195.4 hectares of forest (coniferous, deciduous, early successional / sparse treed, and mixed) would be removed. At the time of writing, the Ogoki Forest is not actively harvested nor are we aware of any plans for harvesting. There is the potential for direct effects on the Ogoki Forest via removal of commercial forestry land, however, given the percentage of total area of the area affected (0.24 percent of the total area of the Ogoki Forest) this effect is expected to be negligible. There are anticipated harvesting activities as part of the Forest Management Plan (2020-2030). Continuous engagement with the Sustain Forest Licence holder is suggested to determine future harvesting activities that are occurring in the Construction Disturbance Area. • Upgrades to the Painter Lake Road through this Project will assist in harvesting activities that occur from secondary and tertiary forestry roads in this area.	• Should any merchantable forest trees be felled within the Ogoki Forest Management area for Construction, the value of the timber will be determined. • Should any merchantable timber be felled within the Ogoki Forest Management area for the construction of the Project, the value of the timber will be determined. • Review of the Ogoki Annual Work Schedule for harvesting and silvicultural operations should continue throughout detail design if trees are required to be harvested for the construction of the road. • Continued consultation with the Forestry Company regarding road upgrades or planned construction should occur to not disrupt harvesting or silvicultural activities	• Residual changes to Ogoki • Adverse residual effects are not expected as the Construction Disturbance Area overlaps only 0.24 percent of the Ogoki Forest and should any merchantable timber be removed for the Project, applicable compensation will be provided for the loss of those trees.	• Context: Ecological • Direction: Adverse • Magnitude: Low • Geography Extent: Local • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Certain • Significance: Not significant • Confidence: High • Direct / Indirect: Direct
• **Remote Outfitters**	• Construction	• Painter Lake commercial outpost camps and the Caviar Lake commercial outpost camp are likely to experience the highest impact from noise during construction. • Painter Lake and Caviar Lake are likely to experience the highest visual impact during construction. • Northern pike, brook trout, and walleye may all experience effects, particularly during construction from loss of habitat (bridge construction) and sedimentation saltation effects. Fish populations are expected to be self-sustaining and ecologically effective. • Moose health is not expected to be affected and population is not expected to decrease in abundance as a result of project development. If moose populations do change through monitoring by the Ministry of Natural Resources, tag allocations to outfitters could be impacted.	• Engage further with the impacted outfitters / camp owners. A letter was sent in Fall 2024 to known trappers via the Ministry of Natural Resources to advise them of the Preferred Route. Mitigation measures will be updated should input be received by trappers. • Provide at least one year notice to the remote outfitters in advance of construction start. • Implement mitigation measures for air quality, noise, visual, surface water, fish, wildlife, and ungulates as outlined in the appropriate technical support documents. • The possession and use of firearms will not be permitted for construction personnel. • Restrict public access to the Community Access Road corridor during construction. Gate temporary access roads and block and restore as soon as possible after they are no longer needed. Permanent access roads used for maintenance activities will be gated while not in use. • Develop and implement an Environmental Protection Plan that includes the following measures to control,	• The Project is located in an area that has a number of remote outfitter commercial outpost camps on sites that are permitted through Land Use Permits from the Ministry of Natural Resources. Two camps would be directly impacted.	• Context: Social • Direction: Adverse • Magnitude: Medium • Geographic Extent: Local • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Certain • Significance: Not significant • Confidence: Low • Direct / Indirect: Direct

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
			and / or restrict public use of access roads during construction: speed limits, signage, reduced road standard, felling of timber across temporary access roads after reclaimed, removal of temporary watercourse crossings, reduce traffic by locating camps near construction sites. Posting of restricted access and speed signage will follow the Construction Specification for Temporary Traffic Control Devices (Construction Specification for Temporary Traffic Control Devices, 2016).		
• **Remote Outfitters**	• Operations	• Painter Lake camps and the Caviar Lake camp are likely to experience the highest impact from noise during construction and operation phases; however, noise levels are below or equal to the Health Canada Limit Guide of 55 A-weighted decibels. • Due to increased access to the area and to the commercial outpost camps, there could be increased fishing pressure on the waterways in proximity to the road which could also adversely impact species abundance. However, fish populations are expected to be self-sustaining and ecologically effective. • Though moose health is not expected to be affected and population is not expected to decrease in abundance because of the Project, there are concerns that with increased access to the area resulting from the construction and ongoing operations of the road that there could be an increase in illegal hunting / poaching and vehicle-wildlife collisions, which could adversely affect moose populations over time, adversely affecting remote outfitters number of tags if the Ministry of Natural Resources deems these impacts through Moose Aerial Inventory and hunter surveys. • Considering the construction of the Project is expected to contribute to a change in the remote / wilderness character of the area where some of the commercial outpost camps are located and could reduce their attractiveness to clients. The commercial outpost camps at most risk to this include: Painter Lake, due to a proposed aggregate pit on the north side of the lake; Caviar Lake, due to the crossing of the Albany River just to the east of the camp location (<1 kilometres and proposed pits to the south); and to a lesser extent Teabeau Lake, due to improved access to the Albany River and the potential for more boats / fishing in the area of that	• During operations, this assessment has been assumed that the Community Access Road will be accessible to the public but access roads for aggregate areas and other infrastructure required for maintenance activities will be gated to limit public access. Road maintenance staff will be prohibited from hunting or carrying firearms while working on the Project maintenance. • Consider provide signage along the Preferred Route to inform road users about possible interaction with recreation users and wildlife. • Consider installation of Crimestoppers signage that discourages poaching and provides the public with a number to call if witnessing poaching or illegal hunting. • Consider monitoring for vehicle-wildlife collisions and provide annual reports to the Ministry of Natural Resources to analyze impacts to populations due to vehicular collisions.	• The Project is located in an area that has a number of remote outfitter commercial outpost camps on sites that are permitted through Land Use Permits from the Ministry of Natural Resources. Two camps would be directly impacted.	• Context: Social • Direction: Adverse • Magnitude: Medium • Geographic Extent: Local • Duration: Life of the Project. • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Uncertain • Significance: Not significant • Confidence: Low • Direct / Indirect: Indirect

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
		camp. Because of the assumed public access changes, and potential noise impacts, these commercial outpost camps may become less attractive, and the remote outfitters may decide to sell their shares the structures on their Land Use Permit. This is considered to be a direct adverse effect to these business owners. Given new access opportunities to the Caviar Lake and Teabeau Lake commercial outpost camps (potentially accessible by boat via the Community Access Road) it may be possible to repurpose these commercial outpost camps as an option for boating in and be more economical for use.			
• **Trapping**	• Construction	• The Construction Disturbance Area intersects with seven traplines: – GE 138: 148.6 hectares – GE 148: 507.7 hectares – GE 153: 1,036.1 hectares – GE 154: 630.4 hectares – GE 157: 1,921.3 hectares – GE 159: 203.8 hectares – GE 164: 252.3 hectares • All seven traplines intersecting the Construction Disturbance Area will experience short-term noise effects at infrequent levels during construction and operations. • Given the little response from consultation with trappers, it may be justifiable to use Indigenous Knowledge locations of the traplines and trap locations in order to provide options for notification of future construction and disturbance expected in that area.	• Mitigation measures include providing notice to trapline holders of timeline and periods of construction and permitting access to Construction Disturbance Area as required for trapping activities throughout construction. • Signage placed on known areas of trapping access points will notify trappers of future construction activities. • Refer to mitigation measures for noise and wildlife outlined in the appropriate technical support documents. • The possession and use of firearms will not be permitted for construction personnel. • Access to the Community Access Road corridor will be restricted during construction to workers. • Temporary access roads and other temporary construction infrastructure will be reclaimed as quickly as possible following construction. • Beaver lodges will be marked as sensitive sites and protected. • Consider continued engagement with trappers throughout detail design phase. • An Environmental Protection Plan will be implemented that includes the following measures to control, and / or restrict public use of access roads during construction and operation: speed limits, gates / manned gates, signage, reduced road standard, felling of timber across temporary access roads after reclaimed, removal of temporary watercourse crossings, reduce traffic by locating camps near construction sites. Posting of restricted access and speed signage will follow the Construction Specification for Temporary Traffic Control Devices (Construction Specification for Temporary Traffic Control Devices, 2016).	• The Construction Disturbance Area intersects with seven traplines. Indigenous Knowledge provided by Marten Falls First Nation and Aroland First Nation indicates that the route passes through lands that have been used for trapping in the past but that very little trapping activity has occurred in the area in the last ten years due to continued low prices for furs. Continued engagement with trappers may provide additional information as detail design phase progresses.	• Context: Social • Direction: Neutral to Adverse • Magnitude: Low • Geographic Extent: Local • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Moderate certainty • Significance: Not significant • Confidence: Moderate • Direct / Indirect: Direct

Valued Component	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Trapping**	• Operations	• Increased mortality of furbearers from road traffic is possible. Increased human presence and road traffic noise could reduce furbearer populations in the immediate vicinity of the Project. Changes to regional populations are not predicted. It is also not possible to predict the impact of increased access to the area might have on the populations of these species. • Road is expected to improve access to the area for trapping and to allow additional methods of transporting furs to market.	• During operations, the Community Access Road will be accessible to the public but access roads for aggregate areas and other infrastructure required for maintenance activities will be gated to limit public access. Employees will be prohibited from hunting or carrying firearms while working on the Project maintenance.	• The Construction Disturbance Area intersects with seven traplines. Indigenous Knowledge provided by Marten Falls First Nation and Aroland First Nation indicates that the route passes through lands that have been used for trapping in the past but that very little trapping activity has occurred in the area in the last ten years due to continued low prices for furs. Continued engagement with trappers may provide additional information as detail design phase progresses.	• Context: Social • Direction: Neutral and positive • Magnitude: Low • Geographic Extent: Local • Duration: Long-term • Frequency: Continuous • Reversibility: Irreversible • Likelihood: Uncertain • Significance: Not significant • Confidence: Low • Direct / Indirect: Direct
• **Energy and Linear Infrastructure**	• Operations	• Introduction of the right-of-way corridor for the Community Access Road will introduce the possibility of energy and linear infrastructure projects. The Project is expected to have indirect positive impacts to this valued component.	• Any potential projects must undergo their own Environmental Assessment / Impact Assessment process to determine impacts and mitigation and enhancement measures.	• No residual effects	• Not applicable

9.5.8 Visual Environment

9.5.8.1 Project-Environment Interactions

For the Visual Environment, all Project activities are considered to have the potential to interact with, and thereby alter, visual conditions to some degree. This reflects the inherently perceptual nature of the discipline; where any visible physical change, even temporary, contributes to the alteration of landscape character or scenic quality. These activities include both construction-related activities (such as right-of-way clearing, aggregate extraction, bridge and culvert installation, and staging area development) and operations activities (such as ongoing road use, vegetation management, and infrastructure upkeep). **Table 9.5-8** shows the Project-environment interaction for the visual environment valued components.

Table 9.5-38: Project – Environment Interactions – Visual Environment

Community Access Road Phase	Community Access Road Activities	Valued Component	Indicator(s)	Description of Project-Environment Interaction
• **Construction** • **Operation**	• All Project Activities	• Cultural Heritage resources and Indigenous Experience and Sense of Place	• Views from culturally significant sites; traditional use corridors and waterways; harvesting, ceremony, and gathering places; including any area or location identified as integral to Indigenous experience and sense of place.	• Visual change at or near culturally significant sites; traditional use corridors and waterways; harvesting, ceremony, and gathering places; including any area or location identified as integral to Indigenous experience and sense of place.
• **Construction** • **Operation**	• All Project Activities	• Recreation and Tourism	• Views from designated trails and lookouts; canoe routes / portages and backcountry campsites; tourism lodges / outfitters and popular scenic viewpoints	• Visual change at or near designated trails and lookouts; canoe routes / portages and backcountry campsites; tourism lodges / outfitters and popular scenic viewpoints
• **Construction** • **Operation**	• All Project Activities	• Parks and Protected Areas	• Park landscape character and park views (for example, waterway corridors, designated lookouts, remoteness and wilderness character) as protected aesthetic resources in their own right	• Changes to Park landscape character and views
• **Construction** • **Operation**	• All Project Activities	• Permanent Settlements	• Views from residences, community facilities (for example, schools, health centres), public spaces and main streets, and approach roads within settlement areas.	• Changes to views from residences, community facilities (for example, schools, health centres), public spaces and main streets, and approach roads within settlement areas.

9.5.8.2 Discipline-Specific Characteristics

In support of the residual effects characteristics described in **Section 6.7.3**, **Table 6-1**, the following visual definitions apply to the effects assessment.

Ecological and Social Context

The Visual Environment is closely tied to cultural identity, sense of place, well-being, and lived experience for Indigenous Peoples, as well as to wilderness expectations for recreation users and park visitors. Indigenous Knowledge identified rivers, travel corridors, harvesting areas, and culturally important landscapes as places where visual integrity, and remoteness are highly valued. Even limited or localized visual change in these areas can be perceived as meaningful due to the pristine nature of the existing visual conditions.

The Project is situated in a largely intact boreal and wetland landscape with minimal existing infrastructure. Vegetation cover limits views in most areas, while major river corridors create open viewsheds that are visually prominent and sensitive to change.

Overall, all receptors and intrinsic park landscapes were conservatively classified as high sensitivity to visual change.

Magnitude

For magnitude, discipline-specific definitions are required and are provided **Table 9.5-39.**

Table 9.5-39: Visual Environment Magnitude Definitions

Magnitude Levels	Definition
• **Negligible**	• Visibility; Very minor alteration to one or more key elements, features, or characteristics of the existing condition. • Contrast; New elements blend such that the scene appears essentially unchanged. • Frequency / Exposure; Affected view is seen on very rare occasion (less than once a year) or not seen at all
• **Low**	• Visibility; Very minor alteration to one or more key elements, features, or characteristics of the existing condition. • Contrast; New elements are noticeable but generally compatible with landscape character. • Frequency / Exposure; Affected view is seen infrequently (once or twice per year)

Magnitude Levels	Definition
• **Medium**	• Visibility: Partial alteration to one or more key elements / features / characteristics of the existing condition. • Contrast: New elements are noticeable, but generally incompatible with the landscape character, but the change does not dominate the view. • Frequency / Exposure; Affected view is seen occasionally (transient views or travel corridors, or areas used several times per year).
• **High**	• Visibility: Total loss of or major alteration to key elements / features / characteristics of the existing conditions. • Contrast: Introduction of elements considered to be totally uncharacteristic when set within the attributes of the receiving landscape. • Frequency / Exposure: Affected view is seen on a regular basis. Usually for permanent residents or daily exposure.

9.5.8.3 Residual Effects – Construction Phase

9.5.8.3.1 Changes to Visual Environment

9.5.8.3.1.1 Potential Effects

Visual conditions can be expected to change, on occasion, due to construction activities associated with the Project. Visual change will be temporary in nature for construction-related elements (for example, equipment, temporary works, exposed soils) and generally localized within the Construction Disturbance Area, with effects extending into the Local Study Area where visibility is available (for example, open-water river corridors, open fen / peatland). The degree of visual change will depend primarily on (i) visibility (distance, screening, viewing angle, lighting conditions), (ii) contrast (colour / texture / line against sky, water, peatland vegetation, or forest backdrop), and (iii) frequency of exposure (presence and use patterns of Indigenous land users, recreationists, park users, and residents).

During construction, direct visual effects are expected at and near active work areas, particularly at major water crossings and staging locations. Temporary works (for example, bank grading, cofferdams where required, temporary platforms, safety fencing), cleared approaches, equipment movement, and exposed soils may be visible from water and shore. Visibility is typically highest in near- to mid-distance views along the Albany River and Ogoki River corridors, where strong contrast can occur when equipment and disturbed soils appear against reflective water and open sky. Viewer exposure for travel along these corridors is expected to be infrequent to occasional during active construction seasons, depending on seasonal use patterns.

At smaller watercourses and wetlands, short enclosed views in forest settings limit the visible extent of change; visibility is generally low-to-medium and contrast is typically

modest due to vegetative screening. In forested uplands, visibility is generally confined to the Construction Disturbance Area and immediate edges, with contrast driven by exposed mineral soils, stumps, and slash until progressive reclamation is implemented. In open fen and peatland settings, linear clearing may be perceptible at distance under certain lighting conditions due to tonal contrast between mineral surfaces and peatland vegetation.

Indirect visual effects during construction may include short-term dust deposition that lightens foliage near active works (increasing local contrast, particularly along haul routes) and minor early-stage edge effects (for example, localized windthrow or dieback) that may subtly widen sightlines until edges stabilize.

Construction effects to the visual environment are predicted to range from low to medium in magnitude depending on setting and receptor, with the highest magnitude localized at major crossing viewsheds (Albany River and Ogoki River) and within protected park viewscapes

9.5.8.3.1.2 Mitigation and Enhancement Measures

As visual effects are strongly influenced by design and execution details, the Project will implement the mitigation and enhancement measures to reduce visibility, reduce contrast, limit exposure where feasible. Measures include:

- Structure finishes (for example, matte or weathering finishes; non-glare details; avoidance of bright / specular surfaces) to reduce contrast against sky and water;
- Opening and edge form controls (for example, minimized clearing at shorelines; feathered edges; retained clumps / shrub screens; meandering limits where feasible);
- Shoreline shaping and materials (for example, naturalized grading; local rock; coarse woody debris for texture; rapid stabilization / planting);
- Construction lighting controls (for example, prohibition of floodlighting; downward-facing, fully shielded task lighting only; limits on dark-hours activity);
- Staging / stockpile placement outside principal view cones and with height controls where feasible;
- Seasonal scheduling windows for visually intrusive activities where feasible, coordinated with Indigenous communities, outfitters, and Ontario Parks;
- Dust and surface management (for example, suppressant application; prompt stabilization of exposed soils; stockpile controls); and
- Progressive reclamation (for example, salvage / respread organics; native seeding or regeneration; decommission temporary access; restoration of topography).

These measures are intended to reduce peak construction-period contrast and clutter, shorten the duration of visually prominent conditions, preserve dark-sky character, and maintain naturalized shoreline and corridor form—particularly within the Albany River Provincial Park and Ogoki River Provincial Park viewscapes and along culturally important river corridors.

9.5.8.3.1.3 Predicted Residual Effects

Visual change during construction may result in a potential residual effect because it is predicted that, after the implementation of mitigation and enhancement measures, noticeable visual change will still occur in localized settings (particularly at major crossings and within protected park landscapes) during active construction.

Residual construction effects are predicted to be not significant, with the primary rationale being that construction effects are temporary, localized to crossing viewsheds and work fronts, reversible for temporary works, and intermittently experienced by most receptor groups.

9.5.8.4 Residual Effects – Operations Phase

9.5.8.4.1 Changes to Visual Environment

9.5.8.4.1.1 Potential Effects

Visual conditions can be expected to change during operations due to the presence of permanent Project elements (for example, bridge structures, maintained corridor opening, and associated cleared edges) and intermittent operational activity (for example, vehicle visibility and headlight beams). Visual change during operations is expected to be long-term and localized to areas where the Project is visible, particularly at the Albany River and Ogoki River crossings and within park landscapes. The magnitude of visual change will vary based on distance and screening, landscape context, receptor use patterns, and the extent to which finishes, edge form, and vegetation management maintain visual compatibility with the surrounding natural character.

During operations, bridge structures at the Albany River and Ogoki River will be present in views along the river corridors. Visibility is high within near and mid-distance views from water and shore immediately around the crossings; contrast depends on final finish, profile, and backdrop conditions. Viewer exposure is expected to be occasional for most paddlers and shoreline users (in other words, typically encountered once per trip), while the structures remain continuously present in the landscape.

Smaller crossing structures are less visually prominent due to scale and enclosure and are typically experienced as short glimpses. In forested segments, the corridor is

generally screened; in northern fen / peatland settings, the corridor may appear as a subtle linear opening under specific light and distance conditions, with low-to-medium visibility and low contrast once surfaces weather and vegetation regrows along edges.

Indirect effects during Operations may include the ongoing influence of vegetation management in maintaining a visible opening, the potential for localized edge effects (for example, minor windthrow or dieback), and seasonal features such as winter snow windrows that can read as bright linear elements until melt. Under night conditions, where no continuous lighting is assumed, visibility related to operations is expected to be intermittent (for example, headlight beams near open-water crossings or community approach segments).

9.5.8.4.1.2 Mitigation and Enhancement Measures

Mitigation and enhancement measures relevant to Operations include: maintaining feathered edges and buffers through selective trimming where feasible, retaining shrubs for low-view screening, avoiding continuous lighting, and implementing community-specific screening where field validation identifies direct headlight lines of sight. Measures relating to finishes and edge form (co-developed with Indigenous knowledge holders and community members during detail design) are intended to confirm permanent elements remain visually subordinate and compatible with protected river corridor and park landscape character.

9.5.8.4.1.3 Predicted Residual Effects

Visual change during operations may result in a potential residual effect because it is predicted that, after the implementation of mitigation and enhancement measures, permanent structures and maintained corridor openings will remain visible in localized viewsheds (particularly at major crossings and within protected parks) and intermittent operational visibility (vehicles / headlights) may occur near certain receptor locations.

Residual operational effects are predicted to be not significant, with the primary rationale being that post-mitigation effects are generally low in magnitude at the broader viewshed / landscape scale, with medium-magnitude effects limited to very close-range conditions at crossing viewpoints. Exposure for most receptors is occasional and spatially constrained, and overall park-scale and landscape-level visual character is expected to remain intact.

9.5.8.5 Summary of Residual Effects

Table 9.5-40 provides a summary of the potential effects for visual environment, mitigation measures, and residual effects. Detailed information is included in **Appendix V**.

Table 9.5-40: Summary of Residual Effects – Visual Environment

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Visual Environment (Cultural Heritage Resources and Indigenous Experience and Sense of Place; river corridor viewscapes and broader visual network)**	• Clearing, grading, earth moving, grubbing of vegetation, and stockpiling of materials along the right-of-way and other access and construction areas, and construction of infrastructure (for example, access roads, bridges, temporary laydown areas, turn-around areas, and temporary construction camps) • Temporary works at water crossings (for example, bank grading, cofferdams where required, temporary works platforms, safety fencing) • Staging areas and haul routes • Reclamation and decommissioning of temporary access roads, temporary laydown areas, staging areas and construction camps	• Construction	• Construction activities may result in temporary changes to visual character and views due to the presence of equipment, temporary works, cleared approaches, exposed mineral soils, and short-term dust deposition. • Effects are most noticeable at Albany River and Ogoki River crossing viewscapes (high visibility from water and shore; potential strong contrast against reflective water and sky), and in open fen / peatland segments where linear clearing can be perceptible at distance under specific light conditions.	• Use matte or weathering finishes for steel; consider colour or texture for exposed concrete; non-glare fasteners; avoid bright, specular surfaces. • Stake meandering clearing limits; keep visible openings at shorelines to the smallest practicable width; feather edges with retained clumps and shrub screens where possible. • Shape abutments and approach embankments to follow adjacent slopes where possible; use local rock; place coarse woody debris to restore texture; implement rapid stabilization and planting within the same season where possible. • Prohibit floodlighting; allow downward-facing, fully shielded task lights only; enforce dark-hours. • Site temporary staging, batch plants, and stockpiles behind landforms or retained vegetation where possible; cap material or equipment stack heights below the treeline where feasible. • Schedule visually intensive tasks outside peak paddling and cultural use periods identified with communities and outfitters where feasible. • Apply water or equivalent suppressant; cover or stabilize stockpiles; promptly stabilize exposed soils; clean hard surfaces at staging areas. • Salvage and respread organics; seed with native species or allow natural l regeneration; decommission temporary access; restore topography (progressive reclamation) • Co-develop finish palette, edge form, and opening limits with Indigenous knowledge holders and community members, including site walks and field reviews before final clearing. • Provide clear advance notices for intrusively visible works; maintain one or more quiet, dark vantage spaces away from bridge view for elders and youth during key seasons.	• Residual changes to river corridor and broader Indigenous visual network	• Context: Highly valued visual corridors that provide both cultural heritage resource value and provide sense of place • Direction: Negative • Magnitude: Medium at and near Albany River and Ogoki River crossings; Low to negligible elsewhere (post-mitigation) • Geographic Extent: Localized to crossing viewscapes and Construction Disturbance Area; may extend into portions of the Local Study Area where visibility exists • Duration: Short- to medium-term • Frequency: Occasional to frequent during active construction seasons in river corridors; otherwise infrequent • Reversibility: Partially Reversible for temporary works and construction-related visual clutter • Probability: Certain • Significance: Not significant • Uncertainty: Low–Moderate to Moderate (varies by setting) • Direct / Indirect: Direct

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Visual Environment (Recreation and Tourism; backcountry user experience and scenic integrity)**	• Same as above (construction clearing and infrastructure development; temporary works at crossings; staging and haul routes; reclamation / decommissioning)	• Construction	• Construction activities may result in temporary visual disturbance in near- to mid-distance views for backcountry canoeing / camping / angling / hunting users, particularly at water crossings and staging areas. • Elsewhere, effects are brief and screened in forested segments; short-term dust and localized turbidity may reduce perceived naturalness near active works.	• Opening and edge form controls (minimize shoreline opening; feather edges; retain shrubs / clumps). • Staging outside view cones; height controls below treeline where feasible. • Dust and surface management. • Progressive reclamation (rapid stabilization; organics respread; regeneration • Seasonal windows to avoid peak paddling and cultural use periods where feasible. • Construction communications and advance notices for intrusively visible works.	• Residual changes to remote backcountry setting	• Context: Recreation and Tourism • Direction: Negative • Magnitude: Medium at crossing viewscapes; Low elsewhere • Geographic Extent: Localized (crossings and Construction Disturbance Area) • Duration: Short- to medium-term • Frequency: Occasional (intermittent user exposure; seasonal) • Reversibility: Reversible for temporary works • Probability: Certain • Significance: Not significant • Uncertainty: Low–Moderate • Direct / Indirect: Direct
• **Visual Environment (Parks and Protected Areas; protected landscape character within Albany River Provincial Park and Ogoki River Provincial Park)**	• Clearing and construction within regulated park boundaries where applicable • Temporary works at water crossings and approaches • Construction lighting, staging, and shoreline grading • Reclamation of temporary works areas	• Construction	• Construction activities may result in temporary visual intrusions within protected viewscapes (cleared approaches, equipment, temporary works). • Construction lighting may affect night sky viewing and nighttime wilderness character if not controlled. • Short-term dust/turbidity may reduce scenic integrity near active works.	• Lighting controls (no floodlighting; shielded downward task lighting only; dark-hours). • Staging / stockpiles outside view cones; treeline height controls. • Shoreline shaping and naturalized grading; local rock; coarse woody debris for texture; rapid stabilization/planting. • Minimize shoreline clearing and feather edges. • Seasonal windows where feasible. • Communication / advance notice. • Design and construction to be demonstrably consistent with Waterway-class objectives and applicable management statements / Ontario Parks authorization requirements (as applicable).	• Residual changes to protected aesthetic resources and wilderness character	• Context: Parks and Protected Areas • Direction: Negative • Magnitude: Low-to-medium • Geographic Extent: Local (Construction Disturbance Area within parks and immediate crossing viewscapes) • Duration: Short- to medium-term • Frequency: Continuous within the park landscapes while works are present; intermittent for individual visitors • Reversibility: Reversible for temporary works • Probability: Certain • Significance: Not significant • Uncertainty: Low • Direct / Indirect: Indirect

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Visual Environment (Permanent Settlements; Marten Falls community outward views and Albany River shoreline cabins)**	• Construction works near community approach (clearing, grading, equipment movement) • Temporary lighting and haul traffic • Dust generation along routes	• Construction	• Construction activities may result in temporary changes to views and nighttime character near the community approach due to equipment visibility, intermittent lighting, movement, and dust. • At shoreline cabins, low-to-medium visual change may occur when construction is nearby and cabins are in use.	• Construction lighting controls (shielded task lighting; dark-hours; no floodlighting). • Dust control and prompt stabilization of exposed soils. • Staging outside view cones where feasible. • Communication and advance notice for intrusively visible works.	• Residual changes to residential communities with the remote wilderness settings and cabins that are intermittently occupied.	• Context: Permanent Residents • Direction: Negative • Magnitude: Low (community); Low-to-medium when works nearby (cabins) • Geographic Extent: Local (Construction Disturbance Area and portions of LSA where Project is perceptible) • Duration: Short- to medium-term • Frequency: Infrequent to occasional (community); occasional when cabins in use • Reversibility: Reversible for temporary works • Probability: Probable to Certain (depending on proximity/timing of works) • Significance: Not significant • Uncertainty: Moderate • Direct / Indirect: Direct
• **Visual Environment (Cultural Heritage Resources and Indigenous Experience and Sense of Place; river corridor viewscapes and broader landscape)**	• Operations of the right-of-way and permanent access roads • Presence of permanent bridge structures at Albany River and Ogoki River • Routine vegetation management • Winter maintenance (for example, snow windrows) • Intermittent vehicle visibility and headlight beams (no continuous lighting assumed)	• Operations	• Operations may result in long-term changes to visual character and views due to the presence of permanent bridge structures and maintained corridor opening, with localized medium-magnitude effects in very close-range river crossing views and generally low-magnitude effects in broader viewsheds after mitigation. • Indirect effects may include maintained openings due to vegetation management and seasonal snow windrows; intermittent headlight beams may be perceptible near open-water crossings and the community approach.	• Use matte/weathering finishes; avoid specular surfaces on bridges and visible barriers. • Maintain buffers and feathered edges; selective trimming over broad brushing; retain shrubs for screening. • Do not install continuous road or bridge lighting; task lighting only for incidents/maintenance. • Where validation identifies direct headlight lines of sight near the community approach, install low vegetated berms or dense planting; micro-site within right-of-way where practicable. • Co-develop final finish palette and edge form with Indigenous knowledge holders and community members during detail design.	• Residual changes to high cultural value river corridors and remote wilderness settings.	• Context: Highly valued visual corridors that provide both cultural heritage resource value and provide sense of place • Direction: Negative • Magnitude: Low in most views; Medium at very close range at Albany and Ogoki crossings • Geographic Extent: Localized to crossing viewscapes and visible portions of the corridor within the Local Study Area • Duration: Long-term • Frequency: Occasional (river travel); infrequent elsewhere • Reversibility: Irreversible for permanent structures and maintained corridor opening • Probability: Certain • Significance: Not significant • Uncertainty: Moderate • Direct / Indirect: Direct

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Visual Environment (Recreation and Tourism; scenic integrity and backcountry experience)**	• Same as above (permanent bridges, maintained corridor opening, intermittent vehicles/headlights, vegetation management, winter maintenance)	• Operations	• Operations may result in long-term change to scenic integrity at major river crossings due to bridge presence contrasting with expectations of uninterrupted natural shorelines and open-water vistas; smaller crossings and screened forest segments are less prominent. • Nighttime visibility is intermittent (headlights) with no continuous lighting assumed.	• Bridge finish controls (matte/weathering). • Vegetation management to maintain screening and feathered edges. • No continuous lighting.	• Residual changes to backcountry recreation with high expectation of intact natural character.	• Context: backcountry recreation with high expectation of intact natural character. • Direction: Negative • Magnitude: Low in most views; Medium at very close range at crossings • Geographic Extent: Local (crossing viewscapes; limited corridor visibility) • Duration: Long-term • Frequency: Occasional • Reversibility: Irreversible • Probability: Certain • Significance: Not significant • Uncertainty: Low–Moderate • Direct / Indirect: Direct
• **Visual Environment (Parks and Protected Areas; protected landscape character)**	• Permanent bridges and associated clearing within park landscapes • Routine maintenance (vegetation management; winter snow features) • No continuous lighting (assumed)	• Operations	• Operations may result in long-term, localized alteration of protected scenic character due to permanent bridge structures and maintained openings within the park landscapes. • Effects are generally low at the park scale, with localized medium-magnitude effects limited to close-range crossing views.	• Bridge finishes to reduce contrast and glare. • Vegetation management to maintain buffers and screening; selective trimming. • No continuous lighting. • Ongoing alignment with Ontario Parks authorization requirements and applicable management direction (as applicable).	• Residual changes to protected aesthetic resources	• Context: Parks and Protected aesthetic resources • Direction: Negative • Magnitude: Low in most views; Medium at very close range • Geographic Extent: Local (park landscapes near crossings / Construction Disturbance Area) • Duration: Long-term • Frequency: Continuous within park landscapes • Reversibility: Irreversible for structures and maintained opening • Probability: Certain • Significance: Not significant • Uncertainty: Low • Direct / Indirect: Direct

Valued Component	Project Activities	Project Phase	Description of Potential Effect	Mitigation and Enhancement Measures	Predicted Residual Effect	Characterization of Predicted Residual Effect and Determination of Significance
• **Visual Environment (Permanent Settlements; Community and cabins)**	• Vehicle movement and intermittent headlight beams on approach segments • Maintained corridor opening • Vegetation management • No continuous lighting	• Operations	• Operations may result in low-level, intermittent visual presence of vehicles and headlight beams near the community approach and select outward-facing viewpoints depending on micro-siting and vegetation. • At shoreline cabins, operations may result in low-magnitude, intermittently experienced changes where the Project is perceptible.	• No continuous lighting. • Community-specific screening where field validation identifies direct headlight lines of sight (low vegetated berms, dense planting; micro-siting within right-of-way). • Vegetation management to retain screening.	• Residual changes to residential community and remote cabins within a wilderness setting.	• Context: Residential community and remote cabins within a wilderness setting. • Direction: Negative • Magnitude: Low • Geographic Extent: Local (portions of Local Study Area where Project is perceptible) • Duration: Long-term • Frequency: Infrequent to occasional • Reversibility: Irreversible for permanent corridor/structures; intermittent operational visibility • Probability: Certain (where visible) • Significance: Not significant • Uncertainty: Moderate • Direct / Indirect: Direct

9.5.9 Assessment of Significance of People Disciplines

The assessment of significance of residual effects of the Community Access Road is informed by the interaction between the significance factors, with magnitude and geographic extent being the most important factors. Consideration is also given to context, which includes ecological context (in other words, the sensitivity and resilience of the valued components), and social context (in other words, concerns of Indigenous communities, interested agencies, groups and individuals raised during consultation and engagement and through review comments on the Environmental Assessment reports). Implementation of proven mitigation measures is expected to aid in the avoidance or reduction of the magnitude, geographic extent, and / or duration of residual effects.

9.5.9.1 Determination of Significance

Using the overall residual effects characteristics for each discipline, each of the potential residual effects was assigned a significance level as a means of ranking the potential effects on the surface water quantity, surface water quality, and sediment quality. The significance levels are defined as:

- Significant: residual effects were considered to be significant if the majority of the residual effects characteristics were assessed as high in magnitude and long-term or permanent in duration, at any geographic extent, or they represented a management concern; and
- Not Significant: residual effects were considered not significant if they demonstrated any other combination.

9.5.9.2 Aboriginal and Treaty Rights and Interests

An assessment of significance is outlined in each confidential Aboriginal and Treaty Rights and Interests Report.

9.5.9.3 Acoustic Environment

Because the residual effects from the increased noise during construction are not predicted to be long-term in duration or frequent, the residual effects during construction are assessed as not significant.

As the magnitude of the residual effects from the increased noise due to road operations is low, and the residual effects from the increased noise due to quarry use are not predicted to be frequent, the residual effects during operations are assessed as not significant.

Because the residual effects from the increased vibration during construction are not predicted to be long-term in duration or frequent, the residual effects during construction are assessed as not significant.

Because the residual effects from the increased vibration during operations—from quarry blasting—are not predicted to be long-term in duration or frequent, the residual effects during operations are assessed as not significant.

9.5.9.4 Atmospheric Environment

9.5.9.4.1 Air Quality

Residual effects were generally considered as significant if the residual effect was assessed at a high magnitude with potential residual impacts occurring at sensitive receptors, at either a frequent occurrence or in long term duration with irreversible effects. The construction phase is both transient in nature as well as temporary (short term), and the residual effects are considered reversible. Through the significance assessment it was found that no significant residual effects in the context of air quality are anticipated through construction.

It is noted that that select construction activities may result in receptors experiencing air quality levels considered to be high magnitude (in other words, elevated levels of sulphur dioxide from blasting) however, as previously indicated these activities occur infrequently, over a short term duration and are not considered to result in a significant residual effect. This finding was largely driven by the reversibility of air quality effects from construction activity. It should be noted that a maximum number of daily and annual blasts was considered as part of this assessment. In the event that blasting frequency is reduced the frequency of potential effect will also decrease. Residual effects from operations that were classified to have a high magnitude were determined to be significant**.** High magnitude impacts are predicted for the following indicator compounds and their respective averaging periods:

- Particulate matter less than 2.5 micrometres – 24-hour – north-south road segment – 115 metres from road;
- Particulate matter less than 2.5 micrometres – annual – north-south road segment – 134 metres from road;
- Particulate matter less than 10 micrometres – 24-hour – north-south road segment – 1,986 metres from road;
- Particulate matter less than 10 micrometres – 24-hour – community road segment – 10 metres from road;

- Total Suspended Particulate – 24-hour – north-south road segment – 3,004 metres from road;
- Total Suspended Particulate – 24-hour – Community Access Road segment – 119 metres from road; and
- Total Suspended Particulate – annual – north-south road segment – 899 metres from road.

All other indicator compounds were determined to be not significant.

9.5.9.4.2 Greenhouse Gases

Despite the potential implementation of mitigation measures, the road construction and subsequent vehicle traffic on the road will continue to produce greenhouse gases. Although improvement in future emission control technologies for construction mobile equipment and vehicles may reduce total greenhouse gas emissions, the residual emissions from Construction and Operations are unavoidable. When comparing to provincial transportation sector greenhouse gas totals, the magnitude of both Construction and Operations emissions are assessed negligible, and the significance of residual effects is assessed as not significant.

Construction will lead to changes in land uses (for example deforestation) which release carbons stored in vegetation and soil. Although the Community Access Road is planned to use improved construction techniques (for example floating road) to minimize disturbances on wetlands, the residual effects of greenhouse gases from land use changes can not be fully eliminated. The Project's emissions from land use changes are assessed as low magnitude when compared to Ontario's total greenhouse gases and therefore the significance of emissions from land use changes are determined as not significant.

9.5.9.5 Archaeological and Cultural Heritage

An assessment of significance is not required for archaeological and cultural heritage.

9.5.9.5.1 Community Well-Being

Considering the assessment of potential residual effects, including both positive outcomes and adverse impacts, the some of the indicators for community well-being are considered significant.

Key positive effects include improved accessibility to and from Marten Falls First Nation, leading to small increases in on-reserve population, positive effects on productivity and

economic growth, and sustained tax revenues. Year-round access will also reduce the cost of essential goods such as bottled water and building materials, making everyday necessities more affordable. Additionally, improved transportation will create new opportunities for local businesses, employment, and community development, contributing to long-term resilience.

Key residual effects that are significant include mental health and well-being due to loss of connectivity to the land, change in sense of place and identity due to presence of the road; potential increase in substance use due to easier access to drugs and alcohol; reduction in availability of traditional foods due to construction disturbances to traditional food sources; reduction in availability of traditional foods due to overharvesting and environmental strain from the road; quality of traditional foods due to potential contamination; increase in violence and harassment; and environmental effects on air, water, soil due to contaminants, and noise levels may affect human health directly or indirectly.

Ongoing monitoring and adaptive management will support effective management of these effects.

9.5.9.6 Land and Resource Use

Considering the characterization of potential residual effects, residual effects on all valued components – land use compatibility, parks and protected areas, recreation and tourism, extractive resource industry, forestry industry, remote outfitters, trapping and energy and linear infrastructure – are assessed as not significant**.**

9.5.9.6.1 Visual Environment

The assessment shows that residual visual effects of the Project are highly localized and primarily associated with the major water crossings. With the committed mitigation and adaptive follow-up measures in place, no significant adverse residual effects are expected at the scale of the visual environment discipline or for any visual environment valued component.

Visual change is concentrated at discrete locations, while the majority of the route results in low-magnitude and not significant effects. Open-water views at the Ogoki River and Albany River Crossings expose bridge profiles and shoreline openings; however, following mitigation, residual visual magnitude is low in typical approach and mid-distance views. Medium-magnitude visual change is limited to very close-range viewpoints along the river view axis, generally within approximately 250 to 400 metres of the crossings. These localized effects do not alter the broader cultural, recreational, or protected landscape experience and do not result in significant residual effects.

10. Cumulative Effects Assessment

The *Impact Assessment Act* (Government of Canada, 2017a) requires that each Impact Statement of a project take into account any cumulative environmental effects that are likely to result from the project in combination with the environmental effects of other physical activities that have been or will be carried out. Additionally, this Cumulative Effects Assessment has been prepared in accordance with the Terms of Reference Notice of Approval for the Community Access Road.

This section presents the assessment of potential cumulative effects completed as part of the Community Access Road. The effects of past and present activities on the Study Area and valued components identified for the Community Access Road were assessed. A summary of results is provided in the following sections, and more details supporting this Cumulative Effects Assessment can be found in **Appendix F** to **Appendix Y**.

The Cumulative Effects Assessment builds on the results of the effects assessment described in **Section 9** and will consider the incremental changes that are predicted to have a likely residual adverse effect on a valued component.

10.1 Spatial and Temporal Scoping

As noted in **Section 6**, a Project Inclusions List was prepared as part of the Cumulative Effects Assessment to determine physical activities that may have a spatial or temporal overlap with the Community Access Road. The Project Inclusions List includes details regarding infrastructure projects in northern Ontario, where information was publicly available from online sources. **Table 10.1-1** shows the complete Project Inclusions List, and the locations of each project are shown on **Figure 10.1-1**.

A scoping exercise was completed to determine which projects had a spatial or temporal overlap with the Local and Regional Study areas identified for each of the valued components carried forward from the residual effects assessment. The sections below discuss the cumulative effects based on the results of the discipline scoping exercise. A summary of projects included in each discipline assessment, spatial and temporal overlap, and identification if a project or activity is reasonably foreseeable is included in **Table 10.2-4**, **Table 10.3-3**, and **Table 10.4-3**. The complete discipline scoping results for each project activity are included in **Appendix F** to **Appendix Y**.

Table 10.1-1: Project Inclusions List

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Northern Road Link	Yes	Between Community Access Road and Webequie Supply Road, northwestern Ontario	Impact Assessment ongoing	0 (adjacent or overlapping)	Webequie First Nation Marten Falls First Nation	October 28, 2020	Unknown	Unknown	Yes - construction and operation will overlap with Community Access Road construction, as it is expected that Northern Road Link construction will begin during the construction of the northern portion of the Community Access Road	• Marten Falls First Nation and Webequie First Nation are proposing to build, operate and maintain an all-season multi-use road and associated infrastructure between the community access road that has been proposed by Marten Falls First Nation and the supply road that has been proposed by Webequie First Nation. • Terms of Reference for the preparation of an Environmental Assessment approved March 3, 2023.	Line	100 metres
Anaconda and Painter Lake Forestry Access Road Upgrades	Yes	James Bay Lowlands	Unknown	0 (adjacent or overlapping)	In discussions: Ministry of Transportation and Aroland First Nation	Not Started	2 to 5 years	Unknown	Yes - operation is expected to overlap with the Community Access Road construction and operations	• Upgrades to existing road will be required for heavy vehicles accessing the Community Access Road route during construction and operations. • Currently discussions on proponency and scope of work are underway. • Potential scope of work is expected to include roadway widening, culvert and bridge replacements / rehabilitations to accommodate higher weight vehicles, and road base improvements. • This project will be completed prior to the start of the construction of the Community Access Road; therefore, the upgrade to these roads is not expected to overlap with the construction of the Community Access Road.	Line	100 metres
Rapid Lynx Broadband	Yes	Matawa First Nation communities	Phase 1 Complete Phase 2 Ongoing	Phase 1 - 0 (adjacent or overlapping) Phase 2 - 57.7	Rapid Lynx	February 2020	Unknown	Unknown	Yes - operations of Phase 1 and operations and construction of Phase 2 expected to overlap with Community Access Road construction and operations	• Approximately 810 kilometres of fibre-optic cables, providing reliable high-speed internet service to five Matawa First Nation communities: Eabametoong, Marten Falls, Neskantagat, Nibinamik and Webequie with an interconnection at Aroland.	Line	100 metres
Esnagami Road Bypass Upgrade	Yes	Aroland First Nation	Unknown	51.9	In discussions: Municipality of Greenstone, Ministry of Transportation, and Aroland First Nation	Not Started	2 to 5 years	Unknown	Yes - construction expected to overlap with Community Access Road construction	• Upgrades to existing road to use as a bypass route around Aroland First Nation settlement area by heavy vehicles accessing the Community Access Road route towards the Ring of Fire. • Currently discussions on proponency and scope of work are underway. • Potential scope of work is expected to include roadway widening, bridge and culvert rehabilitation / replacement, and road base improvements.	Line	100 metres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Transload Facility	Yes	Aroland, Ontario	Ongoing	59.5	Wyloo	Unknown	Unknown	Unknown	Yes - construction and operations expected to overlap with Community Access Road construction and operations	• Rail Transload Facility to Aroland First Nation.	Point	2.5 kilometres
Eagle's Nest Project	Yes	James Bay Lowlands	Permitting ongoing	97.8	Wyloo	2023	Approximately 11 years, with possible extension of 9 years	Unknown	Yes - construction expected to overlap with Community Access Road construction Operations expected to overlap with Community Access Road construction and operations	• Multi-metal underground mine located near McFaulds Lake. • Mine will produce and supply nickel, copper, platinum and palladium. • Deposit contains approximately 11 million tonnes of resources and is estimated to have an initial mine life of 11 years with possibility for a 9-year extension. • Terms of Reference for the project approved June 18, 2015.	Polygon	Not applicable
Webequie Supply Road	Yes	McFaulds Lake (eastern limit) Webequie First Nation (western limit)	Impact Assessment ongoing	98.5	Webequie First Nation	August 28, 2019	Unknown	Unknown	Yes - construction and operations will overlap with Community Access Road construction (expected to occur concurrently)	• New all-season road approximately 107 kilometres in length from Webequie First Nation to the mineral deposit near McFaulds Lake for mineral exploration and future mining development activities. • 17 kilometres of the corridor is within Webequie First Nation Reserve Lands.	Line	100 metres
Ogoki and Long Lac Diversions	Yes	Ogoki Lake and Long Lac, Ontario	Operating	95.8 (Ogoki) 87.0 (Long Lac)	Ontario Power Generation	1939 / 1943 respectively	Unknown	Unknown	Yes - operations overlap with Community Access Road construction and operations	• Divert water from a portion of the Hudson Bay watershed into the Lake Superior basin. • Dammed the upper Kenogami River, a tributary of the Albany River, on the north side of Long Lake. • Long Lac diversion inflows approximately 39 cubic metres per second into the Great Lakes Basin. • Ogoki diversion inflows approximately 113 cubic metres per second into the Great Lakes Basin.	Point	2.5 kilometres
Winter Access Road Realignment Project	No	Various	Ongoing	0	Ministry of Northern Economic Development and Growth	2025	Unknown	Unknown	Yes - construction and operations will overlap with Community Access Road construction (expected to occur concurrently)	• Funding to remote northern communities for projects involving installation of water crossing infrastructure, such as pre-engineered bridges and culverts, and repairs to existing structures. • Funding for approximately 3,200 kilometres of winter access roads in Northern Ontario.	Line	100 metres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Water Control Structures Along the Albany River Watershed	No	Albany River Watershed	Operating	Cedars Channel North Control Dam - 241.6 Cedars Channel South Control Dam - 241.6 Cedars Channel Block Dam - 241.5 Rat Rapids South Control Dam - 241.5 Rat Rapids North Control Dam - 241.5	Ontario Power Generation	Unknown	Unknown	Unknown	Yes - operations expected to overlap with Community Access Road construction	• Series of dams on the Albany River to generate power for newly opened gold mines at Pickle Lake. • Includes the Cedars Channel Dams and Rat Rapids Dams (located at Lake St Joseph).	Point	2.5 kilometres
Seymour Lake Lithium Project	No	Seymour Lake	Ongoing	131.3	Green Technology Metlas	2026	Unknown	Unknown	Yes - operations overlap with Community Access Road construction and operations	• Lithium deposit near Seymour Lake. • First production targeted in 2026.	Polygon	Not applicable
Juno Corporation Mining Exploration Activities	No	375 kilometres North of Longlac, Ontario	Ongoing	159.8	Juno Corp.	2019	Unknown	Unknown	Yes - operations overlap with Community Access Road construction and operations	• Exploration of minerals in the Ring of Fire. • Mineral exploration permit issued in August 2025.	Point	2.5 kilometres
Equinox Gold Greenstone Gold Mine	Yes	Geraldton, Ontario	Construction	112.8	Equinox Gold Corp.	October 2021	36 years	2044	Yes - operations expected to overlap with Community Access Road construction and operations	• Construction, operation, decommissioning and abandonment of an open-pit gold mine and onsite metal mill located near Geraldton, Ontario. • Production estimated at 30,000 tonnes per day. • Amended Decision Statement issued February 10, 2021. • First gold pour is anticipated in early 2024.	Polygon	Not applicable
Victor Mine	Yes	James Bay Lowlands	Closed - Rehabilitation ongoing	172.1	De Beers	2008	Unknown	Mine closed in 2019, ongoing rehabilitation - timing unknown	Yes - rehabilitation expected to overlap with Community Access Road construction	• Fly-in, fly-out open put diamond mine located near James Bay lowlands of northern Ontario. • Mine in operation from 2008 to 2019; however, now closed and in rehabilitation.	Polygon	Not applicable
Realignment of Highway 11 Project	No	Between Pearl Lake and Ouimet	Ongoing	260.7	Ministry of Transportation	2022	Unknown	Unknown	Yes - construction and operation expected to overlap with Community Access Road construction and operations	• Twinning of the existing Highway 11 at the east and west limits. • Rehabilitation and improvement of existing highway lanes. • New alignment for eastbound lanes. • Detail design of the project is ongoing.	Line	100 metres
Upgrades to Highway 11 to the Ring of Fire	No	Geraldton, Ontario	Ongoing	109.7	Indigenous Affairs and First Nations Economic Reconciliation	2025	Unknown	Unknown	Yes - construction and operation expected to overlap with Community Access Road construction and operations	• Connection of Highway 11 to Highway 584 to improve road access between Northern communities and to the provincial highway network. • First segment on the road network to the Ring of Fire.	Line	100 metres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Gull Bay Roads Rehabilitation	No	Gull Bay First Nation	Impact Assessment Complete	202.6	Gull Bay First Nation	2020	Unknown	Unknown	Yes - construction expected to overlap with Community Access Road construction	• Rehabilitate approximately 10 kilometres of roads in the Gull Bay First Nation in Ontario. • Relocation of the community's entrance and exit to Highway 527; rebuilding the road base and widening certain sections; grading and brush clearing to improve sightlines; addressing drainage issues through ditching and the replacement of an estimated 43 culverts; installing street and traffic control signs (for example street, stop, yield and speed signs plus pedestrian warnings); and resurfacing Main Street and Streets A through M with Granular A along with calcium chloride for dust suppression. • Infrastructure Canada issued its Notice of Determination on July 15, 2021, and determined that the project is not likely to cause significant adverse environmental effects.	Line	100 metres
East-West Tie Transmission Line Project	No	Between Wawa and Thunder Bay, Ontario	Operating	210.1	NextBridge Infrastructure LP	2019	Operations are indefinite	Not applicable	Yes -operations expected to overlap with Community Access Road construction and operations	• 450 kilometres double-circuit 230 kilovolts transmission line connecting the Lakehead Transfer Station to the Wawa Transfer Station, and the Marathon Transformer Station. • Project consists of transmission structures, insulators, conductors, overhead shield wires and optic fibre ground wires and grounding. • Will be operated on an ongoing basis for an indeterminate period of time. Decommissioning of the project is not anticipated at this time. • Construction completed in March 2022.	Line	100 metres
Copper - Generation Mining Ltd. Copper - Palladium Project	Yes	Marathon	Impact Assessment Ongoing	210.5	Generation Mining Ltd.	August 2011	Operation estimated at 12.5 years, decommissioning period unknown	Unknown	Yes - construction expected to overlap with Community Access Road construction Yes - operations expected to overlap with Community Access Road operations	• Construction, operation, and decommission of an open-pit palladium mine approximately 10 kilometres from Marathon, Ontario. • Includes three open pits, an ore processing plant, tailings and mine rock storage facilities, site access roads, transmission line, explosives factory, water management facilities, and temporary mine infrastructure. • Projected to produce a total of 3.6 million ounces of Palladium Equivalent (PdEq) over its current 12.5-year mine life.	Polygon	Not applicable
Wataynikaneyap Transmission Project	Yes	Between 90 kilometres north of Red Lake and 160 kilometres east of Pickle Lake	Phase 1: Operation Phase 2: Construction	Phase 1 - 236.5 Phase 2 - 198.7	Wataynikaneyap Power	2019	Unknown	Unknown	Yes - operations expected to overlap with Community Access Road construction and operations	• Construction of a 230 kilovolts line between Ignace and Dryden, to Pickle Lake (Phase 1). • Construction of electricity transmission lines to Pickle Lake and north of Red Lake, connecting 17 remote northern Ontario communities to grid power (Phase 2). • Operation of both project phases overlap with the construction and operations of the Community Access Road.	Polygon	100 metres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Kasabonika Lake First Nation Band Representative Facility	No	Kasabonika Lake First Nation	Impact Assessment Ongoing	239.4	Kasabonika Lake First Nation	September 13, 2023	Unknown	Unknown	Yes -construction expected to overlap with Community Access Road construction	• The Kasabonika Lake First Nation Band Representative Facility project involves the construction of a new single-story Child and Family Service building and housing facilities for staff in the community of Kasabonika Lake. • Includes tree clearing, lot development, parking lot and laneway construction, connection to community's water and wastewater infrastructure and building construction.	Point	2.5 kilometres
Sugar Zone Gold Project	Yes	White River	Operating	238.9	Harte Gold Corp.	2019	Operation expected to be completed in 2029, decommissioning period unknown	Unknown	Yes - operations expected to overlap with Community Access Road construction	• High grade underground quartz mine in northern Ontario within the Dayohessarah Greenstone Belt. • Average milling rate of 575 tonnes per day.	Polygon	Not applicable
Accelerated High-Speed Internet Program	No	Across Ontario	Ongoing	Varies	Ministry of Infrastructure	August 4, 2022	Approximately 3 years	Anticipated end of 2028	Yes - construction and operation expected to overlap with Community Access Road construction	• Providing access to reliable, high-speed internet to unserved and underserved communities across the province by the end of 2028.	Line	100 metres
Mushkegowuk James Bay All-Season Road Coastal and Inland	No	James Bay Region, Ontario	Ongoing	Coastal - 251.3 Inland - 327.8	Mushkegowuk Council	Unknown	Unknown	Unknown	Yes - operations overlap with Community Access Road operations	• New all-season access road connecting four western James Bay communities and the Provincial highway network. • Includes 525 kilometre of gravel-surface public highway, 70 bridges and 100 additional medium and large diameter culverts to span watercourses.	Line	100 metres
Kashechewan First Nation - 20 Lot Development	No	Kashechewan First Nation (Ontario)	Impact Assessment Completed	261.2	Kashechewan First Nation (Ontario)	October 10, 2023	Unknown	Unknown	Yes - construction expected to overlap with Community Access Road construction	• Development of 20 lots with future use to build family homes for the community. • Each lot is roughly 929 metres in size. • The project will include site preparation activities including clearing, grubbing, granular placement, and servicing of lots with municipal utilities and services. • The Notice of Determination was issued on November 17, 2023, and determined that the project is not likely to cause significant adverse environmental effects.	Point	2.5 kilometres
Attawapiskat First Nation - Airport Heights Residential Subdivision	No	Attawapiskat First Nation	Impact Assessment Ongoing	265.8	Attawapiskat First Nation	October 11, 2023	Unknown	Unknown	Yes -construction expected to overlap with Community Access Road construction	• Lot servicing project, for a maximum of 28 serviced residential lots in the proposed Airport Heights Residential Subdivision.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Musselwhite Mine	Yes	Southern shore of Opapimiskan Lake, approximately 480 kilometres north of Thunder Bay	Operations	273.5	Orla Mining Ltd.	April 1997	31 years	Mine expected to close in 2028, decommissioning period unknown	Yes - end of operations and decommissioning expected to overlap with Community Access Road construction	• Gold mine currently in operation. • Fly-in, fly-out operation on the southern shore of Opapimiskan Lake. • All-weather road connects Musselwhite Mine to the community of Pickle Lake. • Musselwhite property is 17.548 hectares, entirely on First Nations land. • Produced more than 4 million ounces of gold since April 1997. • The projected life of the mine has been extended from 2017 (the original estimated life of the mine) to approximately 2028 as additional mineral reserves have been confirmed by Orla Minning at the site.	Point	2.5 kilometres
Magino Mine	Yes	Wawa	Operating	307.0	Argonaut Gold	December 2012	Approximately 19 year mine life Decommissioning period anticipated 3 years, plus 10 years post-closure monitoring	Unknown	Yes - operations expected to overlap with Community Access Road construction	• Open-pit gold mine located in northern Ontario. • Includes mining of up to approximately 150 million tonnes of ore and approximately 430 million tonnes of mine rock.	Polygon	Not applicable
Island Gold Mine	Yes	Dubreuilville	Operating Expansion Phase 3+ in construction	307.2	Alamos Gold Inc	October 2007	Unknown	Anticipated 2026	Yes - Phase 1 operations expected to overlap with Community Access Road construction No - Phase 2 and 3 construction are not expected to overlap Community Access Road construction Yes - All operations expected to overlap with Community Access Road operations	• Gold mine located in northern Ontario. • Total mineable resources at 13.6 million tonnes. • Phase 1 expansion of operation completed in 2018. • Phase 2 was permitted in 2019, timing unknown. • Phase 3 announced in July 2020, timing unknown. • Phase 3+ announced in June 2022, timing unknown.	Polygon	Not applicable
Thunder Bay Airport Remedial Trial	No	Thunder Bay	Impact Assessment Ongoing	325.2	Transport Canada	January 1, 2024	Unknown	Unknown	Yes - construction expected to overlap with Community Access Road construction	• Remediation project at Thunder Bay Airport. • Includes the placement of 1 to 2 temporary containers (prefabricated sea containers or similar structures, approximately 12 metres by 3 metres in size) which will contain a remediation treatment unit, excavation of a trench (approximately 30 to 40 metres long) from which groundwater will be pumped and treated by the unit before the water is put back into the ground. • Associated works will include installation of electrical lines (approx. 1 kilometres) connecting the container to the existing power system, piping to connect the trench to the treatment unit, and a laydown area.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Michipicoten First Nation White Sands Creek Rehabilitation Project	No	Wawa, Ontario	Impact Assessment Ongoing	327.9	Michipicoten First Nation	August 3, 2023	Unknown	Unknown	Yes - construction expected to overlap with Community Access Road construction	• Rehabilitation and increasing the resiliency of an approximately 200-metre-long section of Whitesands creek, which flows through the centre of the Michipicoten First Nation Whitesands residential area and feeds directly into Lake Superior. • Aims to reduce Michipicoten First Nation's vulnerability in the case of a major water event, improve water quality, rehabilitate terrestrial and aquatic habitat, and increase citizen education and access to nature. • Includes the replacement of two culverts; stabilizing the stream bank with gabions and planting culturally / ecologically significant vegetation; and enhancing a public greenspace with the addition of a terrace and educational signage.	Point	2.5 kilometres
North Caribou Lake First Nation - Immediate Housing Lot Servicing	No	North Caribou Lake First Nation - Weagamow Lake	Impact Assessment Complete	348.6	North Caribou Lake First Nation	February 2, 2024	Unknown	Unknown	Yes -construction expected to overlap with Community Access Road construction	• Site servicing project at North Caribou First Nation. • Includes preliminary design and site development. • Includes site development includes geotechnical investigations, site surveying, clearing, grubbing, site grading and compaction, and extension of water / sewer lines to each lot. • Indigenous Services Canada issued its Notice of Determination on April 3, 2024, and determined that the project is not likely to cause significant adverse environmental effects.	Point	2.5 kilometres
North Caribou Lake First Nation Water Treatment System Upgrades	No	North Caribou Lake First Nation	Construction Tendering Ongoing	349.3	North Caribou Lake First Nation	August 28, 2023	Unknown	Unknown	Yes -construction expected to overlap with Community Access Road construction	• Water Treatment System Upgrades at North Caribou Lake First Nation. • Includes site preparation; construction of a new water treatment system, watermain and distribution network; decommissioning and demolition of the existing treatment plant; and construction of a truckfill structure; and site restoration. • Indigenous Services Canada issued the Notice of Determination and determined that the project is not likely to cause adverse environmental effects.	Point	2.5 kilometres
Weeneebayko Area Health Authority Redevelopment	No	Moosonee and Moose Factory Island	Ongoing	366.4	Ministry of Infrastructure	January 2022	Unknown	Unknown	Yes - expected construction to overlap with Community Access Road construction	• Construction of a new hospital, Elder Care Lodge, visitor hostel and staff accommodations in Moosonee and a new Ambulatory Care Centre on Moose Factory Island.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Goliath Gold Project	Yes	Dryden	Permitting ongoing	437.1	Treasury Metals Inc.	January 18, 2013	Unknown	Unknown	Yes - construction and operations expected to overlap with Community Access Road construction and operations	• Construction, operation, decommissioning and abandonment of an open-pit and underground gold mine. • Production capacity of 5,424 tonnes per day with a 12 year mine life.	Polygon	Not applicable
Springpole Lake Gold Project	Yes	Uchi Lake	Impact Assessment Ongoing	378.5	First Mining Gold Corp.	April 27, 2018	Based on Impact Assessment, operation is expected to be 12 years Decommissioning expected 6 years Post-closure monitoring period unknown	Unknown	Yes - construction and operations expected to overlap with Community Access Road construction and operations	• Impact assessment for the construction, operation, decommissioning and abandonment of an open-pit gold / silver mine and onsite metal mill. • Production capacity of 60,00 tonnes per day over an 11-year mine life. • Draft Environmental Impact Statement / Environmental Assessment materials were prepared and made available in April 2022.	Polygon	Not applicable
Crawford Nickel Project	Yes	34 kilometres north of Timmins, Ontario	Impact Assessment Ongoing	421.2	Canada Nickel Company	August 8, 2022	Operations expected for 43 years	Unknown	Yes - operations expected to overlap with Community Access Road construction and operations	• Construction, operation, decommissioning and abandonment of an open-pit nickel-cobalt mine and onsite metal mill. • Mine ore production capacity of 275,000 tonnes per day and a mill ore input capacity of 120,000 tonnes per day. • Operation is expected for approximately 43 years. • Operation is anticipated to begin in 2027.	Polygon	Not applicable
Hammond Reef Project	Yes	Atikokan	Permitting ongoing	388.8	Agnico Eagle Mines Limited	2027	14 Years (3 construction, 11 operations, closure to be determined)	Unknown	Yes - construction and operations expected to overlap with Community Access Road construction and operations	• Construction, operation and decommission of an open-pit gold mine. • Operational life of 11 years. • Includes two open pits, ore processing facility, tailings management facility, waste rock and water management facilities, 19 kilometres long 230 kilovolts transmission line, access road, and an onsite worker accommodation camp. • The Company requires additional federal and provincial permits to begin construction activities and with a 2.5-year construction timeline, the Hammond Reef Project could potentially be ready for production in 2027. • The project has not been approved by Agnico Eagle for development.	Polygon	Not applicable
Nuclear Waste Management Organization's Deep Geological Repository	No	Ignace, Ontario	Site selection ongoing	423.1	Nuclear Waste Management Organization	2010	Unknown	Unknown	Yes -if candidate location is chosen, then construction and operations expected to overlap with Community Access Road construction and operations	• Candidate location for the deep geological repository.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Pamour Mine	Yes	Timmins, Ontario	Operating	461.2	Newmont	1910	Operation expected until 2035, decommissioning period unknown	2035	Yes - operations expected to overlap with Community Access Road construction and operations	• Underground mine, open-pit, and stockpiles gold mine operation. • Associated locations: Broden and Hoyle Pond Underground. • November 2022 new water treatment plant constructed. • 60% of gold comes from Hyle Pond underground mine, remaining ore comes from Hollinger Open-Pit Mine.	Point	2.5 kilometres
Côté Gold Mine	Yes	Gogama	Operations	483.5	IAMGOLD Corp. / Sumitomo Metal Mining	May 3, 2013	Approximately 18 year mine life, decommissioning period unknown	Unknown	Yes - operations expected to overlap with Community Access Road construction and operations	• Construction, operation and rehabilitation of a new open-pit gold mine, covering approximately 1,050 hectares of land. • Processing will occur at a rate of approximately 36,000 tonnes per day. • Mining operations will be supported by the development of an explosives manufacturing and storage facility, maintenance garage, warehouse and administration complex. • Approximately 18 year mine life.	Polygon	Not applicable
Great Bear Gold Project	Yes	23 kilometres southeast of Red Lake, Ontario	Impact Assessment Pending	478.7	Kinross Gold Corporation	August 17, 2023	Mine life of approximately 25 years is expected Decommissioning period of 4 years, plus post-closure and monitoring period (timing unknown)	Unknown	Yes - operations expected to overlap with Community Access Road construction and operations	• Construction, operation, decommissioning and abandonment of a new open-pit and underground gold mine with an onsite metal mill. • Includes three open pits and is estimated to produce up to 60,000 tonnes per day, while the metal mill would process up to 15,000 tonnes of ore per day. • Operation is expected for approximately 20 years.	Polygon	Not applicable
Young-Davidson Mine	Yes	Matachewan, Ontario	Operating	526.7	Almos Gold Inc.	2012	25 years	Anticipated 2037	Yes - operations expected to overlap with Community Access Road construction and operations	• Underground gold mine near Matachewan, Ontario. • Multi-year expansion of the project completed in 2020.	Point	2.5 kilometres
Proposed Sault Ste. Marie Ferrochrome Production Facility	No	Sault Ste. Marie, Ontario	Site selection ongoing	492.5	Noront	2019	Construction approximately 5 to 10 years	Unknown	Yes - construction and operations expected to overlap with Community Access Road construction and operations	• Candidate location for proposed new ferrochrome processing plant in Sault Ste. Marie.	Point	2.5 kilometres
Separation Rapids	Yes	55 kilometres north of Kenora	Permitting ongoing	559.7	Avalon Advanced Materials Inc.	2026	Unknown	Unknown	Yes - construction and operations expected to overlap with Community Access Road construction and operations	• Lithium deposit in northern Ontario. • Anticipated target date for commencement of lithium concentrate production is early 2026.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Upper Beaver Gold Project	Yes	19 kilometres east of Kirkland Lake, Ontario	Impact Assessment Ongoing	567.6	Agnico Eagle Mines Ltd.	September 13, 2021	Unknown	Unknown	Yes - construction and operations expected to overlap with Community Access Road construction and operations	• Construction, operation, decommissioning and abandonment of an underground and open-pit gold and copper mine. • Includes onsite metal mill and structures for diverting water. • Maximum ore capacity is approximately 15,000 tonnes per day. • Mine life is approximately 16 years.	Polygon	Not applicable
Proposed Sudbury Ferrochrome Production Facility	No	Sudbury, Ontario	Site selection ongoing	608.1	Noront	2019	Construction approximately 5 to 10 years	Unknown	Yes - construction and operations expected to overlap with Community Access Road construction and operations	• Candidate location for proposed new ferrochrome processing plant in Sudbury.	Point	2.5 kilometres
Ogoki Forest Management Plans	Yes	Ogoki Forest, Ontario	Operating	Forest Management Plans: Varies Ogoki Primary Roads: 6.2 kilometres	GreenForest Management Inc. and Geraldton Area Natural Resources Advisory Committee	2020	10 years	2030	Yes - operations overlap with Community Access Road construction and operations	• Forest Management Plans for the Ogoki Forest. • Includes Ogoki-Armstrong Primary Roads as these roads are being used for forest management. • Includes plans for future harvest. • Ogoki Forest is approximately 10,900 square kilometres in size and includes approximately 9,798 square kilometres of forested area. • Majority of the forest is Crown land and is subject to forest management planning and forest management operations.	Polygon	100 metres
KWG Railway Project	No	James Bay Lowlands	Unknown	Unknown	KWG Resources Spider Resources	2009	Unknown	Unknown	No - assumed no overlap as status of this project is not known.	• Approximately 350-kilometre rail link from Nakina, Ontario to the Ring of Fire mines. • Exact alignment and location of proposed railway is not known at the time of preparation of this Cumulative Effects Assessment, therefore this project is not shown on the Inclusions List Map.	Not applicable	Not applicable
Neskantaga First Nation Community Recreation Centre	No	Neskantaga First Nation	Impact Assessment ongoing	110.9	Neskantaga First Nation	2008	Unknown	Unknown	No - no expected overlap	• Renovation of the existing community recreation centre and arena, to include an additional 2,400 square feet in size and will include washrooms.	Point	2.5 kilometres
Little Jackfish River Hydroelectric Project	No	Little Jackfish River watershed	Impact Assessment on hold	124.2	Ontario Power Generation	2009	Unknown	On hold	No - overlap not anticipated as project is on hold	• Development of approximately 100 megawatts of renewable hydroelectric power through the construction of two generating stations on the Little Jackfish River. • The location of the Proposed Undertaking is shown on the map, and the anticipated zone of influence is within the Little Jackfish River watershed. Each generating station will include a dam with a water intake and bypass structures, powerhouse and tailrace channel. Associated facilities include access roads and a large temporary construction camp. • Project has been on hold since 2015.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Rehabilitation of Nibinamik Lagoon Sewage Treatment Lagoon and Collection Systems	Yes	Nibinamik First Nation	Construction	173.1	Nibinamik First Nation	2022	2 years	2024	No - no expected overlap	• Repair and replacement of components of a sewage lagoon and the purchase of a septic truck in Nibinamik First Nation • Includes re-excavating and repairing 30 manholes and covers, flushing outflow lines, removing and replacing 2 pressure relief values, repairing damaged section of the lagoon and buying a septic truck.	Point	2.5 kilometres
Ginoogaming KM 132 Bridge Replacement	No	Ginoogaming First Nation	Construction Tendering Ongoing	194.7	Ginoogaming First Nation	August 23, 2023	Approximately 2 years	October 15, 2025	No - no expected overlap	• Replacement of the Bridge located on Caltonite known as kilometres 132 bridge in Ginoogaming First Nation • Indigenous Services Canada issued its Notice of Determination on October 27, 2023, and determined that the project is not likely to cause significant adverse environmental effects.	Point	2.5 kilometres
New Osnaburgh Water Treatment Plant Upgrades	No	New Osnaburgh, Ontario	Impact Assessment complete	242.2	Mishkeegogamang First Nation	March 1, 2021	Unknown	Unknown	No - no expected overlap	• Upgrade the existing water treatment plant, extend the water distribution system to planned lot developments as well as un-serviced homes, improve the reservoir for better fire flows and increased fire protection. • Infrastructure Canada issued its Notice of Determination on October 16, 2023, and determined that the project is not likely to cause significant adverse environmental effects.	Point	2.5 kilometres
Thierry Copper Nickel Mine	Yes	Pickle Lake	Unknown	251.0	Canadian Critical Minerals Inc	Unknown	Unknown	Uknown	No - not applicable	• Copper and nickel mine located 15 kilometres west of Pickle Lake. • Property is approximately 4,700 hectares in size. • Project cannot be assessed as reasonably foreseeable activities in the Cumulative Effects Assessment as plans for future development have not been disclosed at the time of preparing the Environmental Assessment / Impact Statement.	Point	2.5 kilometres
Repairs and Upgrades to Sewage Lagoon Attawapiskat First Nation	No	Attawapiskat First Nation	Uknown	267.8	Unknown	Unknown	Unknown	Unknown	No - not applicable	• Project cannot be assessed as reasonably foreseeable activities in the Cumulative Effects Assessment as plans for future development have not been disclosed at the time of preparing the Environmental Assessment / Impact Statement.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Rehabilitation of the Whitefish Bay Water Distribution System	No	Lac Seul First Nation	Impact Assessment Complete	268.1	Lac Seul First Nation	August 8, 2022	Unknown	Unknown	No - no expected overlap	• Replacement of aged and undersized watermain in Lac Seul First Nation to meet current water demands and fire protection, in accordance with current regulations and standards. • Includes the replacement of the aged and undersized 50 millimetres watermain, with the properly sized 150 millimetres watermain, replacement of the aged an undersized and waterline (lake crossing), reconnection of existing water services to existing homes and buildings; and supply and installation of two upgraded high lift pumps. • Infrastructure Canada issued a Notice of Determination on January 29, 2024, and has determined the proposed Rehabilitation of the project is not likely to cause significant adverse environmental effects.	Point	2.5 kilometres
Kapuskasing River Waterpower Projects	No	Kapuskasing, Ontario	Impact Assessment on Hold	Clouston Rapids: 359.2 Cedar Rapids: 344.5 Buchan Falls: 349.0	Xeneca Power Development Inc	2009	Unknown	On hold	No - overlap not anticipated as project is on hold	• Environmental evaluation and assessment for three proposed Generating Stations located at Buchan Falls, Middle Township Buchan (Clouston Rapids) and at Near North Boundary (Cedar Rapids). • Each site is located on the Kapuskasing River, between the community of Elsas and the Town of Kapuskasing. • The proposed waterpower generating stations on the Kapuskasing River will generate clean and renewable energy at a total installed capacity of about 19.45 megawatts. Each station will have a water control structure (spillway and earthfill dams) with attached powerhouse (with the exception of Outlet Kapuskasing Lake which will have a spillway dam and an open approach channel to the powerhouse). • New roads and possible upgrades of existing roads will be required to access the sites. Transmission lines connecting at Weston Lake Transmission Station / Distribution Station and / or Kapuskasing Transmission Station will be installed to connect the stations to the provincial power grid. • Project has been on hold since 2014.	Point	2.5 kilometres
Sewage Pumping Station Rehabilitation	No	Weenusk First Nation	Construction	355.8	Weenusk First Nation	2022	2 years	March 2024	No - no expected overlap	• Replacement of pumps, panel and level floats; installing provisions for auto dialer; replacing guide rails and piping; replacing wooden manhole; installing access ladder; installing standby fixed generator; and associated electrical work.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Moose Cree First Nation Water Treatment Plant	No	Moose Cree First Nation (Ontario)	Impact Assessment ongoing	363.7	Moose Cree First Nation (Ontario)	Unknown	Unknown	Anticipated November 2024	No - no expected overlap, project will be complete prior to Community Access Road construction	• Proposed water treatment plant at Moose Cree First Nation, 1,435 square metres in size. • Includes a water treatment system and distribution piping. • The project includes construction over top of a below ground concrete reservoir, installation of a new raw water intake pipe into the Moose River, fish screen, raw water pumping chamber, new watermain and service piping, housing development on the northeast side of the community.	Point	2.5 kilometres
Pigeon River Drilled Well Groundwater Supply	No	Canadian Border Services Agency Pigeon River	Impact Assessment Complete	369.1	Canada Border Services Agency	February 14, 2024	Unknown	Unknown	No - no expected overlap	• Design and construct for two new 15,000 litre potable water tanks (to be installed underground) for purposes of supplying potable water to the facility. Provide new waterproof tub and isolated lid, as well as new culvert complete with hinged and locking cover. • Connect potable water piping complete with insulation, heat trace, isolation valving and check valves though tub wall and route piping through trench to existing water treatment building in close proximity. • Excavation required to native subgrade and backfill using excavated fill and clear stone as required to provide 3:1 grading to native subgrade, finished with topsoil and sod. • Includes re-configuring the existing cistern for firefighting water use. • The Canada Border Services Agency issued its Notice of Determination on February 14, 2024, and determined that the project is not likely to cause significant adverse environmental effects.	Point	2.5 kilometres
Ivanhoe River Waterpower Project	No	Chapleau, Ontario	Impact Assessment on hold	Three Falls: 383.9 Chute: 394.1	Xeneca Power Development Inc.	2009	Unknown	On hold	No - overlap not anticipated as project is on hold	• Environmental evaluation and assessment on two proposed Generating Stations located on the Ivanhoe River, in Montcalm and Bedford Townships, north of the town of Foleyet. • The proposed waterpower generating stations will generate clean, green, renewable energy at a total installed capacity of about 8.7 megawatts. Each station will have a water control structure (spillway dam) with attached powerhouse. • Upgrades of existing forestry roads will be required to access the sites. A transmission line connecting at Weston Lake Distribution Station will be installed to connect the stations to the provincial power grid. • Project has been on hold since 2014.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Lac Seul First Nation Burial Site Mapping	No	Lac Seul First Nation	Impact Assessment ongoing	401.1	Lac Seul First Nation	August 4, 2024	Unknown	Unknown	No - no expected overlap	• Shoreline erosion protection project for five traditional burial grounds along the banks of the Lost Lake and Lac Seul.	Point	2.5 kilometres
Fort Severn Modular Bridge	No	Fort Severn Remote Northern Airport	Design upcoming	471.1	Ministry of Transportation	2023	Approximately 3 years	2025 to 2026	No - no expected overlap	• Bridge replacement at Fort Severn Remote Northern Airport.	Point	2.5 kilometres
Sandy Lake Cultural Area	No	Sandy Lake First Nation	Design ongoing	478.3	Sandy Lake First Nation	April 5, 2023	Unknown	Unknown	No - no expected overlap	• New cultural area including an outdoor celebration area with seating for 250 people, traditional fireplaces, women's longhouses, and seating areas at Sandy Lake First Nation. • The area will be adjacent to Sandy Lake, and docks will be added to promote traditional fishing. • Crown-Indigenous Relations and Northern Affairs Canada issued its Notice of Determination and determined that the project is not likely to cause significant adverse environmental effects.	Point	2.5 kilometres
Sandy Lake First Nation - Child and Family Services Building	No	Sandy Lake First Nation	Impact Assessment ongoing	478.6	Sandy Lake First Nation	July 25, 2023	Unknown	Unknown	No - no expected overlap	• Construction of a Child and Family Services Building Project at Sandy Lake First Nation. • Building will be approximately 1,900 square metres footprint, serviced with electricity, water / wastewater systems, internet. • Includes a parking lot, and appropriate drainage ditching.	Point	2.5 kilometres
Bateman Gold	Yes	Red Lake	Unknown	488.0	Evolution Mining	Unknown	Unknown	Unknown	No - not applicable	• Gold deposit located in northern Ontario. • Project includes a commissioned shaft and significant underground development, 1,250 tonne per day mill facility, tailings management facility, electric power supple and substation, and 200-person camp. • Project cannot be assessed as reasonably foreseeable activities in the Cumulative Effects Assessment as plans for future development have not been disclosed at the time of preparing the Environmental Assessment / Impact Statement.	Point	2.5 kilometres
Chukuni River Bridge Replacement	No	Balmertown, Red Lake, Ontario	Preliminary Design	490.6	Ministry of Transportation	2021	Approximately 5 years	2025 to 2026	No - no expected overlap	• Bridge replacement at Chukuni River, 4 kilometres south of Highway 105	Point	2.5 kilometres
Hwy 618 Reconstruction and Rehabilitation	No	Northwestern Ontario	Planning / Environmental Assessment upcoming	494.9	Ministry of Transportation	2023	Approximately 3 years	2025 to 2026	No - no expected overlap	• Reconstruction and rehabilitation of Highway 618 southerly, towards Red Lake, Ontario.	Line	100 metres
Western James Bay and Southwestern Hudson Bay National Marine Conservation Area	No	James Bay Region, Ontario	Ongoing	277.2	Mushkegowuk Council and Parks Canada	Unknown	Unknown	Unknown	No - no expected overlap	• Proposed National Marine Conservation Area in the James Bay and Hudson Bay Marine Regions. • Project is currently assessing the feasibility of a National Marine Conservation Area.	Polygon	Not applicable

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Waasigan Transmission Line Project - Route 1	No	Thunder Bay to Dryden, Ontario	Impact Assessment ongoing	305.5	Hydro One	2019	Unknown	Unknown	No - no expected overlap	• Proposed new double-circuit 230 kilovolt transmission line between the Lakehead Transformer Station in the Municipality of Shuniah and the Mackenzie Transformer Station in the Town of Atikokan • A new single-circuit 230 kilovolts transmission line between the Mackenzie Transformer Station and the Dryden Transformer Station in the City of Dryden.	Line	100 metres
Backcountry Paddling Site Upgrades	No	Pukaskwa National Park	In progress	233.5	Parks Canada	March 5, 2024	Unknown	Unknown	No - no expected overlap	• Upgrade five existing backcountry paddling campsites along the Lake Superior coastline. • Upgrades will include a new bear-proof food locker, a new pit-privy, and access trails from the existing campsite to the new infrastructure.	Point	2.5 kilometres
Dona Lake Gold Project	No	Pickle Lake	Ongoing	231.4	Metals Creek Resources Corp	Unknown	Unknown	Unknown	No - not applicable.	• Gold Mine near Pickle Lake, Ontario. • Project cannot be assessed as reasonably foreseeable activities in the Cumulative Effects Assessment as plans for future development have not been disclosed at the time of preparing the Environmental Assessment / Impact Statement.	Point	2.5 kilometres
Black Bird Deposit	Yes	James Bay Lowlands	Not Active	97.3	Wyloo	Not applicable	Not applicable	Not applicable	Not applicable	• Chromite deposit in the James Bay Lowlands area, as part of the McFaulds Lake project. • Approximately 23.5 million tonnes of chromite. • Project cannot be assessed as reasonably foreseeable activities in the Cumulative Effects Assessment as plans for future development have not been disclosed at the time of preparing the Environmental Assessment / Impact Statement. • Not included in the Cumulative Effects Assessment as it is a deposit and not currently an active project.	Point	2.5 kilometres
Junior Lake Project	Yes	85 kilometres north of Beardmore	Not Active	98.2	Landore Resources Limited	Not applicable	Not applicable	Not applicable	Not applicable	• Consists of approximately 30,507 hectares of property, containing a number of precious metal deposits including deposits for gold, nickel, copper, cobalt, platinum, and palladium. • Not included in the Cumulative Effects Assessment as it is a deposit and not an active project.	Point	2.5 kilometres

Project	Identified in Tailored Impact Statement Guidelines (Yes / No)	Location	Status	Distance (kilometres) and Direction from Community Access Road Study Area	Developer / Company	Project Start Date	Project Duration	Project Completion Date	Assumed Temporal Overlap with Community Access Road Activities (Yes / No)	Project Description	Map Feature Type	Map Buffer
Big Daddy Deposit	Yes	James Bay Lowlands	Not Active	100.5	Wyloo	Not applicable	Not applicable	Not applicable	Not applicable	• Open-pit mine, crushing plant, site infrastructure, railway and power line to a chromite deposit in the James Bay Lowlands area, as part of the McFaulds Lake project. • Approximately 38 million tonnes of resources. • Project cannot be assessed as reasonably foreseeable activities in the Cumulative Effects Assessment as plans for future development have not been disclosed at the time of preparing the Environmental Assessment / Impact Statement. Not included in the Cumulative Effects Assessment as it is a deposit and not currently an active project.	Point	2.5 kilometres
Black Label Deposit	Yes	James Bay Lowlands	Not Active	103.6	Wyloo	Not applicable	Not applicable	Not applicable	Not applicable	• Chromite deposit in the James Bay Lowlands area, as part of the McFaulds Lake project. • Approximately 5.40 million tonnes of resources. • Project cannot be assessed as reasonably foreseeable activities in the Cumulative Effects Assessment as plans for future development have not been disclosed at the time of preparing the Environmental Assessment / Impact Statement. • Not included in the Cumulative Effects Assessment as it is a deposit and not currently an active project.	Point	2.5 kilometres
Black Thor Deposit	Yes	James Bay Lowlands	Not Active	103.6	Wyloo	Not applicable	Not applicable	Not applicable	Not applicable	• Chromite deposit located on the edges of James Bay Lowlands, as part of the McFaulds Lake project. • Approximately 137.70 million tonnes of resources. • Expected to have a lifespan of 30 years or greater. • Project cannot be assessed as reasonably foreseeable activities in the Cumulative Effects Assessment as plans for future development have not been disclosed at the time of preparing the Environmental Assessment / Impact Statement. • Not included in the Cumulative Effects Assessment as it is a deposit and not currently an active project.	Point	2.5 kilometres

Assumptions: - Information and projects presented in this table represent the information publicly available at the time the Cumulative Effects Assessment was completed.
- Construction of the Community Access Road is anticipated to start within 2 to 5 years of Environmental Assessment approval, depending on funding and permit acquisition.
- Construction of the Community Access Road duration is anticipated to be 10 years.

Definitions: **Project Start Date:** Date that the Environmental Assessment or other permitting processes for the project started. Where information was available on the Impact Assessment Agency of Canada website, start date and Notice of Determination date and recommendations is included.

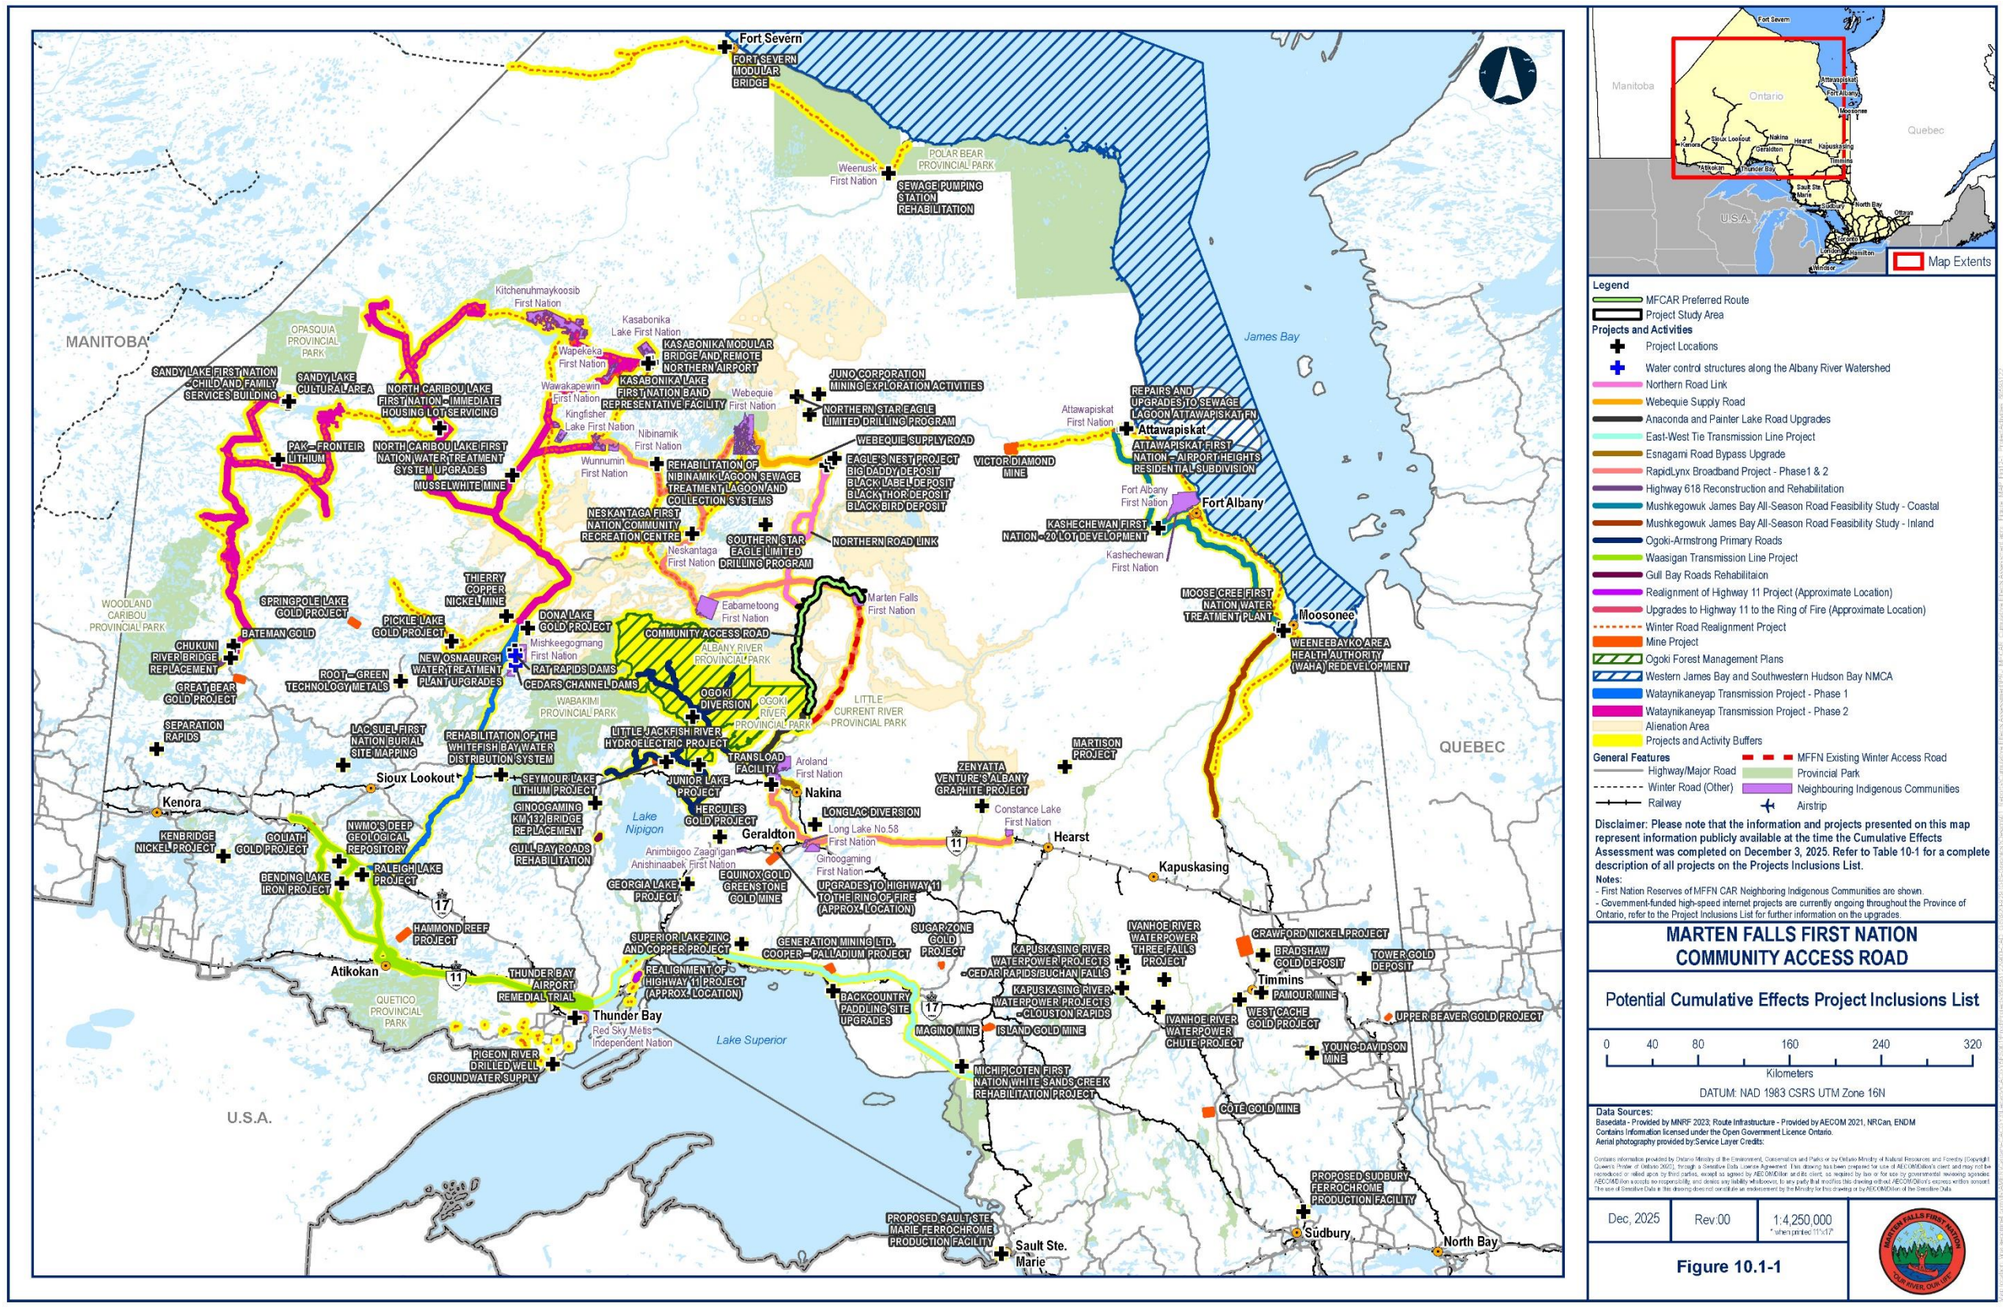
Project Duration: Amount of time (years) project activities will take place. Where information was available and applicable, duration of each project phase is noted.

Project Completion Date: Date all activIities for the project will be completed. Completion date varies depending on type of project; bridge or highway updates completion date reflects when construction of the project is complete, and mining projects completion date reflects when the decommissioning and rehabilitation activities are complete / mine is abandoned.

Assumed Temporal Overlap with Community Access Road Activities: The phases each project is anticipated to overlap with the Community Access Road. Overlap is assumed based on the information provided in the Project Start Date, Project Duration and Project Completion Date columns.

Ongoing: Active project work is taking place; project is active at the time of preparation of this table. Where available, information on specific work that is ongoing for the project has been included.

Unknown: Information or project details were not publicly available, or it was not possible to determine the required details based on the information available at the time of preparation of this table.



On Hold: Project has been put on pause for various reasons, currently no active project work.

Not Active / Not Applicable: Applies to non-active projects and are not included as part of the Cumulative Effects Assessment (locations of First Nations communities, mineral deposits, and so forth).

Operation: Construction is complete on the project and project is currently in use / active.

Decommissioning / Rehabilitation: Applies to mining projects only. Refers to activities following operations to rehabilitate the land.

Figure 10.1-1: Potential Cumulative Effects Project Inclusions List

10.2 Water

10.2.1 Scoping

Where residual effects identified in **Section 9** were of negligible magnitude, unlikely or possible to occur, or positive in direction, the effect was not carried forward into the Cumulative Effects Assessment. The valued components with residual effects that have been carried forward for the Cumulative Effects Assessment for water disciplines are described in **Table 10.2-1**.

To determine the spatial boundaries of potential cumulative effects, the projects listed in **Table 10.2-2** were considered for the Cumulative Effects Assessment. The remainder of the projects on the Project Inclusions List were determined to have no spatial or temporal overlap with water disciplines study areas; therefore, they were not considered as part of the Cumulative Effects Assessment.

Table 10.2-1: Valued Components Carried Forward and Corresponding Spatial and Temporal Boundary for Water Disciplines

Discipline	Valued Component	Spatial Boundary	Temporal Boundary
• **Surface Water**	• Surface Water Quantity • Surface Water Quality • Sediment Quality	• Includes the three tertiary watersheds (4GD Upper Albany - Makokibatan, 4GE Lower Ogoki, and 4GF Upper Albany - Muswabik) that are intersected by the centreline of the Preferred Route. • The Regional Study Area was extended to include areas where the Local Study Area falls outside of these tertiary watersheds. Tertiary watersheds are based on the federal “Drainage Area” reporting framework and represent third level subdivisions of Canada into suitably sized areas based on drainage for administrative purposes (Ministry of Natural Resources and Forestry, 2015).	• Construction
• **Fish and Fish Habitat**	• Lake Sturgeon, Walleye, Brook Trout, Northern Pike, Lake Whitefish, and Burbot	• Includes the three tertiary watersheds (4GD Upper Albany - Makokibatan, 4GE Lower Ogoki, and 4GF Upper Albany - Muswabik) that are intersected by the centreline of the Preferred Route. • The Regional Study Area was extended to include areas where the Local Study Area falls outside of these tertiary watersheds. Tertiary watersheds are based on the federal “Drainage Area” reporting framework and represent third level subdivisions of Canada into suitably sized areas based on drainage for administrative purposes (Ministry of Natural Resources and Forestry, 2015).	• Construction • Operations
• **Groundwater and Geochemistry**	• Groundwater	• 2.5 kilometres from centreline of the Preferred Route and associated construction areas.	• Construction • Operations
• **Peatlands**	• Direct peatland loss • Changes to groundwater • Fragmentation and edge effects • Fugitive dust emissions	• Includes quaternary watersheds that overlap with the peatlands existing conditions Local Study Area.	• Construction • Operations

Table 10.2-2: Project and Physical Activities Carried Forward for Water Disciplines

Discipline(s)	Project	Project Description	Project / Activity Reasonably Foreseeable (Yes / No)	Valued Components Temporal Overlap with Project (Yes / No)	Valued Components Spatial Overlap with Project (Yes / No)
• **Surface Water** • **Fish and Fish Habitat** • **Groundwater and Geochemistry** • **Peatlands**	• Northern Road Link	• Marten Falls First Nation and Webequie First Nation are proposing to build, operate and maintain an all-season multi-use road and associated infrastructure between the Community Access Road that has been proposed by Marten Falls First Nation and the supply road that has been proposed by Webequie First Nation. • Terms of Reference for the preparation of an Environmental Assessment were approved March 3, 2023.	• Yes	• Yes	• Local Study Area - Yes • Regional Study Area - Yes
• **Surface Water** • **Fish and Fish Habitat** • **Groundwater and Geochemistry** • **Peatlands**	• Anaconda and Painter Lake Forestry Access Road Upgrades	• Upgrades to existing road will be required for heavy vehicles accessing the Community Access Road route during construction and operations. • Currently discussions on proponency and scope of work are underway. • Potential scope of work is expected to include roadway widening, culvert and bridge replacements / rehabilitations to accommodate higher weight vehicles, and road base improvements. • This project will be completed prior to the start of the construction of the Community Access Road; therefore, the upgrade to these roads is not expected to overlap with the construction of the Community Access Road.	• Yes	• Yes	• Local Study Area - Yes • Regional Study Area - Yes
• **Surface Water** • **Fish and Fish Habitat** • **Groundwater and Geochemistry** • **Peatlands**	• Rapid Lynx Broadband	• Approximately 810 kilometres of fibre-optic cables, providing reliable high-speed internet service to five Matawa First Nation communities: Eabametoong, Marten Falls, Neskantaga, Nibinamik, and Webequie with an interconnection at Aroland.	• Yes	• Yes	• Local Study Area - Yes • Regional Study Area - Yes
• **Surface Water** • **Fish and Fish Habitat** • **Peatlands**	• Ogoki Forest Management Plans	• Forest Management Plans for the Ogoki Forest. • Includes Ogoki-Armstrong Primary Roads as these roads are being used for forest management. • Includes plans for future harvest. • Ogoki Forest is approximately 10,900 square kilometres in size and includes approximately 9,798 square kilometres of forested area. • Majority of the forest is traditional territory and is subject to forest management planning and forest management operations.	• Yes	• Yes	• Local Study Area - Yes • Regional Study Area - Yes
• **Surface Water** • **Fish and Fish Habitat**	• Winter Access Road Realignment Project	• Funding to remote northern communities for projects involving installation of water crossing infrastructure, such as pre-engineered bridges and culverts, and repairs to existing structures. • Funding for approximately 3,200 kilometres of winter access roads in Northern Ontario.	• Yes	• Yes	• Local Study Area - Yes • Regional Study Area - Yes

10.2.2 Surface Water

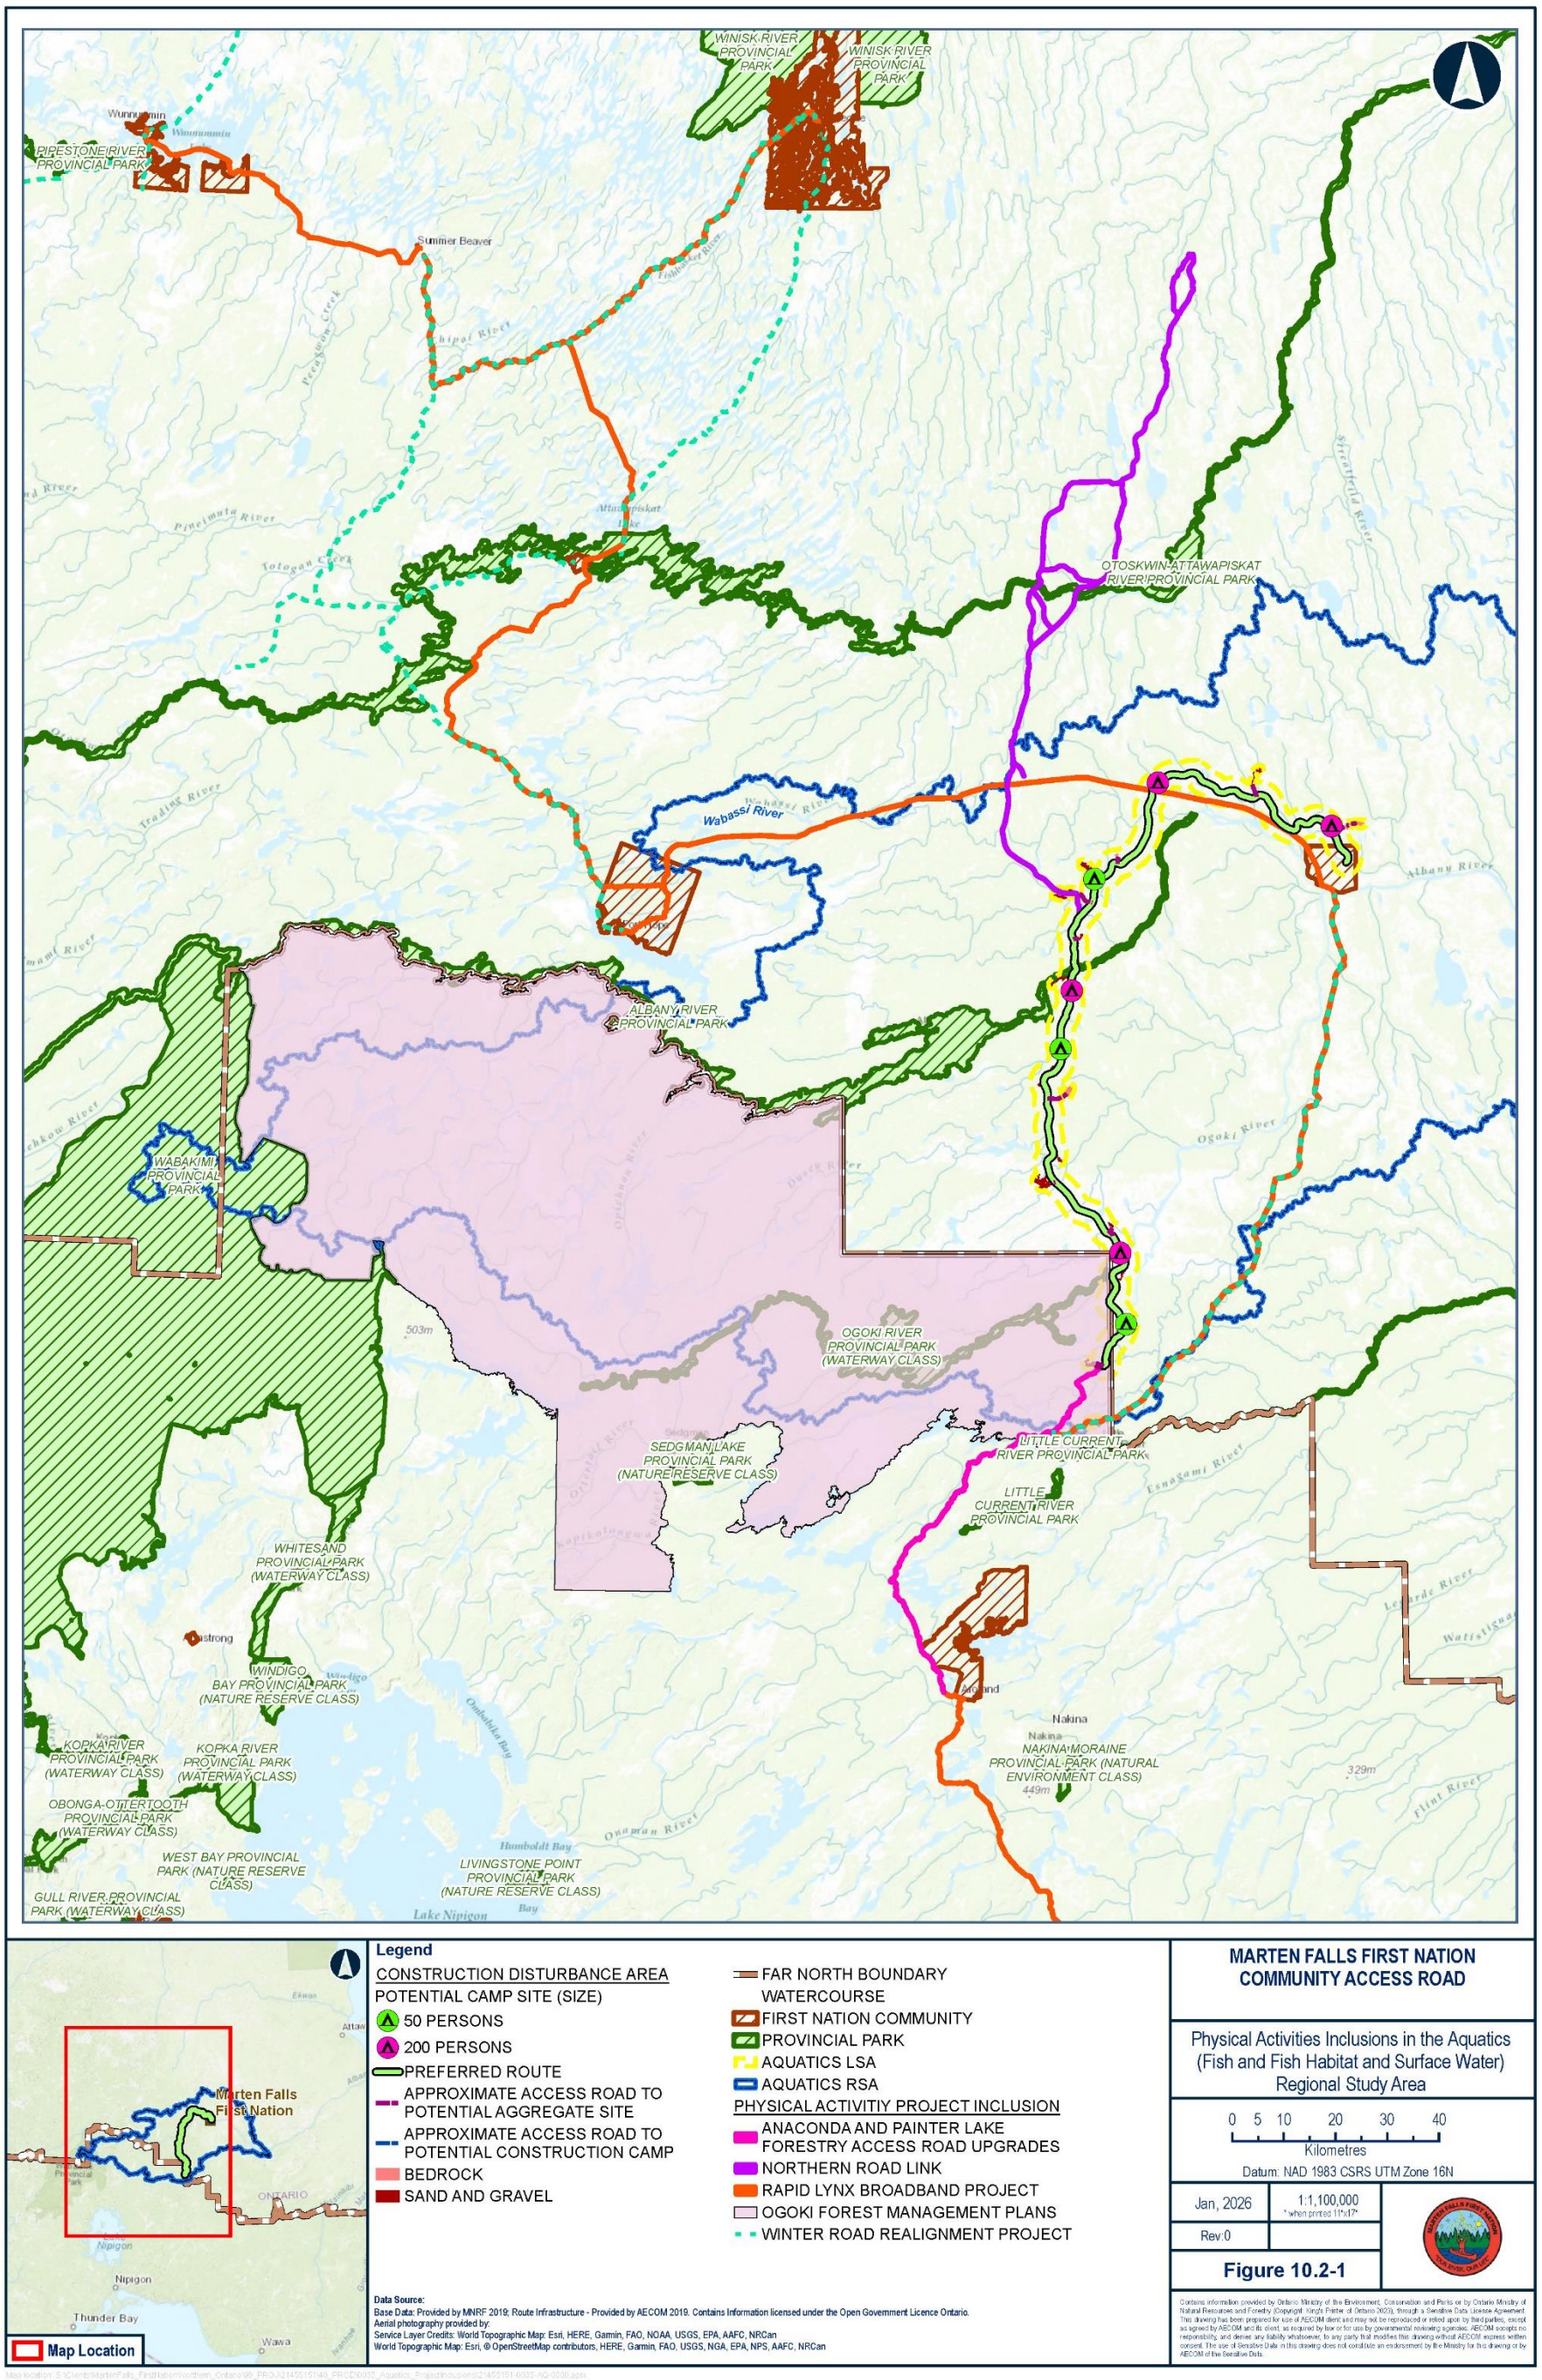
Three valued components with residual effects were carried forward to the Cumulative Effects Assessment:

- Surface water quantity;
- Surface water quality; and
- Sediment quality.

The locations of the projects considered for the Cumulative Effects Assessment in relation to the surface water Regional Study Area are shown on **Figure 10.2-1**.

10.2.2.1 Surface Water Quantity

The Northern Road Link and Rapid Lynx Broadband project, along with the Community Access Road, have the potential for cumulative effects on surface water quantity from short-term water taking and discharges during construction. No road construction is expected as part of the Rapid Lynx Broadband project, but water-taking activities as part of that project may still be required for drilling activities.



Short-term water takings during construction of the Community Access Road may affect surface water quantity including reductions in streamflows and / or water levels at nearby waterbodies, which are also crossed by the Northern Road Link (Gourlie Creek and Wabassi River).

Cumulative effects from short-term water takings and discharges have the potential to occur because work conducted at the same two crossing locations that are spatially close to one another as part of the Community Access Road and the Northern Road Link. However, the effects from each project for short-term water takings for the purpose of construction would be expected to be localized to the selected water-taking locations (for example, surface water locations) and to result in minimal change to overall surface water quantity reporting back into the receiving systems.

10.2.2.2 Surface Water Quality

Impacts to surface water quality (increase to the concentrations of suspended solids and chemical constituents in receiving waterbodies) are predicted to occur as a result of short-term water discharges or diversions, and wash-off of organic debris to nearby waterbodies, and / or increased rates of erosion in disturbed and exposed areas with sediment transport and delivery to adjacent waterbodies during construction of the Community Access Road and the Northern Road Link.

Figure 10.2-1: Physical Activities Inclusions in the Aquatics (Fish and Fish Habitat and Surface Water) Regional Study Area

Cumulative effects from short-term discharges have the potential to occur because work may be conducted at water crossing locations where the Community Access Road and Northern Road Link overlap spatially; however, are expected to be localized to the selected water-taking locations (for example, surface water locations) and to result in minimal change to overall surface water quality reporting back into the receiving systems.

The use of short-term water diversions to create and maintain a dewatered area to support installation of temporary and permanent waterbody crossings and removal of temporary waterbody crossing structures, may result in a measurable increase or reduction in streamflows, water levels, and erosion sedimentation processes at discrete locations upstream or downstream of the waterbody crossing. This has the potential to result in an increase to the concentrations of suspended solids and chemical constituents in waterbodies during these short-term water diversions. However, these impacts are also localized to crossing locations and construction areas.

10.2.2.3 Sediment Quality

The construction of the Northern Road Link and Rapid Lynx Broadband project, along with the Community Access Road, have the potential for cumulative effects on sediment quality from the wash-off of organic debris to nearby waterbodies, and / or increased rates of erosion in disturbed and exposed areas with sediment transport and delivery to adjacent waterbodies during construction.

Measurable changes to sediment quality may occur as part of site preparation, earthworks, and / or stockpiling activities as part of the Northern Road Link, Rapid Lynx Broadband and the Community Access Road; however, the predicted cumulative effects are negligible and are not anticipated to be greater than the predicted residual effects.

10.2.2.4 Mitigation Measures

It is anticipated that mitigation and enhancement measures will be, or have been, implemented to limit the effects of short-term water takings during the construction of the Northern Road Link and Rapid Lynx Broadband project and that these mitigation and enhancement measures will be similar to those implemented for the Community Access Road. Refer to **Section 9.3.2** for a complete description of the proposed mitigation measures for surface water.

As a best practice, it is suggested that monitoring programs of the Community Access Road for existing and future physical activities / project works share relevant monitoring data for areas where predicted effects may overlap, as well as share the timing of such

construction activities. Additional timing and monitoring data of related works, such as short-term water takings or discharges, should be shared between projects as these potential impacts to surface water quantity, surface water quality and sediment quality could lead to compounding cumulative effects if the works occur during the same construction periods in the same spatial overlapping project areas.

10.2.2.5 Determination of Significance

Significance was determined only for disciplines where it was required to meet federal or provincial requirements. For the purposes of this Cumulative Effects Assessment, significance of the effects for surface water was not determined.

10.2.3 Fish and Fish Habitat

Two valued components with residual effects were carried forward to the Cumulative Effects Assessment:

- Changes to fish habitat quantity and quality through physical alteration of waterbodies where work is below the high-water mark; and
- Changes to fish survival and reproduction from improved public access to recreational angling areas.

The locations of the projects considered for the Cumulative Effects Assessment in relation to the fish and fish habitat Regional Study Area are shown on **Figure 10.2-1**.

10.2.3.1 Fish Habitat Quantity and Quality

Direct habitat effects can include alteration or loss of specific habitat features, such as pools, aquatic vegetation, and bed materials that ultimately lead to loss or impairment of habitat functions, including overwintering, spawning, and rearing habitat for fish or lower trophic levels. These direct habitat effects may result in changes in the food supply, which may be reflected in altered fish community structure and productivity.

The effects from Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, Rapid Lynx Broadband, and Winter Access Road Realignment projects on fish habitat quantity and quality from physical alterations would be expected to be localized to crossing locations and have limited potential for cumulative effects on the populations of valued component fish species.

Habitat of the valued component fish species (Lake Sturgeon, Walleye, Brook Trout, Northern Pike, Lake Whitefish, and Burbot) is anticipated to remain stable and

functional, but there may be a minor decrease in productivity from physical alteration of the waterbodies. However, the valued component fish species populations are anticipated to remain self-sustaining and ecologically effective.

10.2.3.2 Fish Habitat Survival and Reproduction

Improved public access to recreational angling areas from construction and operations of the Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades can affect fish survival and reproduction by increasing harvest pressure from recreational anglers, small communities close to the Community Access Road, construction workers while onsite, and increased introduction or spread of invasive species and pathogens from the increased access and harvest pressure. However, the region will remain relatively remote with the nearest urban centre (Thunder Bay) being over 430 kilometres from Marten Falls, and a large influx of recreational anglers is not expected. The Winter Access Road Realignment Project involves upgrades to the existing winter access road, and as such, would not change the existing access to the area.

Northern Road Link and Rapid Lynx Broadband project include crossings that are on the same waterbodies as the Community Access Road (Wabassi River, Buffaloskin River, Albany River, Gourlie Creek, and two unnamed waterbodies). Due to the distance separating the crossings on the Wabassi and Albany rivers, these likely involve different fish populations and any effects on valued component fish populations related to fish harvest at these locations would not be expected to overlap cumulatively. For the Buffaloskin River, Gourlie Creek, and the two unnamed waterbodies, a substantial increase in harvest pressure would not be expected due to the remoteness of the sites as it would likely remain the same local fishers who would access these locations currently.

Although the Anaconda and Painter Lake Forestry Access Road upgrades will provide access to the south end of the Community Access Road in the Lower Ogoki watershed, there are no waterbodies on the Anaconda and Painter Lake Forestry Access Road that are also crossed by the Community Access Road, and therefore are not expected to interact cumulatively with the Community Access Road to increase fish harvest beyond what has already been predicted for the Community Access Road.

10.2.3.3 Mitigation Measures

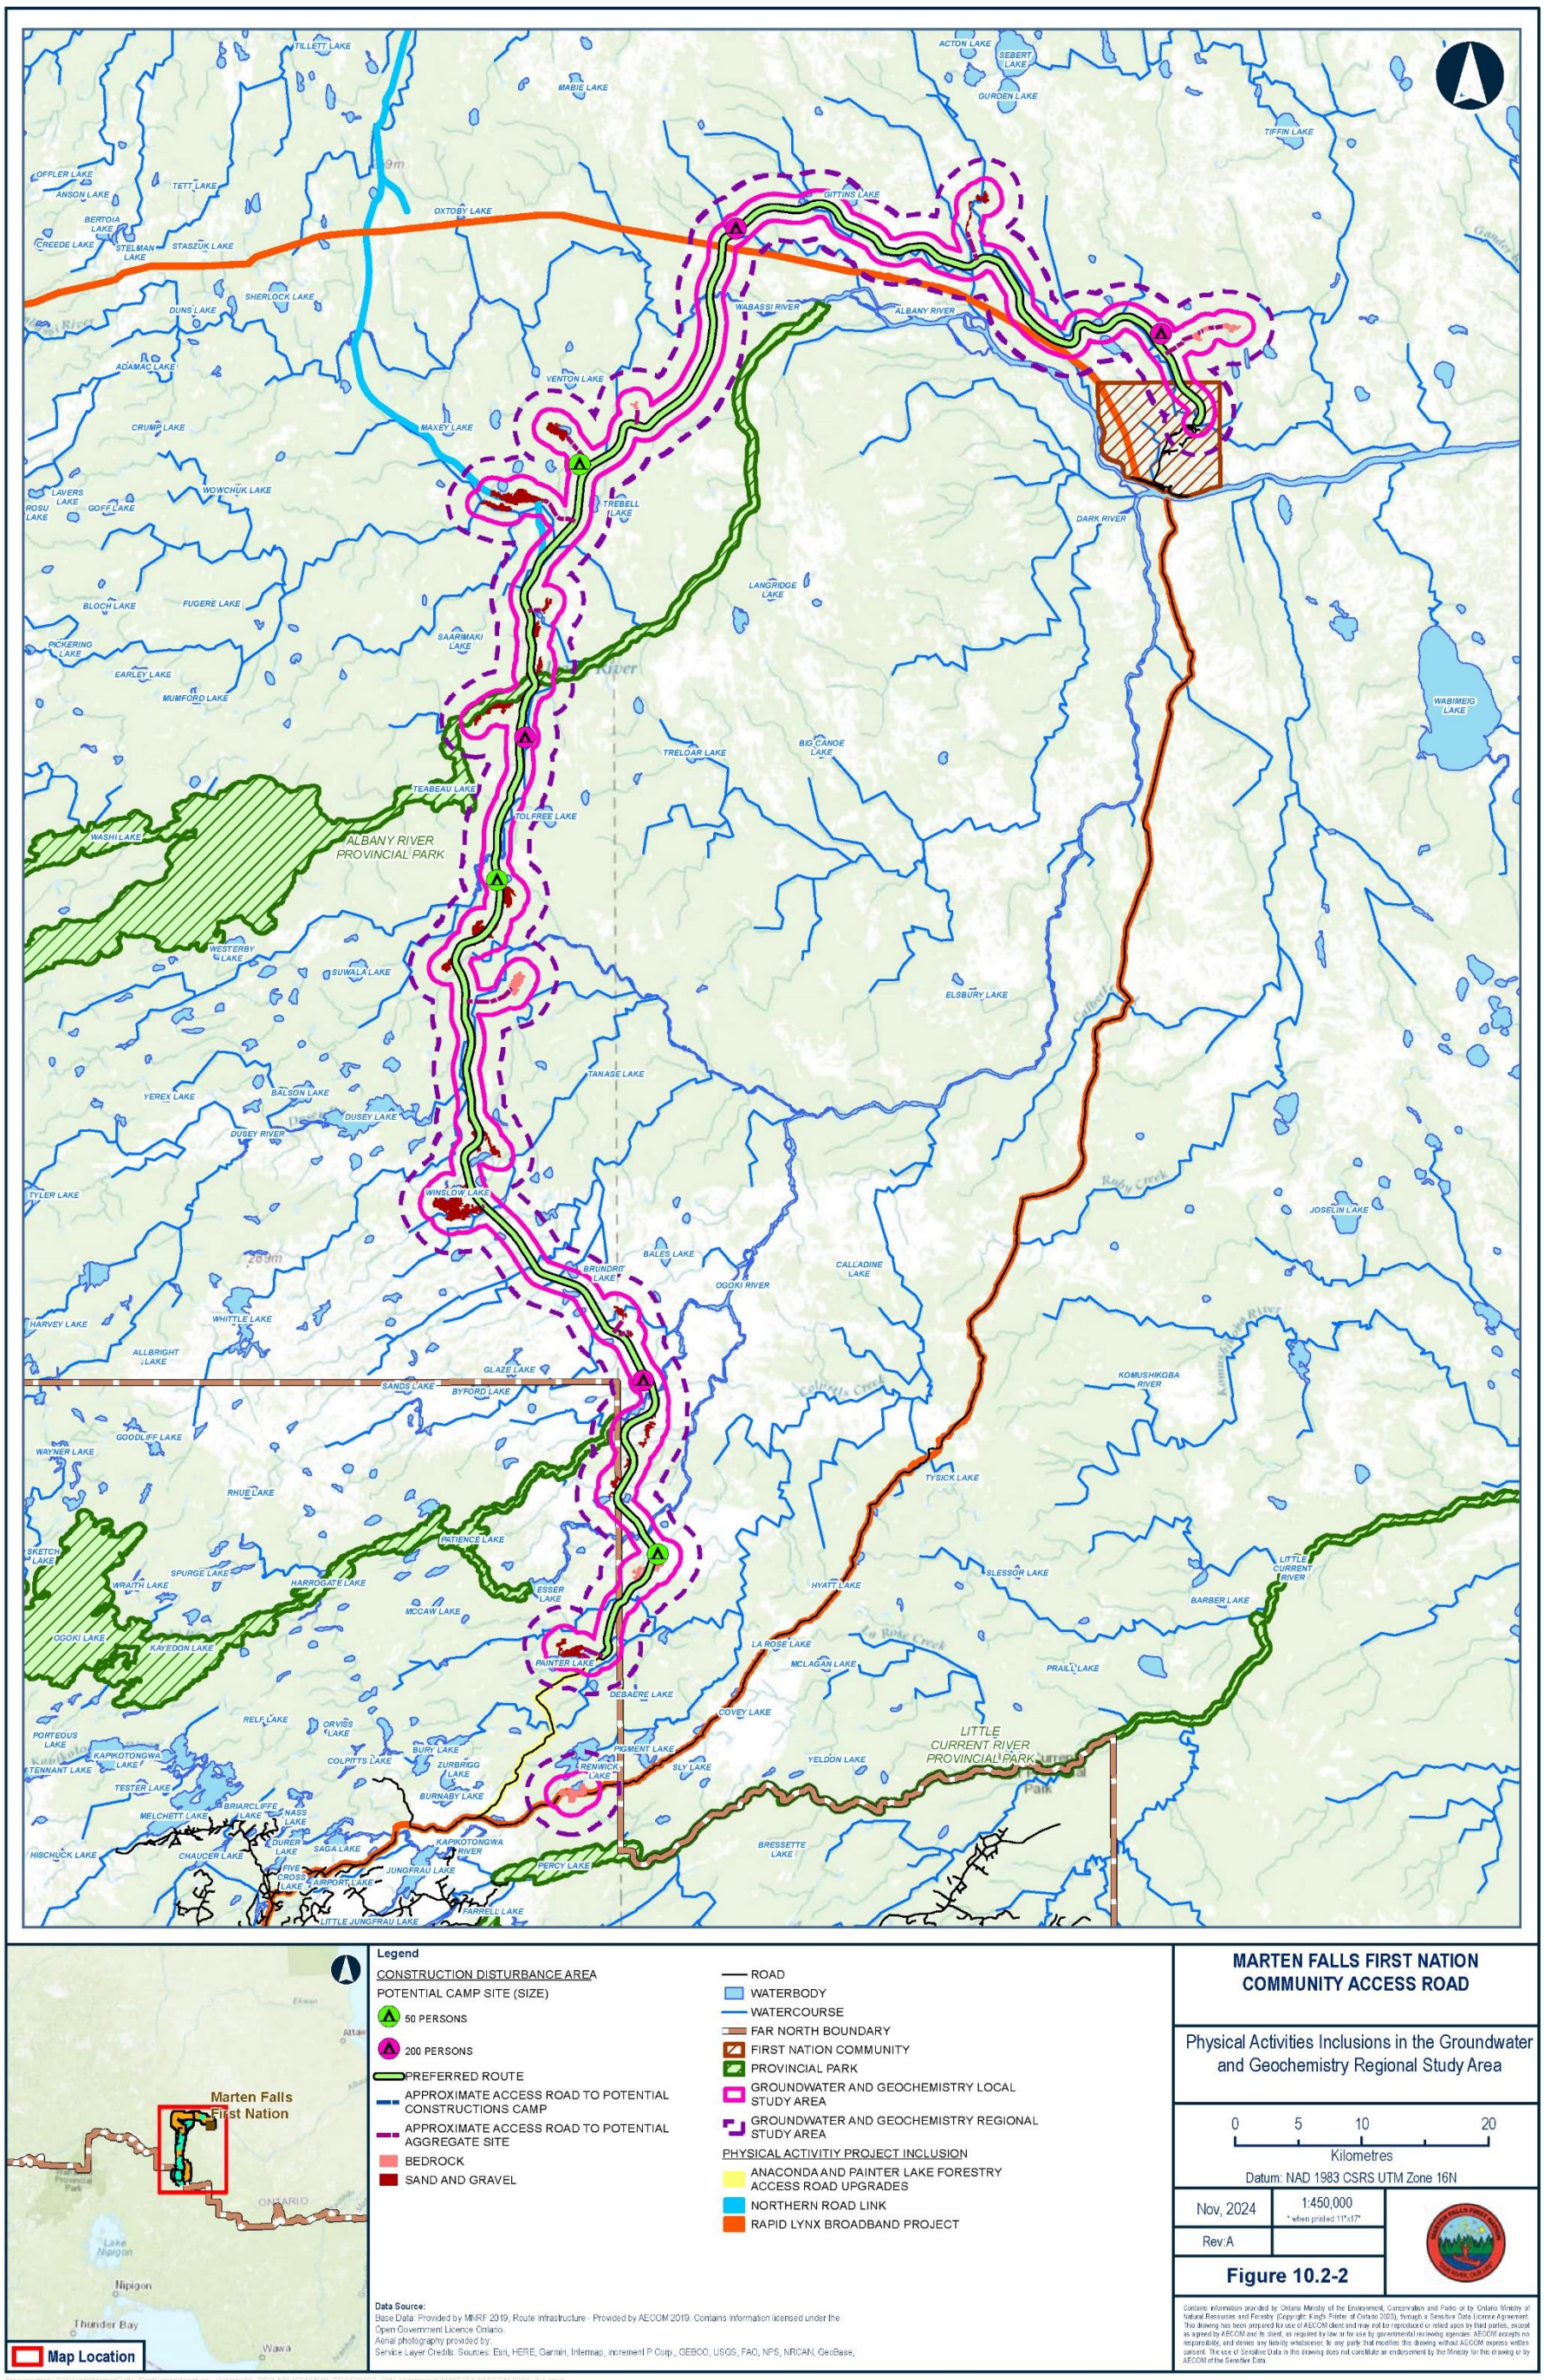
It is anticipated that mitigation and enhancement measures will be, or have been, implemented to limit habitat loss and alteration during the construction of the projects, as well as limit increased access and harvest pressure and associated potential for

introduction or spread of invasive species or pathogens during construction and operations. It is anticipated that these mitigation and enhancement measures will be similar to those implemented for the Community Access Road. Refer to **Section 9.3.3** for a complete description of the proposed mitigation measures for fish and fish habitat.

These projects will also be required to meet permitting requirements from the Ministry of Natural Resources and Fisheries and Oceans Canada.

10.2.3.4 Determination of Significance

Overall, the valued component fish populations are expected to remain to be self-sustaining and ecologically effective; therefore, the predicted cumulative effects on fish and fish habitat are assessed as **not significant**. Based on the Cumulative Effects Assessment, the characterization of cumulative effects was considered to be the same as the residual effects characterization for both interactions carried forward. The magnitude of the predicted cumulative effects remained low for changes to fish habitat quantity and quality through physical alteration from work below the high-water mark and medium for changes to fish survival and reproduction from improved public access to recreational angling areas.



10.2.4 Groundwater and Geochemistry

Five valued components with residual effects were carried forward to the groundwater and geochemistry Cumulative Effects Assessment:

- Changes to groundwater quantity due to pit or quarry dewatering;
- Changes to groundwater quantity valued component due to road construction in peatland areas;
- Changes to groundwater quality valued component due to construction wastes and wastewater discharges;
- Changes to groundwater quality valued component due to blasting residues; and
- Changes to groundwater quality valued component due to road maintenance.

The locations of the projects considered for the Cumulative Effects Assessment in relation to the groundwater Regional Study Area are shown on **Figure 10.2-2**.

Figure 10.2-2: Physical Activities Inclusions in the Groundwater and Geochemistry Regional Study Area

10.2.4.1 Changes to Groundwater Quantity due to Pit or Quarry Dewatering

It is expected that the sizes and numbers of aggregate pits and quarries used for the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades would be similar to or slightly less than those required for the Community Access Road and that, there would not be any additional aggregate pits or quarries required where the projects overlap. This means that there would not be any additional cumulative changes to groundwater quantity due to pit or quarry dewatering in the areas of spatial or temporal overlap.

There is no aggregate pit or quarry dewatering expected as part of the Rapid Lynx Broadband project and therefore no changes to groundwater quantity due to pit or quarry dewatering cumulative effects are assessed for this project.

10.2.4.2 Changes to Groundwater Quantity Due to Road Construction in Peatland Areas

The road projects would not be expected to cross the same peatland area in more than one location with the possible exception of the junction between the Community Access Road and the Northern Road Link. Therefore, it is not expected that there would be any additional cumulative changes to groundwater quantity due to road construction in peatland areas in the areas of spatial or temporal overlap.

There is no road construction expected as part of the Rapid Lynx Broadband project, and installation for the project is not expected to overlap temporally with Community Access Road construction; therefore, no cumulative effects are expected.

10.2.4.3 Changes to Groundwater Quality Due to Construction Waste and Wastewater Discharges

It is expected that the potential amounts of waste and wastewater discharges for the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades would be similar to or slightly less than those required for the Community Access Road and that, there would not be any additional waste or wastewater discharges where the projects overlap. Therefore, there are no additional expected cumulative changes to groundwater quality due to construction waste and wastewater discharges in the areas of spatial or temporal overlap.

There is no construction waste or wastewater discharges expected as part of the Rapid Lynx Broadband project and therefore no changes to groundwater quality due to construction waste and wastewater discharges cumulative effects are assessed for this project.

10.2.4.4 Changes to Groundwater Quality Due to Blasting Residues

It is expected that the potential amounts of blasting and generation of blasting residues for the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades would be similar to or less than those required for the Community Access Road and that there would only be a limited potential for additional blasting residue effects in the area where the Northern Road Link and the Community Access Road overlap spatially. Therefore, there may be additional cumulative effects on groundwater quality due to blasting residues in the area of spatial and temporal overlap between the Community Access Road and the Northern Road Link if both are constructed at the same time.

Other spatial and temporal overlaps between the Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades would not be expected to result in any additional cumulative effects greater than the residual effects of the respective projects.

There is no blasting and therefore no blasting residues expected as part of the Rapid Lynx Broadband project based on available information and therefore no changes to groundwater quality due to blasting residues cumulative effects are assessed for this project.

10.2.4.5 Changes to Groundwater Quality Due to Road Maintenance

It is possible that there would be potential for additional road maintenance effects in the area where the Northern Road Link and the Community Access Road would meet, and an increased concentration of road maintenance chemicals used at that intersection point. Therefore, there would be potential for additional cumulative effects on groundwater quality due to road maintenance activities in that area.

Other spatial overlaps between the Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades would not be expected to result in any additional cumulative effects greater than the residual effects of the respective projects.

There is no road maintenance or similar activities expected as part of the Rapid Lynx Broadband project based on available information and therefore no changes to groundwater quality due to road maintenance cumulative effects are assessed for this project.

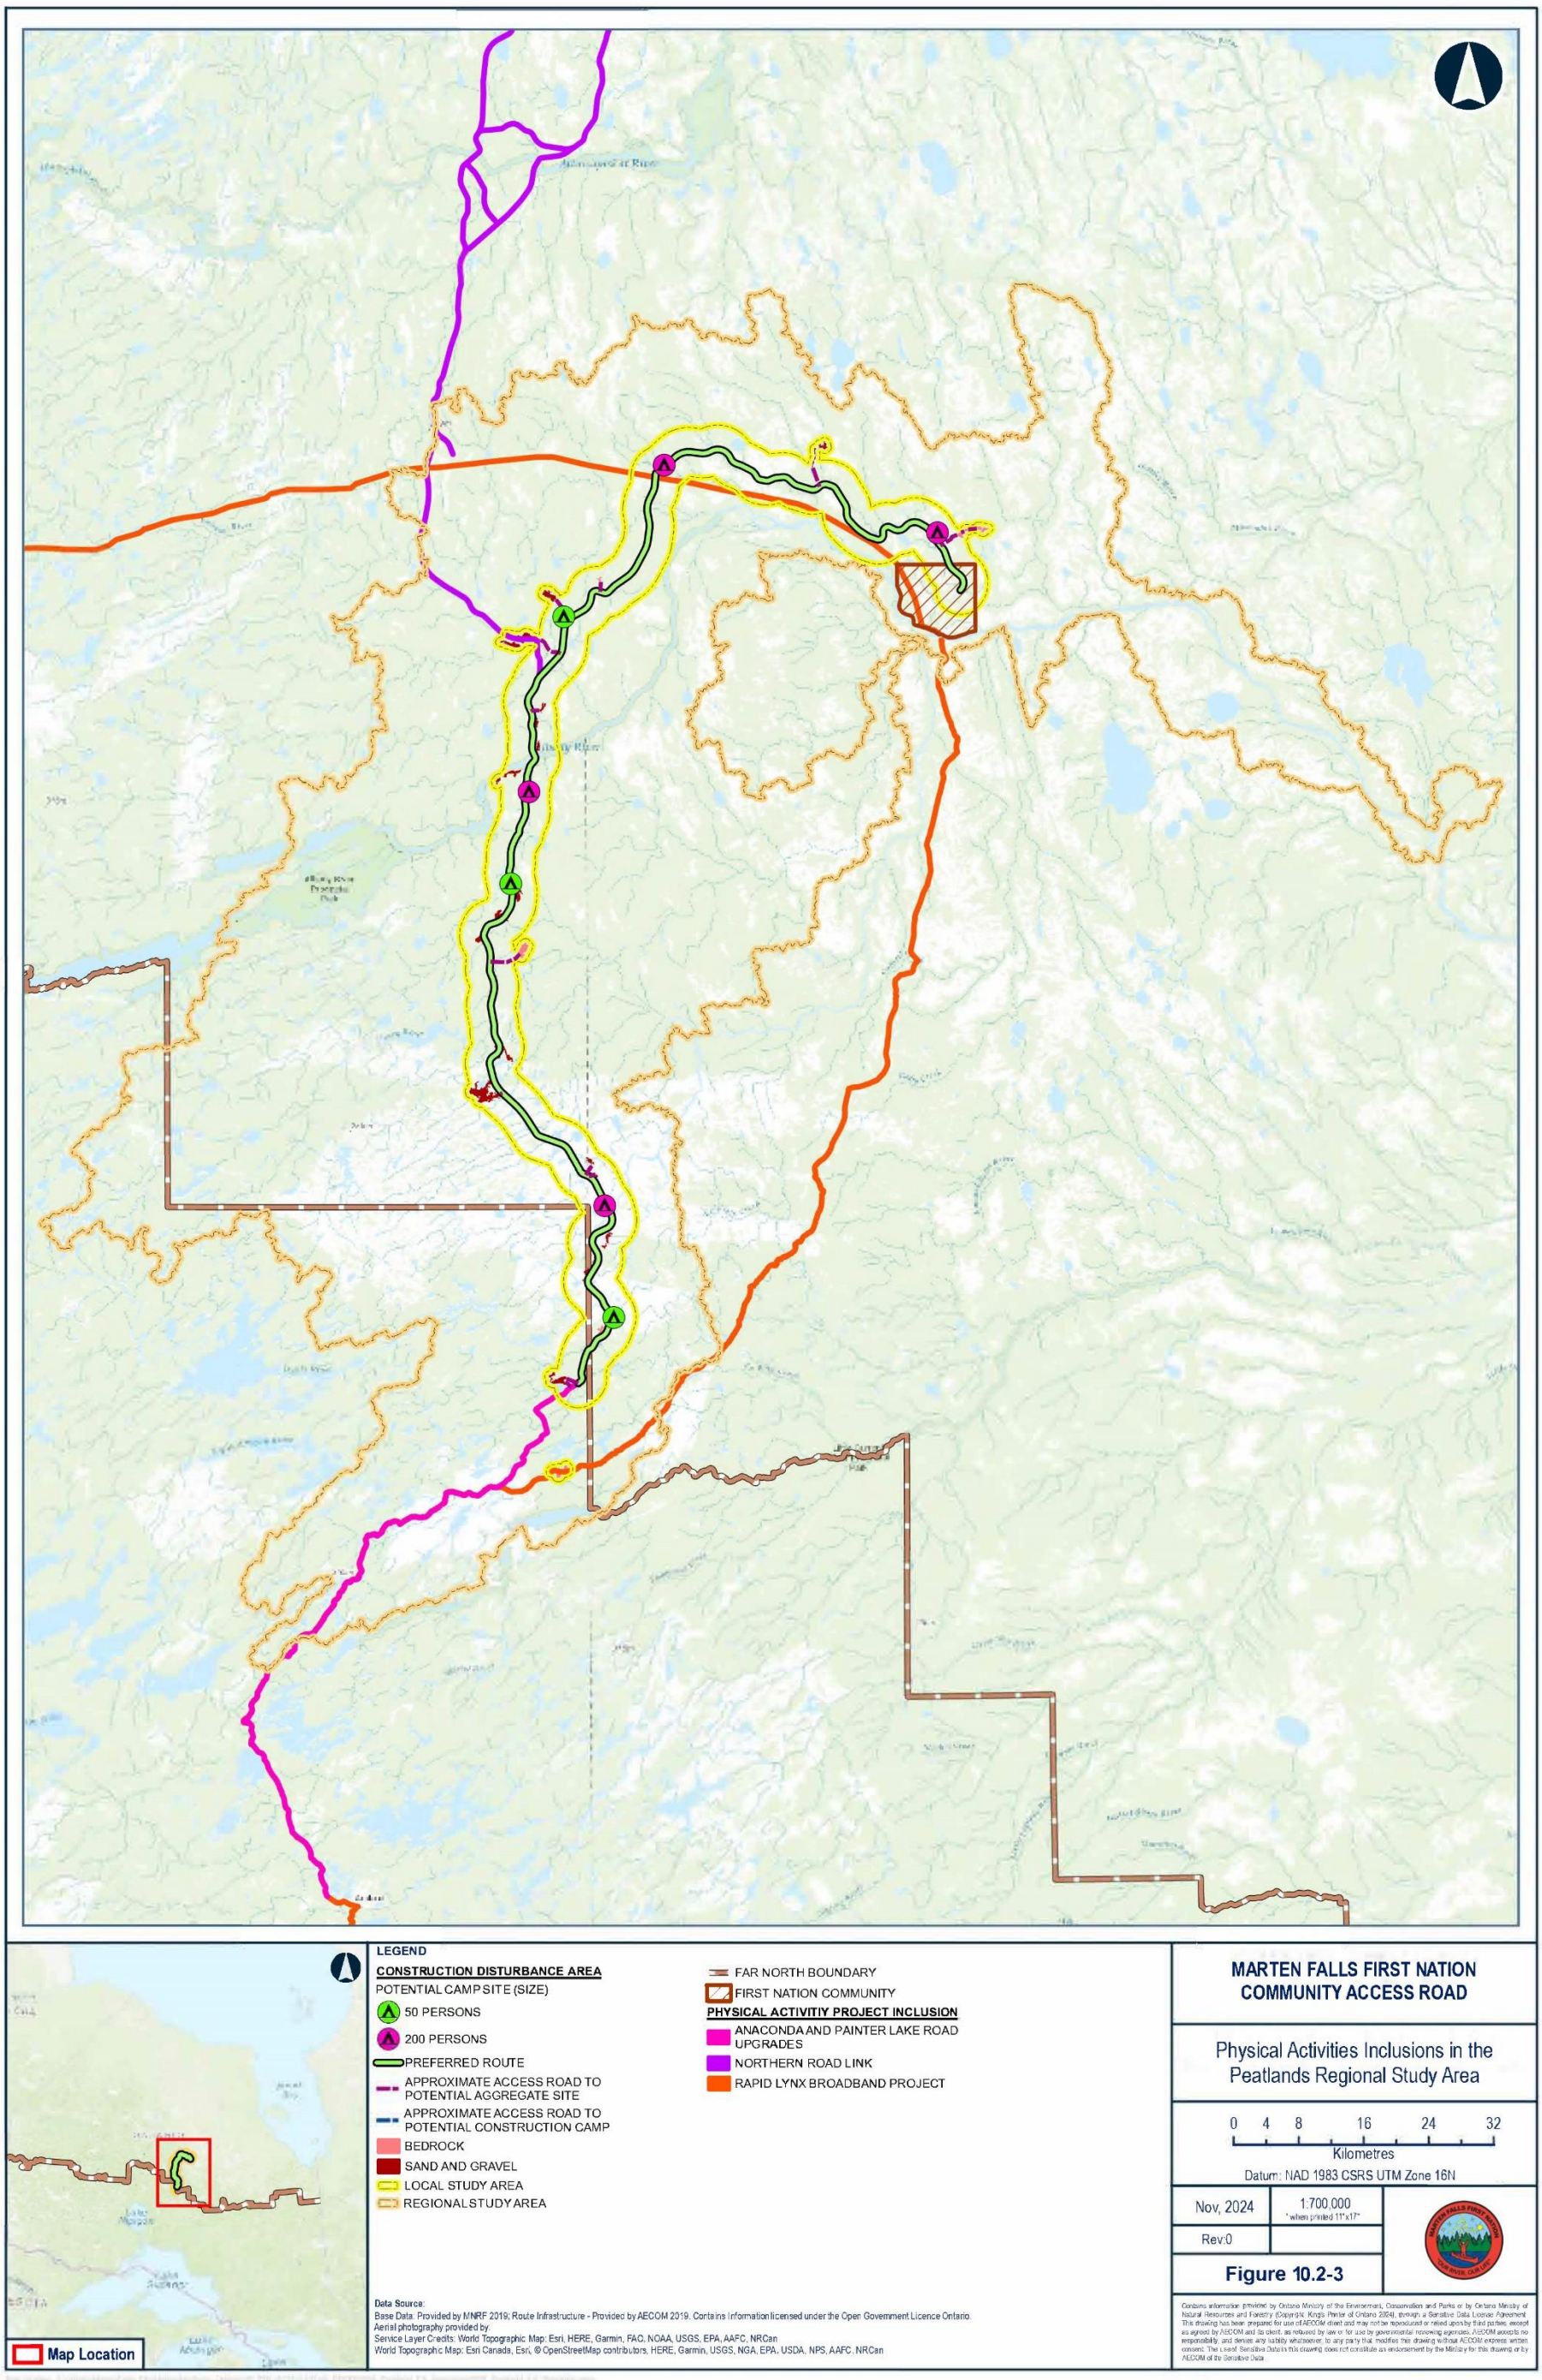
10.2.4.6 Mitigation Measures

No additional mitigation measures are proposed for changes to groundwater and geochemistry. Based on the assessment above, the predicted cumulative effects are not greater than the predicted residual effects for the Community Access Road. It is assumed that the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades will have mitigation plans comparable to the Community Access Road in place during their construction and operation. Refer to **Section 9.3.4** for a complete description of the proposed mitigation measures for groundwater and geochemistry.

As a best practice, it is suggested that the monitoring programs of the Community Access Road and any past, existing, and future physical activities / projects share relevant monitoring data for areas where predicted effects may overlap.

10.2.4.7 Determination of Significance

Significance was determined only for disciplines where it was required to meet federal or provincial requirements. For the purposes of this Cumulative Effects Assessment, significance of the effects for groundwater and geochemistry was not determined.



10.2.5 Peatlands

Four valued components with residual effects were carried forward to the peatlands Cumulative Effects Assessment:

- Direct peatland loss;
- Changes to groundwater;
- Fragmentation and edge effects; and
- Fugitive dust emissions.

The locations of the projects considered for the Cumulative Effects Assessment in relation to the peatlands Regional Study Area are shown on **Figure 10.2-3**.

Figure 10.2-3: Physical Activities Inclusions in the Peatlands Regional Study Area

10.2.5.1 Direct Peatland Loss

Past, present, and reasonably foreseeable activities including a 100-metre buffer are predicted to remove a combined 4,532.5 hectares of peatland. This is expected to increase the percentage of peatland loss in the peatlands effects assessment Regional Study Area from 0.3 percent (for the Community Access Road only) to 0.7 percent, as shown on **Table 10.2-3**.

Table 10.2-3: Peatland Loss in the Peatlands Effects Assessment Regional Study Area

Peatland Type	Peatlands Effects Assessment Regional Study Area (Footnote a)		
	Existing Conditions Area (hectares)	Area of Peatland Loss (hectares)	Percent Change (percent)
Bog	157,240.2	338.7	0.2%
Fen	219,950.5	1,886.9	0.9%
Organic Swamp	242,363	2,261.2	0.9%
Organic Marsh	3,875.3	45.7	1.2%
Total	**623,429**	**4,532.5**	**0.7%**

Footnotes: (a) Wetland area values within the Regional Study Area represent a combination of area values from delineated peatland communities completed for the Community Access Road within the existing conditions Local Study Area, and Ontario Land Cover Compilation Version 2.0 mapping for areas beyond the limits of the existing conditions Local Study Area. The Ontario Land Cover Compilation layer is a compilation of Far North Land Cover Version 1.4, Southern Ontario Land Resource Information System Version 1.2, and Provincial Land Cover 2000 Edition. The Ontario Land Cover mapping does not differentiate between organic and mineral wetland communities. Therefore, the wetland area values may be an overestimation.

10.2.5.2 Changes in Groundwater in Peatlands

The Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades may cause alterations to groundwater quality, drainage patterns, recharge rates and increased or decreased groundwater levels due to activities such as road construction through peatlands, changes to topography, short-term water-taking, pit / quarry dewatering, and discharge of water.

No additional pits or quarries are expected to be required where the projects overlap. Therefore, no additional cumulative changes to groundwater quantity due to pit or quarry dewatering in peatland areas of spatial or temporal overlap between the reasonably foreseeable activities.

The projects are not expected to cross the same groundwater catchment area in more than one location, with the possible exception of the junction between the Community

Access Road and the Northern Road Link. Therefore, no additional cumulative changes to groundwater quantity are expected due to road construction in peatland areas.

The Rapid Lynx Broadband project is anticipated to be buried approximately 1 metre underground and underneath waterbodies, only temporary and minimal changes in groundwater are expected during construction. Any peatlands effects from changes in groundwater would be expected to be local and short-term and would not be expected to overlap temporally with construction.

It should be noted that changes to groundwater can cause changes to soils and vegetation health / composition thereby changing the composition and function of retained peatland communities. If changes to groundwater regimes are sufficient to change the composition of a peatland community, then the availability, distribution, composition, and function of that altered peatland community type will also eventually be affected within the effects assessment Regional Study Area. These indirect effects are difficult to quantify as they largely depend on the effectiveness of the mitigation measures that are implemented.

10.2.5.3 Fragmentation of Edge Effects

The Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project will create new linear corridors for at least some portion of their alignments and therefore introduce new fragmentation and edge effects on the landscape.

This will result in an additional 3,559.7 hectares of disturbance within the effects assessment Regional Study Area and the Community Access Road effects assessment Construction Disturbance Area footprint, that is, 4,700.2 hectares, and therefore are predicted to be cumulative residual effects on the availability, distribution, composition, and function of peatland ecosystems.

Climate change may have additional negative effects on the availability, distribution, composition and function of peatland ecosystems, although these effects are expected to occur even in the absence of further fragmentation and edge effects.

10.2.5.4 Fugitive Dust Emissions

The Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are predicted to result in fugitive dust emissions. Dust accumulation may locally and directly impact peatland vegetation by smothering plant tissues, hindering gas exchange, and reducing photosynthesis by blocking sunlight (Hirano et al., 1995; Prajapati, 2012).

Measurable changes to the availability, distribution, function, and composition of peatland ecosystems may occur from increased fugitive dust emissions associated with the Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project within the effects assessment Regional Study Area.

10.2.5.5 Mitigation Measures

It is anticipated that the mitigation measures that will be implemented to minimize impacts to peatlands during the construction of the Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project will be similar to those implemented for the Community Access Road. No additional mitigation measures are proposed to further mitigate cumulative effects. Refer to **Section 9.3.5** for a complete description of the proposed mitigation measures for peatlands.

It is expected that the effectiveness of mitigation measures for these activities, including the Community Access Road, will be evaluated throughout construction and operation, and will be modified or enhanced as necessary through adaptive management.

As a best practice, it is suggested that the monitoring programs of the Community Access Road and any reasonably foreseeable developments share relevant monitoring data for areas where predicted effects may overlap.

10.2.5.6 Determination of Significance

Peatland ecosystems are expected to remain abundant, intact, and well distributed across the effects assessment Regional Study Area; however, this is dependent on the success of the proposed mitigations, including the implementation of the “floating road” construction technique for crossing peatland ecosystems. While it is predicted that the contribution of the Community Access Road and other reasonably foreseeable developments to cumulative residual effects on peatland ecosystems in the effects assessment Regional Study Area is not expected to change the self-sustaining and ecologically effective status of peatland ecosystems, there is still a high level of uncertainty surrounding the Community Access Road’s cumulative residual effect on peatland ecosystems resulting from changes to groundwater.

As a result, a precautionary approach has been applied and cumulative residual effects on peatland ecosystems are predicted to be **significant**.

10.2.6 Summary of Cumulative Effects

Table 10.2-4 summarizes the cumulative effects for the water disciplines.

Table 10.2-4: Summary of Predicted Cumulative Effects for Water Disciplines

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
• **Surface Water**	• Surface Water Quantity	• Residual changes to surface water quantity from short-term water taking	• Negative	• Negligible	• Local Study Area	• Short-term	• Frequent	• Reversible	• Probable	• Not Significant	• Moderate
• **Surface Water**	• Surface Water Quantity, Surface Water Quality. Sediment Quality	• Residual changes to surface water quantity, surface water quality, and sediment quality from short-term water discharges	• Negative	• Negligible	• Local Study Areal	• Short-term	• Frequent	• Reversible	• Probable	• Not Significant	• Moderate
• **Surface Water**	• Surface Water Quantity, Surface Water Quality. Sediment Quality	• Residual changes to surface water quantity, surface water quality, and sediment quality during short-term water diversions at waterbody crossings	• Negative	• Negligible	• Construction Disturbance Area	• Short-term	• Infrequent	• Reversible	• Probable	• Not Significant	• Moderate
• **Surface Water**	• Surface Water Quantity, Surface Water Quality. Sediment Quality	• Residual changes to surface water quantity, surface water quality, and sediment quality due to changes in land cover	• Negative	• Negligible	• Construction Disturbance Area	• Long-term	• Frequent	• Irreversible for permanent structures	• Probable	• Not Significant	• Moderate
• **Surface Water**	• Surface Water Quantity, Surface Water Quality. Sediment Quality	• Residual changes to surface water quality and sediment quality from the wash-off of organic debris to nearby waterbodies, and / or increased rates of erosion in disturbed and exposed areas with sediment transport and delivery to adjacent waterbodies	• Negative	• Negligible	• Local Study Area	• Short-term	• Frequent	• Reversible	• Probable	• Not Significant	• Moderate
• **Fish and Fish Habitat**	• Lake Sturgeon, Walleye, Brook Trout, Northern Pike, Lake Whitefish, and Burbot	• Changes to fish habitat quantity and quality through physical alteration of waterbodies where work is below the high-water mark	• Negative	• Low	• Construction Disturbance Area	• Short- to medium-term for temporary waterbody crossings • Long-term for permanent waterbody crossings	• Infrequent	• Reversible for temporary waterbody crossings • Irreversible for permanent waterbody crossings	• Certain (work below the high-water mark)	• Not Significant	• Moderate

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
• **Fish and Fish Habitat**	• Lake Sturgeon, Walleye, Brook Trout, Northern Pike, Lake Whitefish, and Burbot	• Changes to fish survival and reproduction from improved public access to recreational angling areas	• Negative	• Medium	• Regional	• Long-term	• Frequent	• Irreversible	• Possible	• Not Significant	• Moderate
• **Groundwater and Geochemistry**	• Groundwater	• Changes to groundwater quantity due to pit or quarry dewatering	• Negative	• High	• Local	• Medium-term	• Continuous	• Reversible	• Probable	• Not Applicable	• Moderate
• **Groundwater and Geochemistry**	• Groundwater	• Changes to groundwater quantity due to road construction in peatland areas	• Negative	• Medium	• Local	• Long-term	• Continuous	• Irreversible	• Possible	• Not Applicable	• Moderate
• **Groundwater and Geochemistry**	• Groundwater	• Changes to groundwater quality due to construction wastes and wastewater discharges	• Negative	• Medium	• Local	• Medium-term	• Continuous	• Reversible	• Probable	• Not Applicable	• Moderate
• **Groundwater and Geochemistry**	• Groundwater	• Changes to groundwater quality due to blasting residues	• Negative	• Medium	• Local	• Medium-term	• Frequent	• Reversible	• Certain	• Not Applicable	• Moderate
• **Groundwater and Geochemistry**	• Groundwater	• Changes to groundwater quality due to road maintenance	• Negative	• Medium	• Local	• Long-term	• Continuous	• Irreversible	• Certain	• Not Applicable	• Moderate
• **Peatlands**	• Peatland Ecosystems	• Direct peatland loss	• Negative	• Low	• Regional (reasonably foreseeable developments) • Beyond regional (due to climate change)	• Long-term	• Continuous	• Irreversible (for permanent impacts) • Reversible (for temporary impacts where peatlands will be restored)	• Certain (reasonably foreseeable developments) • Probable (climate change)	• Not significant	• Moderate
• **Peatlands**	• Peatland Ecosystems	• Changes to groundwater	• Negative	• Medium	• Regional	• Long-term	• Continuous	• Irreversible	• Probable	• Significant	• High
• **Peatlands**	• Peatland Ecosystems	• Fragmentation and edge effects	• Negative	• Negligible	• Regional	• Medium-term	• Frequent	• Irreversible	• Probable	• Not significant	• Moderate
• **Peatlands**	• Peatland Ecosystems	• Fugitive dust emissions	• Negative	• Negligible	• Regional	• Long-term	• Continuous	• Irreversible	• Certain	• Not significant	• Moderate

10.3 Land

10.3.1 Scoping

Where residual effects identified in **Section 9** were negligible magnitude, unlikely or possible to occur, or positive in direction, the effect was not carried forward into the Cumulative Effects Assessment. The valued components with residual effects that have been carried forward for the Cumulative Effects Assessment for land disciplines are described in **Table 10.3-1**.

To determine the spatial boundaries of potential cumulative effects, the projects listed in **Table 10.3-2** were considered for the Cumulative Effects Assessment. The remaining projects on the Project Inclusions List were determined to have no spatial or temporal overlap with the land disciplines study areas; therefore, they were not considered as part of the Cumulative Effects Assessment.

Table 10.3-1: Valued Components Carried Forward and Corresponding Spatial and Temporal Boundary for Land Disciplines

Discipline	Valued Component	Spatial Boundary	Temporal Boundary
• **Vegetation**	• Upland Ecosystems • Wetland Ecosystems • Riparian Ecosystems • Designated Areas • Traditional Use Plants • Species at Risk and Species of Conservation Concern	• 11 kilometres buffer on either side of the centreline of the Preferred Route	• Construction • Operations
• **Wildlife**	• Wildlife (non-ungulate, non-bird, non-wolverine)	• 11 kilometres buffer on either side of the Construction Disturbance Area	• Construction • Operations
• **Wildlife**	• Wolverine	• All Wildlife Management Units that intersect with the Construction Disturbance Area	• Construction • Operations
• **Wildlife - Birds**	• Birds	• 11 kilometres buffer on either side of the centreline of the Preferred Route (506,756 hectares)	• Construction • Operations
• **Wildlife - Ungulates**	• Boreal Caribou	• Boreal caribou ranges that are intersected by the Ungulate Local Study Area (Missisa Range, Nipigon Range) and adjacent boreal caribou ranges which may be affected by indirect habitat loss (Ozhiski Range, Pagwachuan range) (19,250,753 hectares)	• Construction • Operations
• **Wildlife - Ungulates**	• Moose	• All Wildlife Management Units that are intersected by the Ungulate Local Study Area (17, 1D, 18A) (16,139,060 hectares)	• Construction • Operations
• **Physiography, Soils and Terrain**	• Physiography, Terrain, and Soils	• Regional Study Area - 11 kilometres buffer on either side of the Community Access Road centreline	• Construction • Operations

Table 10.3-2: Project and Physical Activities Carried Forward for Land Disciplines

Discipline(s)	Project	Project Description	Project / Activity Reasonably Foreseeable (Yes / No)	Valued Components Temporal Overlap with Project (Yes / No)	Valued Components Spatial Overlap with Project (Yes / No)
• **Vegetation** • **Wildlife** • **Wildlife - Birds** • **Wildlife - Ungulates** • **Physiography, Soils and Terrain**	• Northern Road Link	• Marten Falls First Nation and Webequie First Nation are proposing to build, operate and maintain an all-season multi-use road and associated infrastructure between the Community Access Road that has been proposed by Marten Falls First Nation and the supply road that has been proposed by Webequie First Nation. • Terms of Reference for the preparation of an Environmental Assessment were approved March 3, 2023.	• Yes	• Yes	• Yes
• **Vegetation** • **Wildlife** • **Wildlife - Birds** • **Wildlife - Ungulates** • **Physiography, Soils and Terrain**	• Anaconda and Painter Lake Forestry Access Road Upgrades	• Upgrades to existing road will be required for heavy vehicles accessing the Community Access Road route during construction and operations. • Currently discussions on proponency and scope of work are underway. • Potential scope of work is expected to include roadway widening, culvert and bridge replacements / rehabilitations to accommodate higher weight vehicles, and road base improvements. • This project will be completed prior to the start of the construction of the Community Access Road; therefore, the upgrade to these roads is not expected to overlap with the construction of the Community Access Road.	• Yes	• Yes	• Yes
• **Vegetation** • **Wildlife** • **Wildlife - Birds** • **Wildlife - Ungulates** • **Physiography, Soils and Terrain**	• Rapid Lynx Broadband	• Approximately 810 kilometres of fibre-optic cables, providing reliable high-speed internet service to five Matawa First Nation communities: Eabametoong, Marten Falls, Neskantaga, Nibinamik, and Webequie with an interconnection at Aroland.	• Yes	• Yes	• Yes

Discipline(s)	Project	Project Description	Project / Activity Reasonably Foreseeable (Yes / No)	Valued Components Temporal Overlap with Project (Yes / No)	Valued Components Spatial Overlap with Project (Yes / No)
• **Vegetation** • **Wildlife** • **Wildlife - Ungulates**	• Ogoki Forest Management Plans	• Forest Management Plans for the Ogoki Forest. • Includes Ogoki-Armstrong Primary Roads as these roads are being used for forest management. • Includes plans for future harvest. • Ogoki Forest is approximately 10,900 square kilometres in size and includes approximately 9,798 square kilometres of forested area. • Majority of the forest is traditional territory and is subject to forest management planning and forest management operations.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Esnagami Road Bypass Upgrade	• Upgrades to existing road to use as a bypass route around Aroland First Nation settlement area by heavy vehicles accessing the Community Access Road route towards the Ring of Fire. • Currently discussions on proponency and scope of work are underway. • Potential scope of work is expected to include roadway widening, bridge and culvert rehabilitation / replacement, and road base improvements.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Transload Facility	• Rail Transload Facility to Aroland First Nation.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Eagle's Nest Project	• Multi-metal underground mine located near McFaulds Lake. • Mine will produce and supply nickel, copper, platinum and palladium. • Deposit contains approximately 11 million tonnes of resources and is estimated to have an initial mine life of 11 years with possibility for a 9-year extension. • Terms of Reference for the project approved June 18, 2015.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Webequie Supply Road	• New all-season road approximately 107 kilometres in length from Webequie First Nation to the mineral deposit near McFaulds Lake for mineral exploration and future mining development activities. • 17 kilometres of the corridor is within Webequie First Nation Reserve Lands.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Ogoki and Long Lac Diversions	• Divert water from a portion of the Hudson Bay watershed into the Lake Superior basin. • Long Lac diversion inflows approximately 39 cubic metres per second into the Great Lakes Basin. • Ogoki diversion inflows approximately 113 cubic metres per second into the Great Lakes Basin.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Victor Diamond Mine	• Fly-in, fly-out open put diamond mine located near James Bay lowlands of northern Ontario. • Mine in operation from 2008 to 2019; however, now closed and in rehabilitation.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Gull Bay Roads Rehabilitation	• Rehabilitate approximately 10 kilometres of roads in the Gull Bay First Nation in Ontario. • Relocation of the community's entrance and exit to Highway 527; rebuilding the road base and widening certain sections; grading and brush clearing to improve sightlines; addressing drainage issues through ditching and the replacement of an estimated 43 culverts; installing street and traffic control signs (for example street, stop, yield and speed signs plus pedestrian warnings); and resurfacing Main Street and Streets A through M with Granular A along with calcium chloride for dust suppression. • Infrastructure Canada issued its Notice of Determination on July 15, 2021, and determined that the project is not likely to cause significant adverse environmental effects.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Wataynikaneyap Transmission Project	• Construction of a 230 kilovolts line between Ignace and Dryden, to Pickle Lake (Phase 1). • Construction of electricity transmission lines to Pickle Lake and north of Red Lake, connecting 17 remote northern Ontario communities to grid power (Phase 2). • Operation of both project phases overlap with the construction and operations of the Community Access Road.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Kasabonika Lake First Nation Band Representative Facility	• The Kasabonika Lake First Nation Band Representative Facility project involves the construction of a new single-story Child and Family Service building and housing facilities for staff in the community of Kasabonika Lake. • Includes tree clearing, lot development, parking lot and laneway construction, connection to community's water and wastewater infrastructure and building construction.	• Yes	• Yes	• Yes

Discipline(s)	Project	Project Description	Project / Activity Reasonably Foreseeable (Yes / No)	Valued Components Temporal Overlap with Project (Yes / No)	Valued Components Spatial Overlap with Project (Yes / No)
• **Wildlife** • **Wildlife - Ungulates**	• Kashechewan First Nation - 20 Lot Development	• Development of 20 lots with future use to build family homes for the community. • Each lot is roughly 929 metres in size. • The project will include site preparation activities including clearing, grubbing, granular placement, and servicing of lots with municipal utilities and services. • The Notice of Determination was issued on November 17, 2023, and determined that the project is not likely to cause significant adverse environmental effects.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Attawapiskat First Nation - Airport Heights Residential Subdivision	• Lot servicing project, for a maximum of 28 serviced residential lots in the proposed Airport Heights Residential Subdivision.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Neskantaga First Nation Community Recreation Centre	• Renovation of the existing community recreation centre and arena, to include an additional 2,400 square feet in size and will include washrooms.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Rehabilitation of Nibinamik Lagoon Sewage Treatment Lagoon and Collection Systems	• Repair and replacement of components of a sewage lagoon and the purchase of a septic truck in Nibinamik First Nation. • Includes re-excavating and repairing 30 manholes and covers, flushing outflow lines, removing and replacing 2 pressure relief values, repairing damaged section of the lagoon and buying a septic truck.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Mushkegowuk James Bay All-Season Road Coastal and Inland	• New all-season access road connecting 4 western James Bay communities and the Provincial highway network. • Includes 525 kilometres of gravel-surface public highway, 70 bridges and 100 additional medium and large diameter culverts to span watercourses.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Accelerated High-Speed Internet Program	• Providing access to reliable, high-speed internet to unserved and underserved communities across the province by the end of 2025.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Birds** • **Wildlife - Ungulates** • **Physiography, Soils and Terrain**	• Winter Access Road Realignment Project	• Funding to remote northern communities for projects involving installation of water crossing infrastructure, such as pre-engineered bridges and culverts, and repairs to existing structures. • Funding for approximately 3,200 kilometres of winter access roads in Northern Ontario.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Seymour Lake Lithium Project	• Lithium deposit near Seymour Lake. • First production targeted in 2026.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Juno Corporation Mining Exploration Activities	• Exploration of minerals in the Ring of Fire. • Mineral exploration permit issued in August 2025.	• Yes	• Yes	• Yes
• **Wildlife** • **Wildlife - Ungulates**	• Gull Bay Roads Rehabilitation	• Rehabilitate approximately 10 kilometres of roads in the Gull Bay First Nation in Ontario. • Relocation of the community's entrance and exit to Highway 527; rebuilding the road base and widening certain sections; grading and brush clearing to improve sightlines; addressing drainage issues through ditching and the replacement of an estimated 43 culverts; installing street and traffic control signs (street, stop, yield and speed signs plus pedestrian warnings); and resurfacing Main Street and Streets A through M with Granular A along with calcium chloride for dust suppression. • Infrastructure Ontario issued its Notice of Determination on July 15, 2021, and determined that the project is not likely to cause significant adverse environmental effects.	• Yes	• Yes	• Yes

10.3.2 Vegetation

Four valued components with residual effects were carried forward to the vegetation Cumulative Effects Assessment:

- Direct vegetation loss;
- Changes to groundwater;
- Fragmentation and edge effects; and
- Fugitive dust emissions.

Cumulative effects on vegetation are shown on **Figure 10.3-1** to **Figure 10.3-3**.

10.3.2.1 Direct Vegetation Loss

The Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are predicted to change the following vegetation availability in the effects assessment Regional Study Area due to direct vegetation loss:

- Removal of a combined 3,140 hectares of Upland Ecosystems, which equates to 3 percent of the Upland Ecosystems within the effects assessment Regional Study Area;
- Removal of 3,921.6 hectares of Wetland Ecosystems, which equates to 1 percent of the Wetland Ecosystems within the effects assessment Regional Study Area;
- Removal of 163.6 hectares of Riparian Ecosystems, which equates to 1 percent of the Riparian Ecosystems within the effects assessment Regional Study Area;
- Remove 5.7 hectares of the Albany River Provincial Park, which equates to less than 1 percent of the total Provincial Park area, and less than 1 percent of the Provincial Park that occurs within the effects assessment Regional Study Area;
- Remove 750.9 hectares of Critical Landform / Vegetation associations, which equates to 1 percent of the Critical Landform / Vegetation associations within the effects assessment Regional Study Area;
- Remove 1,820.2 hectares of suitable habitat for Black Ash, which equates to 5 percent of the suitable habitat available within the effects assessment Local Study Area; and
- Remove 3,520.9 hectares of suitable habitat for Northern Marsh Violet, which equates to 4 percent of the suitable habitat available within the effects assessment Local Study Area.

Figure 10.3-1: Wetland, Upland and Riparian Ecosystems Cumulative Effects

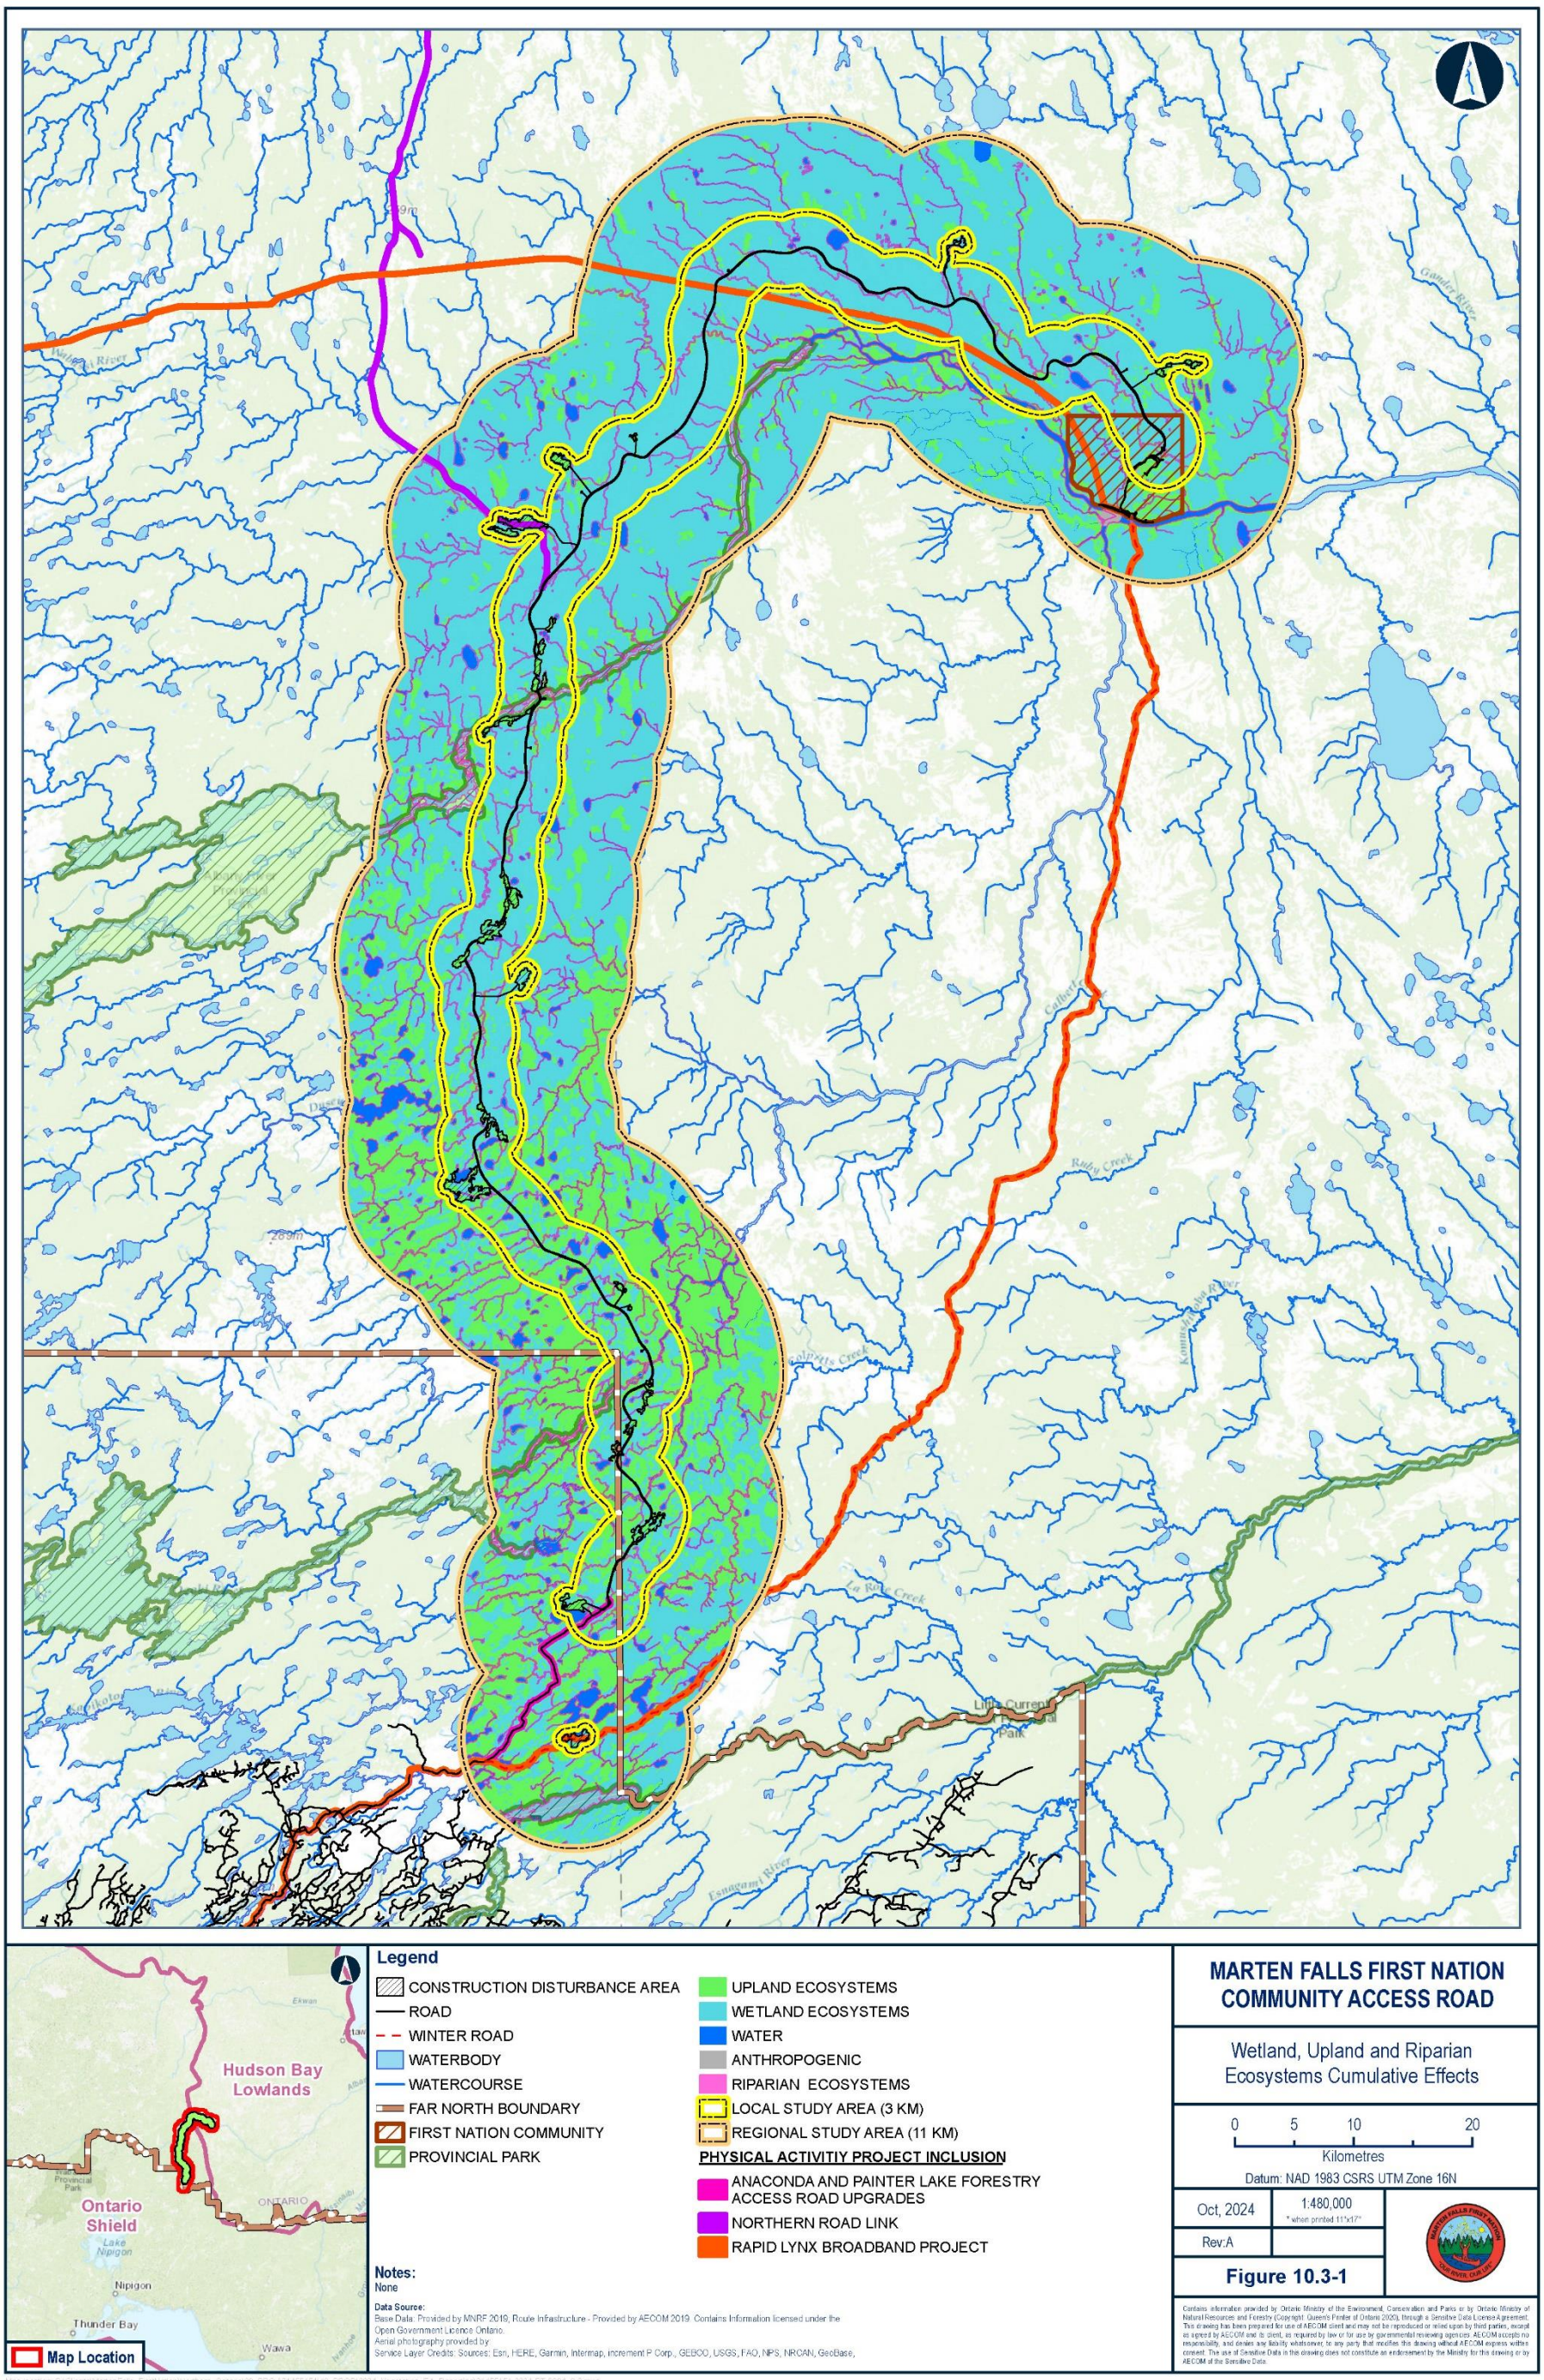


Figure 10.3-2: Traditional Use Plant Habitat Suitability and Accessibility Cumulative Effects

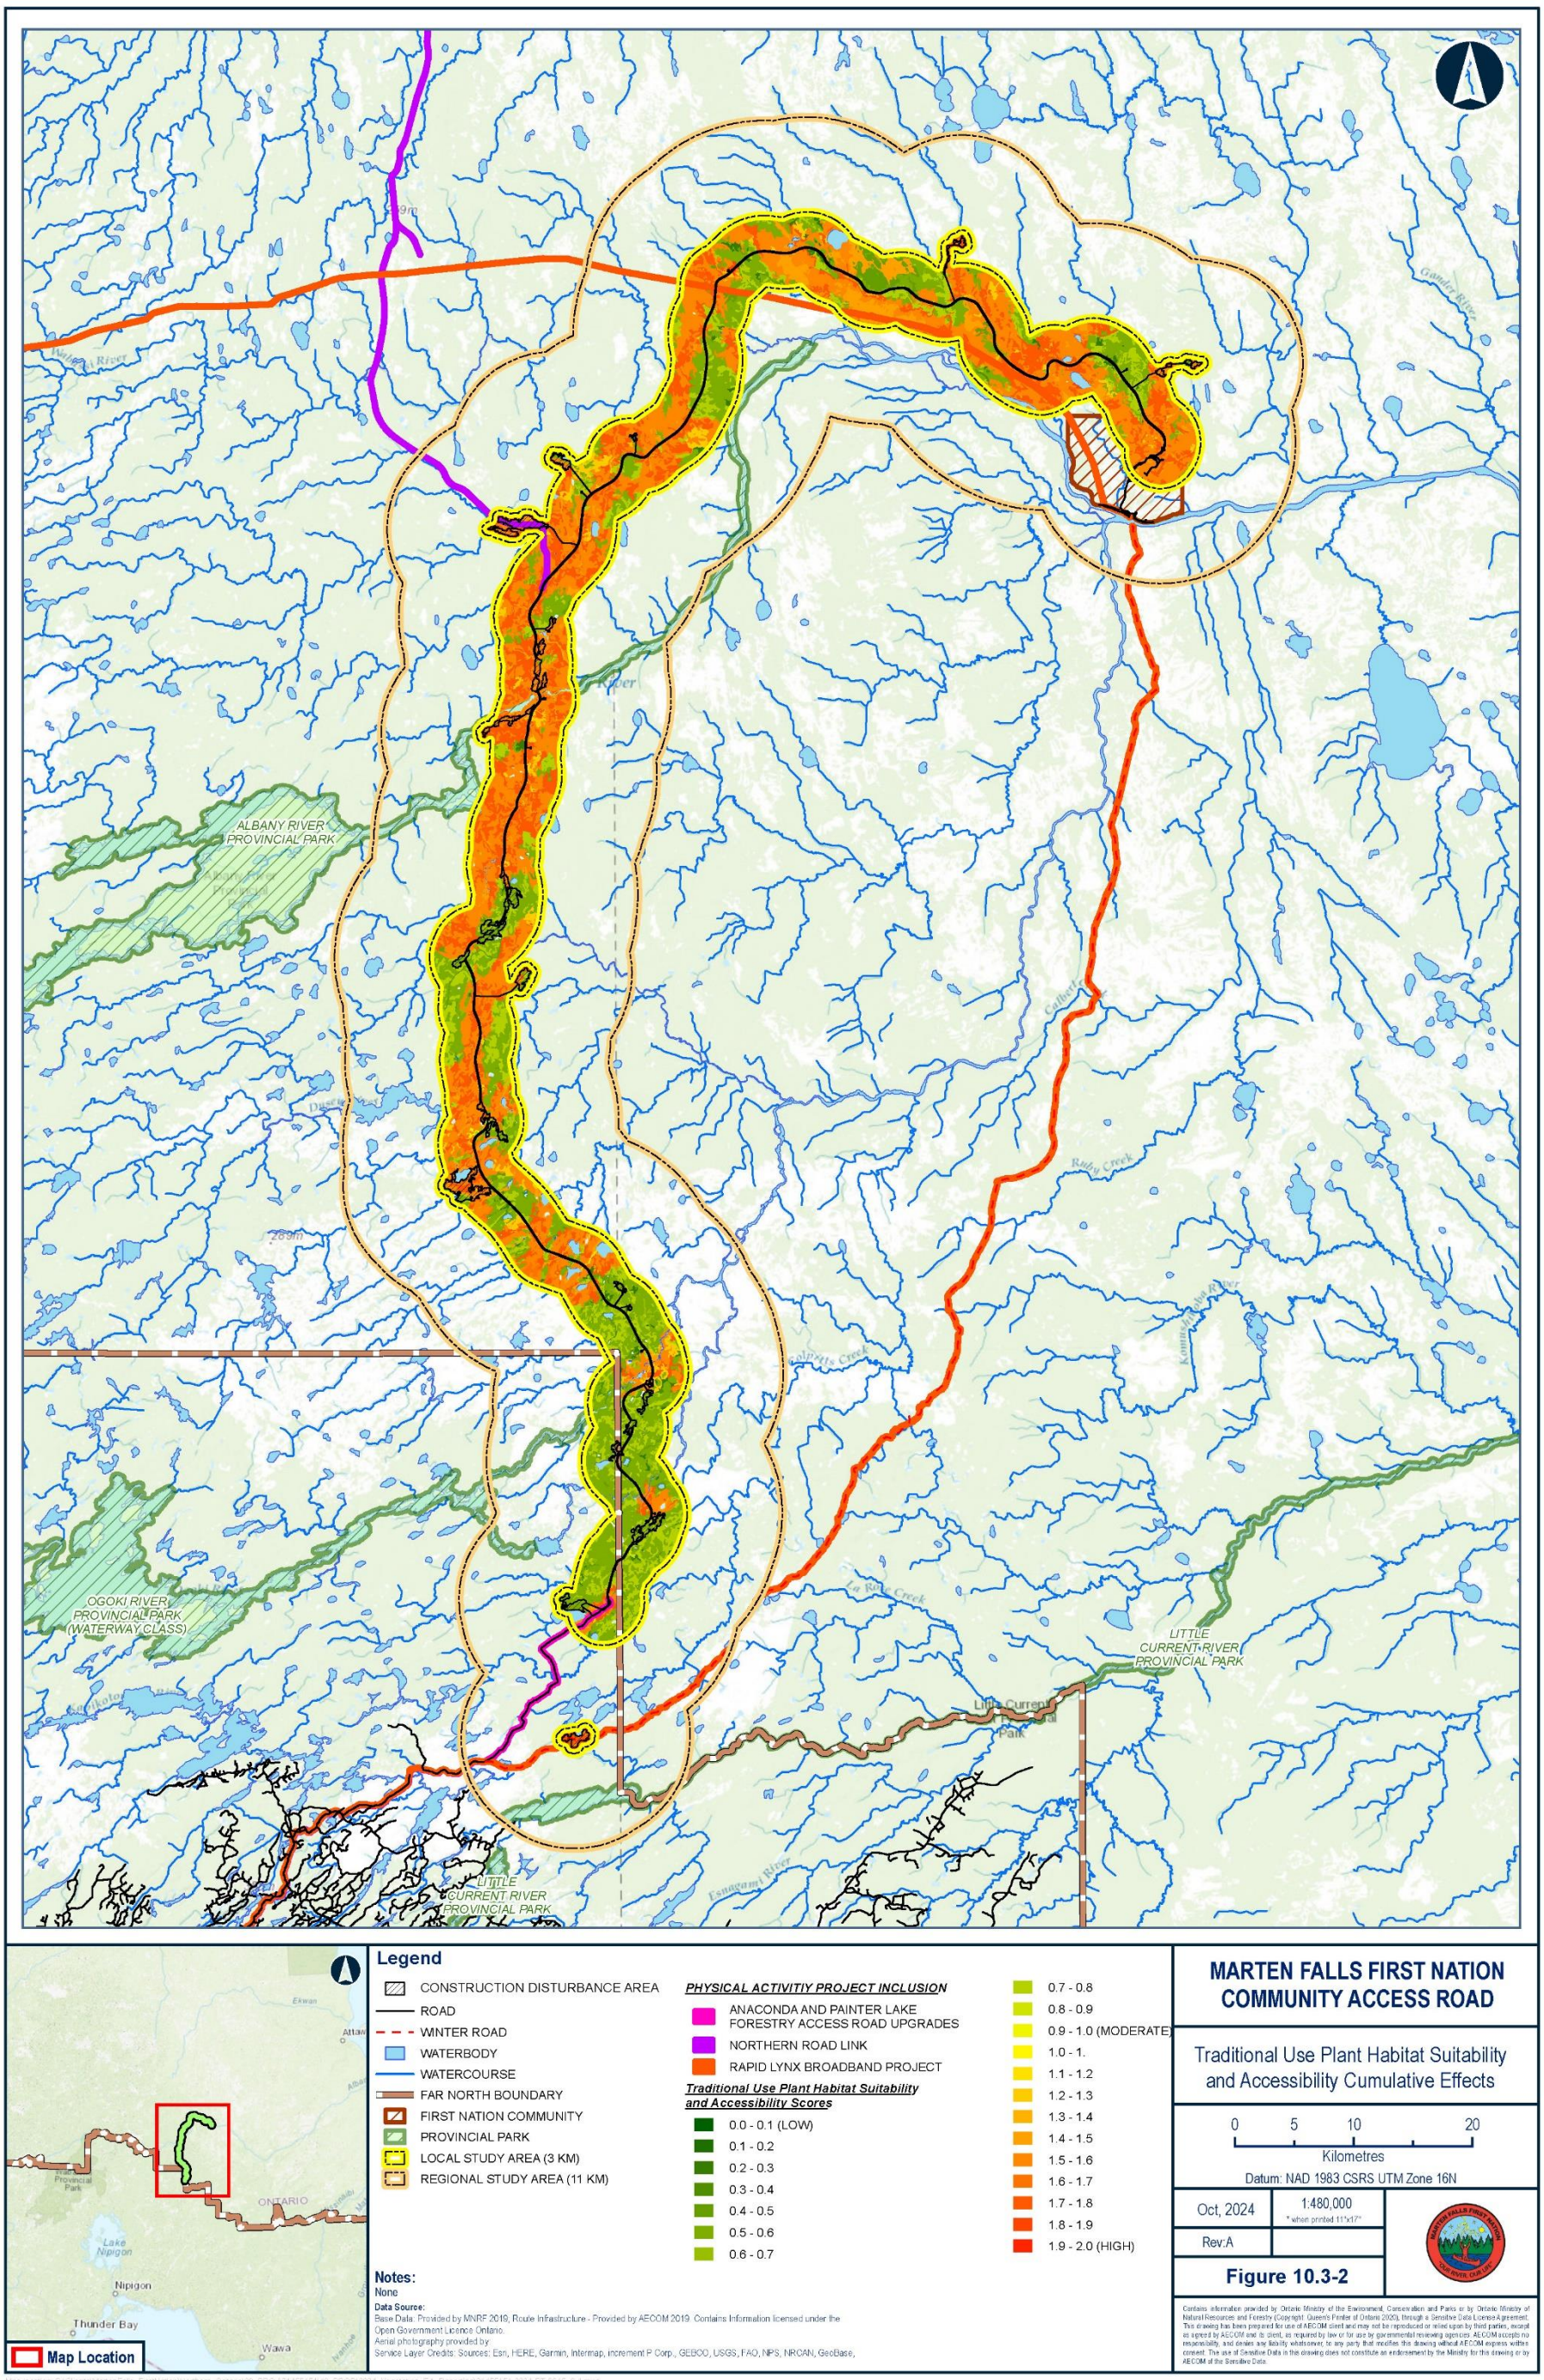

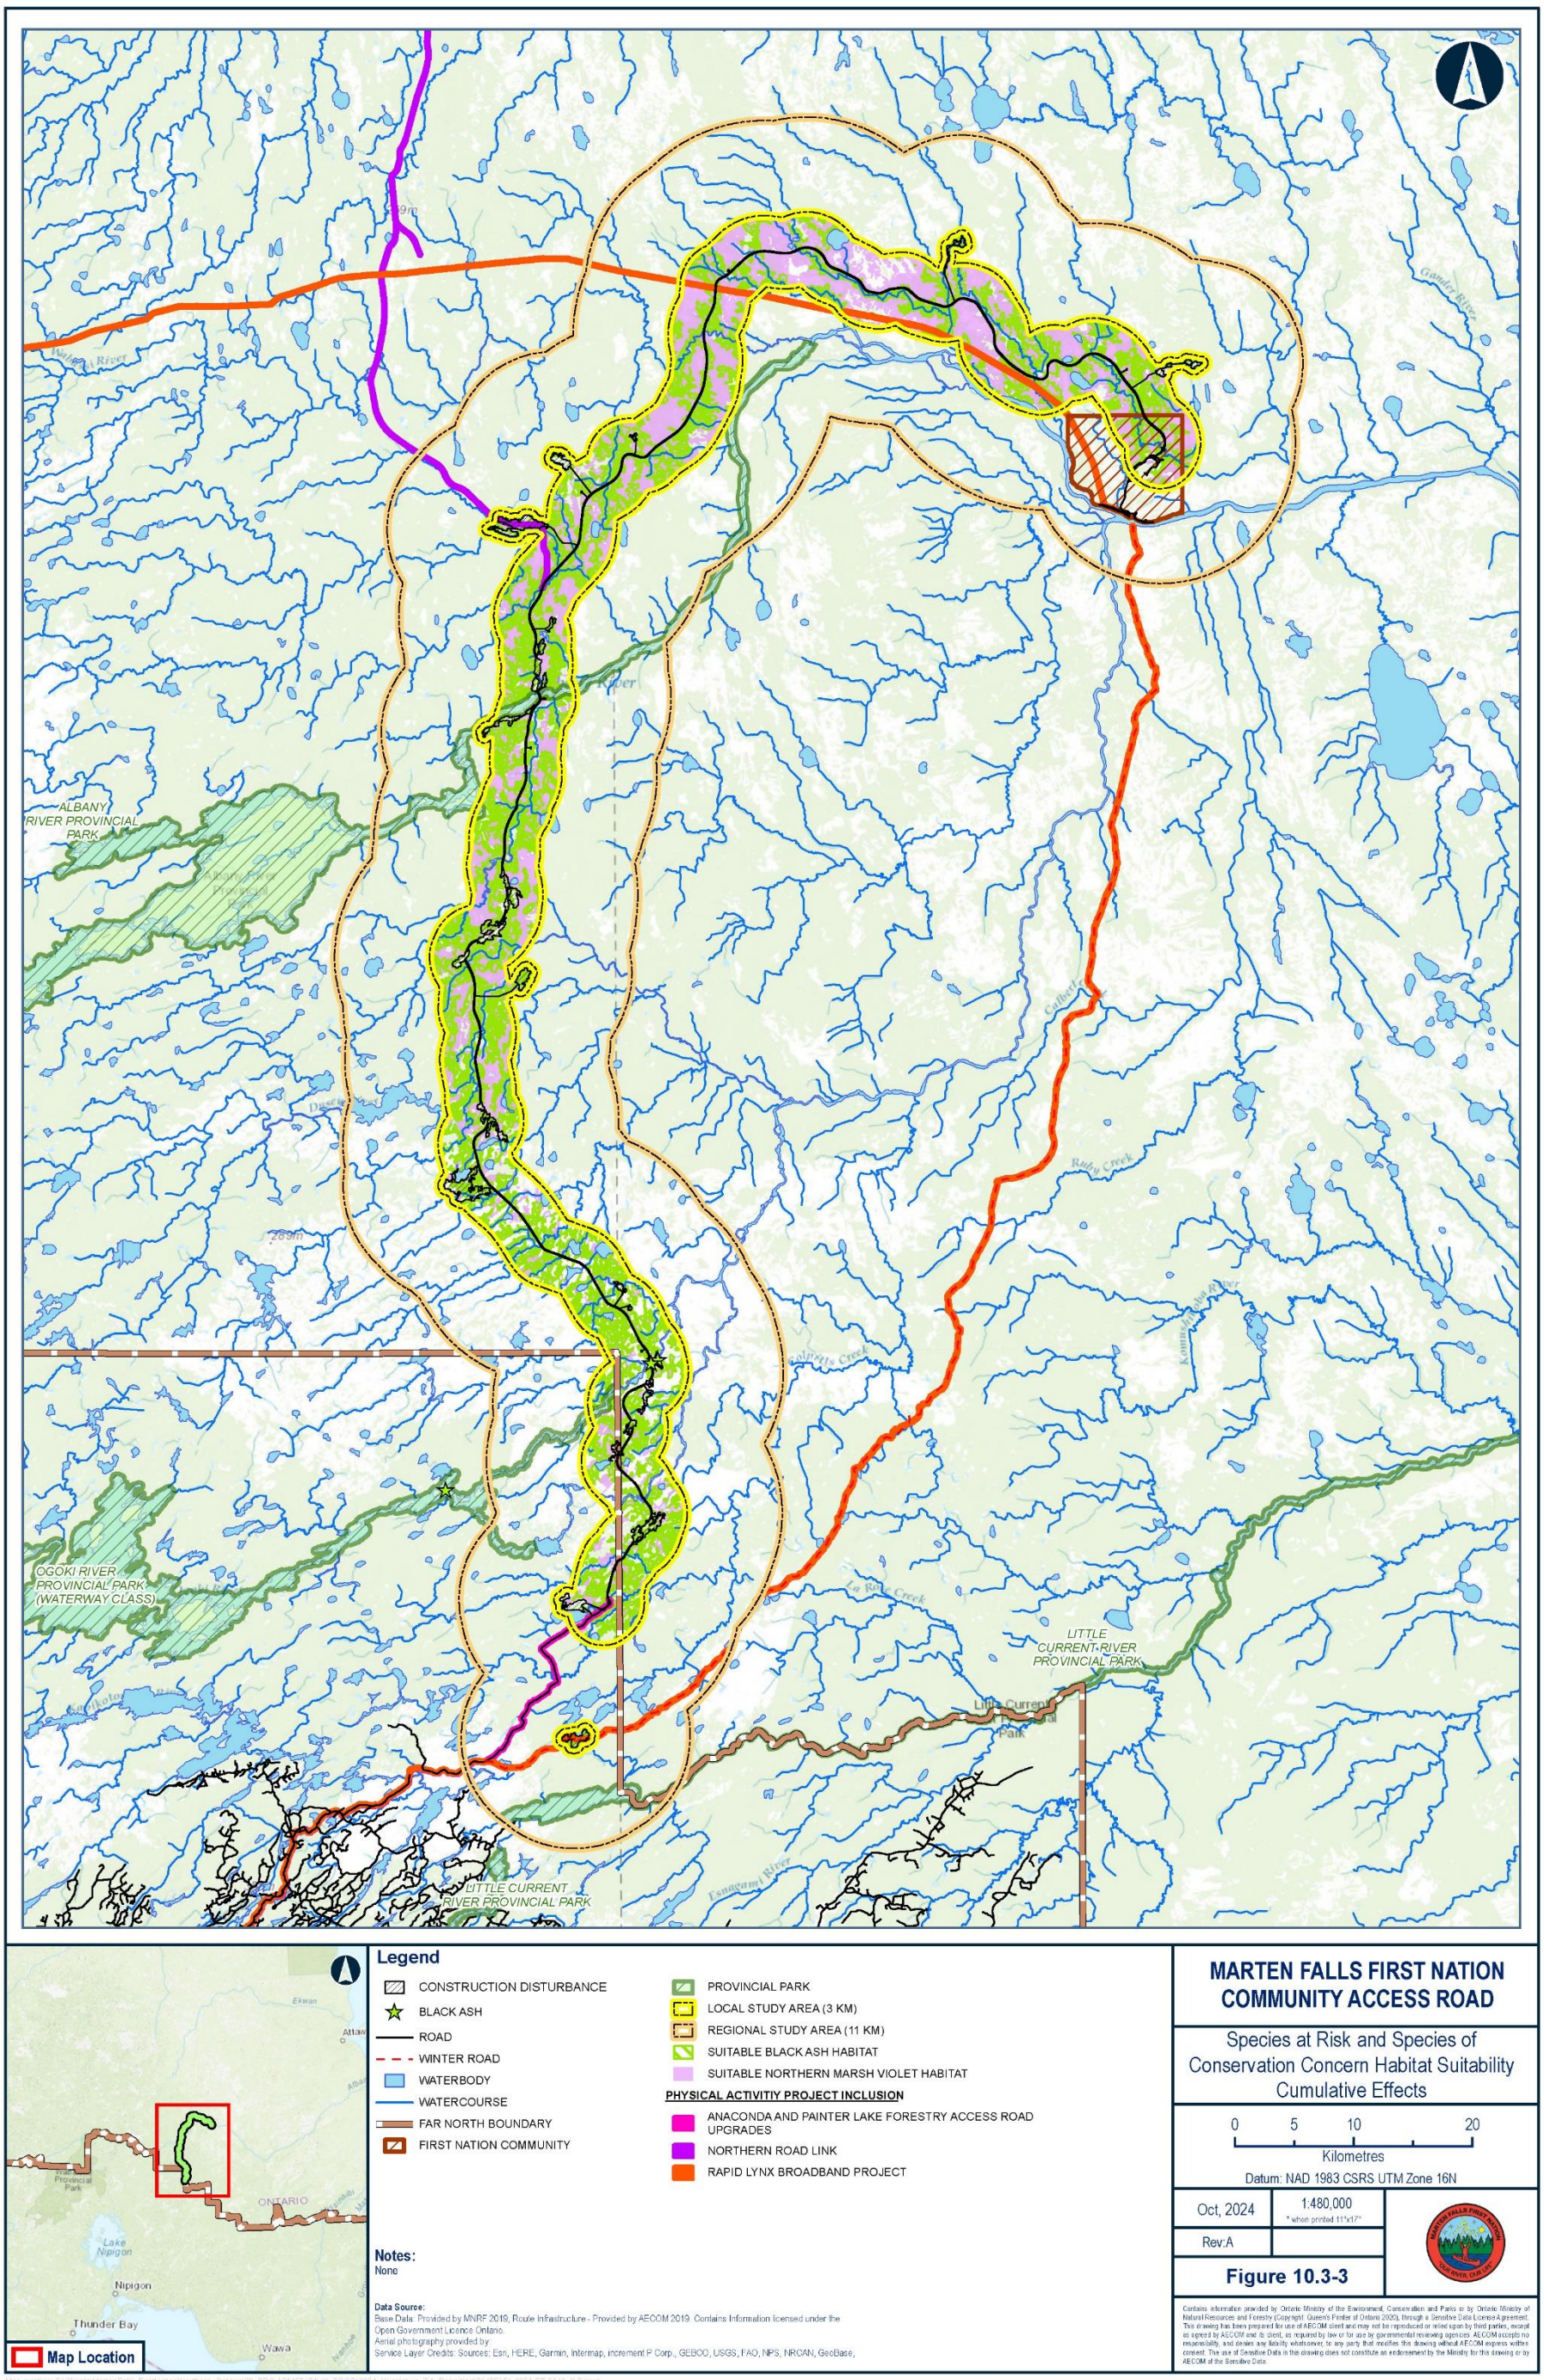

Figure 10.3-3: Species at Risk and Species of Conservation Concern Habitat Suitability Cumulative Effects

Effects from direct vegetation loss from the Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband projects will begin during construction of the Community Access Road and continue through operations of the Community Access Road.

Climate change has the potential to have negative effects on the availability, distribution, composition and function of vegetation valued components.

However, vegetation valued components are expected to remain abundant, intact, and well distributed across the effects assessment Regional Study Area. The contribution of the Community Access Road and other reasonably foreseeable developments to cumulative residual effects on vegetation valued components in the effects assessment Regional Study Area is not expected to change the self-sustaining and ecologically effective status of vegetation valued components.

10.3.2.2 Changes in Groundwater

The Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades may cause alterations to drainage patterns, recharge rates, and increased or decreased groundwater levels due to activities such as road construction through wetlands, changes to topography, short-term water-taking, pit / quarry dewatering, and discharge of water.

Due to the predicted similar aggregate requirements and residual effects of the Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades, it is not expected that there would be any additional pit or quarry development and dewatering in the areas where the projects overlap.

Due to the limited spatial and temporal overlaps of the Community Access Road and reasonably foreseeable developments, it is not generally expected that there would be any additional cumulative effects due to road construction in wetland areas for vegetation valued components.

As the Rapid Lynx Broadband project is anticipated to be buried approximately 1 metre underground and underneath waterbodies, only temporary and minimal changes in groundwater are expected during construction, which does not overlap temporally with the Community Access Road.

10.3.2.3 Fragmentation and Edge Effects

The Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project will create new

linear corridor for at least some portion of their alignments, introducing new fragmentation and edge effects on the landscape primarily in the northern and southern portions of the effects assessment Regional Study Area; therefore, resulting in additional vegetation loss.

The projects will introduce an additional 2,555.9 hectares of fragmentation and edge effects layered on the existing disturbance within the effects assessment Regional Study Area and the Community Access Road effects assessment Construction Disturbance Area footprint.

Climate change may have additional negative effects on the availability, distribution, composition, and function of vegetation valued components, although these effects are expected to occur even in the absence of further fragmentation and edge effects.

10.3.2.4 Fugitive Dust Emissions

Dust accumulation may locally and directly impact vegetation by smothering plant tissues, hindering gas exchange, and reducing photosynthesis by blocking sunlight (Hirano et al., 1995; Prajapati, 2012). Dust often contains metals or pollutants, which can leach into the soil, causing toxicity or nutrient imbalances in plants. This can also degrade plant health and alter plant species composition, structure, and biomass in affected areas.

Fugitive dust emissions are anticipated from construction activities from the Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades, such as land clearing, blasting, and infrastructure implementation, and traffic on the all-season and access roads. Effects from fugitive dust emissions will begin during construction of the Community Access Road and continue through operations.

It is assumed that the construction and operations of the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades will produce similar levels of dust and metal deposition as estimated for the Community Access Road, meaning that the projects are expected to result in an increased residual effect from fugitive dust emissions on vegetation valued components.

The effects related to climate change are uncertain, but probable to occur and may alter the processes that influence the availability and distribution of vegetation valued components.

10.3.2.5 Mitigation Measures

It is anticipated that the mitigation measures that will be implemented to minimize the effects from direct vegetation loss, changes to groundwater, fragmentation of edge

effects, and fugitive dust emissions during the construction and operation of the Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project will be similar to those implemented for the Community Access Road. Refer to **Section 9.4.2** for a complete description of the proposed mitigation measures for vegetation.

It is expected that the effectiveness of mitigation measures for these activities will be evaluated throughout construction and operations, and will be modified or enhanced as necessary through adaptive management.

As a best practice, it is suggested that the monitoring programs of the Community Access Road and any reasonably foreseeable developments share relevant monitoring data for areas where predicted effects may overlap.

10.3.2.6 Determination of Significance

Relative to existing conditions, vegetation valued components are expected to remain abundant, intact, and well distributed across the effects assessment Regional Study Area. The contribution of the Community Access Road and other reasonably foreseeable developments to cumulative residual effects on vegetation valued components in the Cumulative Effects Assessment is not expected to change the self-sustaining and ecologically effective status of vegetation valued components.

Residual cumulative effects on vegetation valued components were considered **not significant** as the residual effects were assessed to be negligible, low, or medium in magnitude and within the resilience limits and adaptive capacity of the existing vegetation valued components.

The exception to this result is for Wetland Ecosystems, and specifically peatland ecosystems that comprise a large component of Wetland Ecosystems. The cumulative residual effects to Wetland Ecosystems resulting from changes to groundwater are dependant on the success of the proposed mitigations, including the implementation of the “floating road” construction technique for crossing peatland ecosystems. While it is predicted that the contribution of the Community Access Road and other reasonably foreseeable developments to cumulative residual effects on Wetland Ecosystems in the effects assessment Regional Study Area are not expected to change the self-sustaining and ecologically effective status of Wetland Ecosystems, there is still a high level of uncertainty surrounding the Community Access Road’s cumulative residual effect on Wetland Ecosystems. As a result, a precautionary approach has been applied and cumulative residual effects on Wetland Ecosystems are predicted to be **significant**.

10.3.3 Wildlife

Six valued components with residual effects were carried forward to the wildlife valued component Cumulative Effects Assessment:

- Bats (little brown myotis and northern myotis);
- Furbearers (wolverine);
- Furbearers (American marten);
- Furbearers (beaver);
- Reptiles and amphibians; and
- Pollinating insects.

Changes from the Community Access Road and the other reasonably foreseeable developments will be mostly permanent; some temporary work areas may be reclaimed but most of the project footprints will remain disturbed. Effects from past, present, and reasonably foreseeable activities will begin during construction of the Community Access Road and continue through operations.

10.3.3.1 Bats (Little Brown Myotis and Northern Myotis)

The addition of the Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are expected to result in effects on little brown myotis and northern myotis from habitat loss and alteration, sensory disturbance, incidental take, fugitive dust emissions, changes to groundwater, and collisions with vehicles relative to existing conditions.

The Community Access Road and other reasonably foreseeable developments will result in the removal of 912 hectares of little brown myotis and northern myotis maternity roost habitat, representing 3.4 percent of the suitable maternity roost habitat in the cumulative effects Regional Study Area Although forest harvest is considered a temporary habitat loss, it is expected that continued forest harvest would reduce suitable mature forest and continue to add to the cumulative disturbance of bat roosting habitat.

Sensory disturbance (loud noises, lights, smells, dust, and human activity) associated with the construction and / or operations of the Community Access Road and other reasonably foreseeable developments could lead to reduced survivorship and / or reproductive success for little brown myotis and northern myotis occupying habitats near the project footprints, as bats may avoid the Community Access Road area and the areas within 100 metres of the footprints.

In addition, the effects related to climate change are uncertain but are mostly assumed to have an adverse influence on bat habitat.

However, it is predicted that the changes to little brown myotis and northern myotis habitat availability, distribution, and population survival and reproduction are expected to remain within the resilience and adaptability limits of the regional populations in the wildlife effects assessment Regional Study Area.

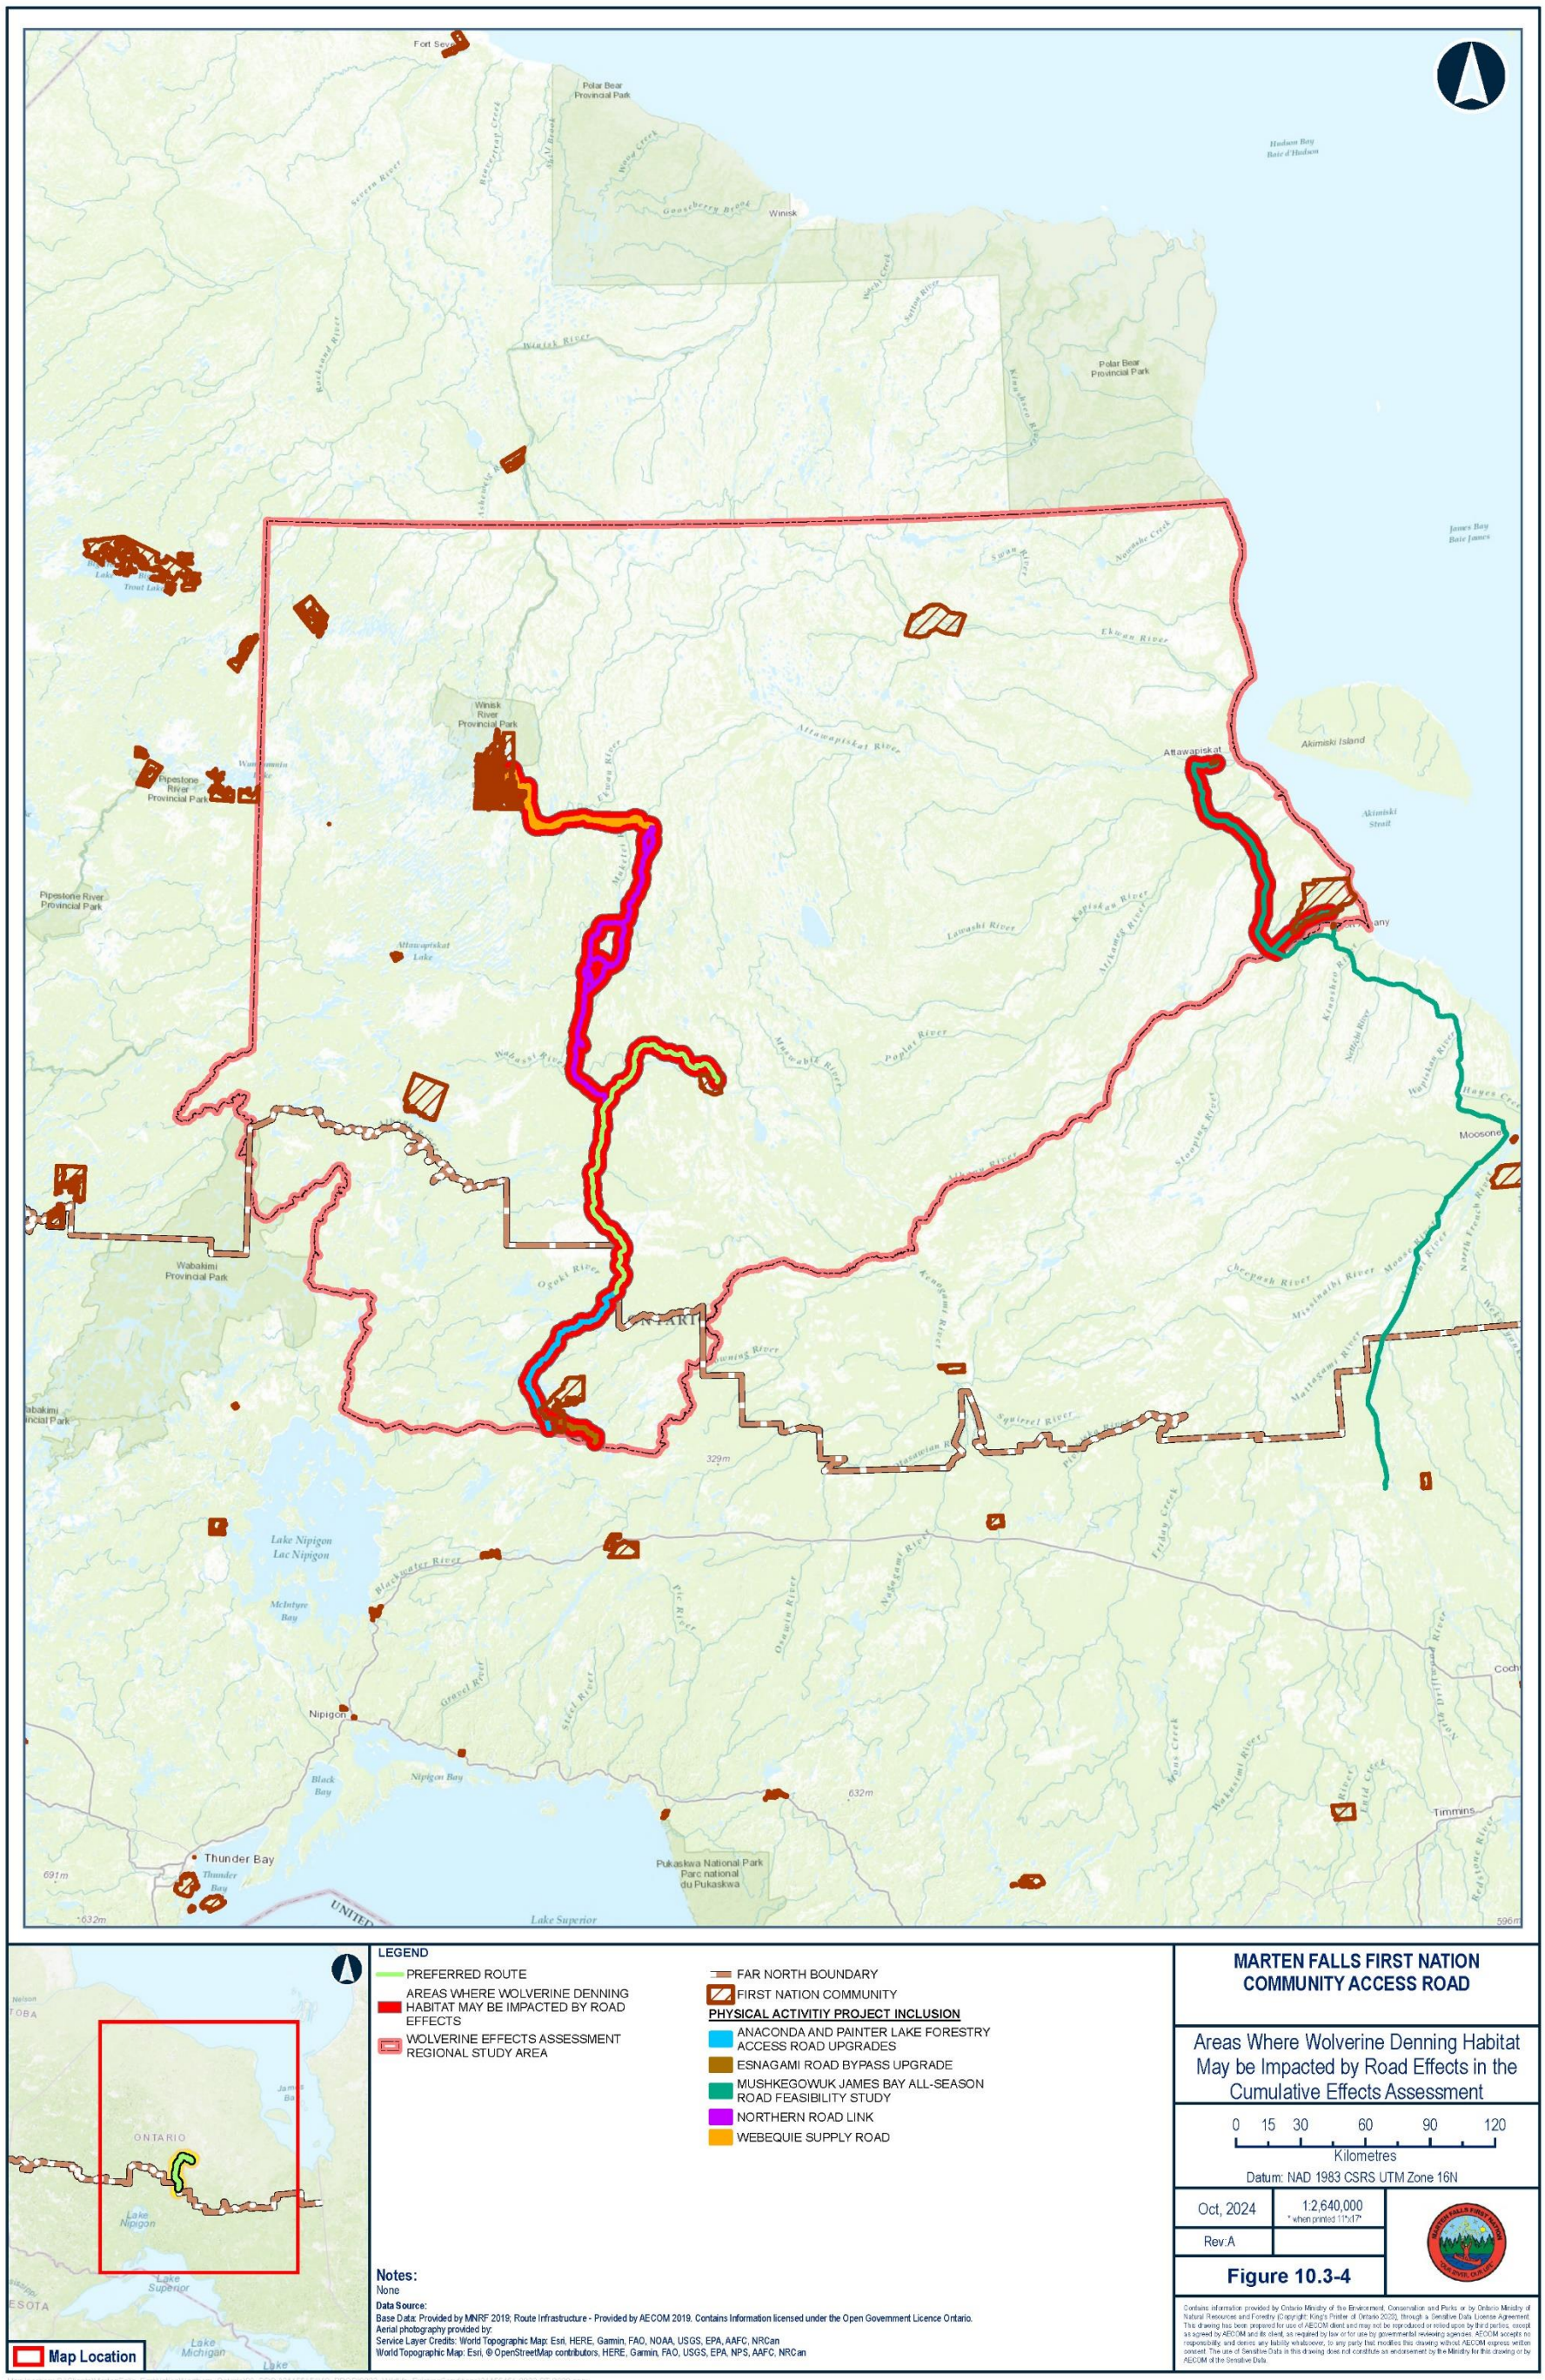
10.3.3.2 Furbearers (Wolverine)

The addition of the Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are expected to result in effects on wolverine from habitat loss and alteration, sensory disturbance, an increase in predator access, incidental take, collisions with vehicles and equipment, fugitive dust emissions, changes to groundwater, and an increase in public access relative to existing conditions.

Areas where wolverine denning habitat may be affected by road effects in the Cumulative Effects Assessment are shown on **Figure 10.3-4**.

The Community Access Road and the other reasonably foreseeable developments are predicted to remove 75,109 hectares of previously undisturbed habitat for wolverine. This represents a change of 0.47 percent of suitable habitat within the wolverine effects assessment Regional Study Area relative to existing conditions. Additionally, potential denning habitat within 4 kilometres of the road project are predicted to be indirectly affected by road effects.

Sensory disturbance (loud noises, lights, smells, dust, and human activity) associated with the construction or operations of the Community Access Road and other reasonably foreseeable developments are expected to affect wolverine habitat availability, distribution, and survival and reproduction through loss of quality denning habitat, general avoidance behaviour, changes to the quality and quantity of food resources as well as potential juvenile mortality, in areas within several kilometres of construction areas.



Incidental take of wolverines may occur as a result of either the destruction of dens or from collisions with vehicles, equipment, or public vehicles using the Community Access Road and other reasonably foreseeable developments or associated infrastructure.

In addition, the effects related to climate change are uncertain but are mostly assumed to have an adverse influence on wolverines.

Changes from the Community Access Road and the other reasonably foreseeable developments will be mostly permanent; some temporary work areas may be reclaimed but most of the project footprints will remain disturbed.

However, the wolverine population is expected to remain self-sustaining and ecologically effective in the wolverine effects assessment Regional Study Area after implementation of the Community Access Road and the other reasonably foreseeable developments.

Figure 10.3-4: Areas Where Wolverine Denning Habitat May be Impacted by Road Effects in the Cumulative Effects Assessment

10.3.3.3 Furbearers (American Marten)

The addition of the Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are expected to result in effects on American marten from habitat loss and alteration, sensory disturbance, an increase in predator access, incidental take, collisions with vehicles and equipment, fugitive dust emissions, changes to groundwater, and an increase in public access relative to existing conditions.

The Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are predicted to remove 4,870 hectares of moderate to high suitability habitat for American marten. This represents a change of 2.05 percent of suitable habitat.

Sensory disturbance (loud noises, lights, smells, dust, and human activity) associated with the construction or operations of the Community Access Road and the other reasonably foreseeable developments may affect American marten survival and reproduction through loss of quality denning habitat.

Incidental take of martens may occur as a result of the destruction of dens if work is conducted within the denning window (May to July). The cumulative effect of incidental take of American marten is possible if dens are removed or disturbed during denning season for the construction of the Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project.

The construction of the Community Access Road and the other reasonably foreseeable developments is anticipated to result in an increase in public access and may result in a subsequent increase in trapping effort and an increase in marten mortality in the areas surrounding the Community Access Road corridor and the Northern Road Link.

In addition to human activities, climate change may contribute cumulatively to changes in the quality, quantity, and distribution of American marten habitat, and marten survival and reproduction; however, the magnitude is uncertain.

Overall, the American marten population is expected to remain self-sustaining and ecologically effective in the wildlife effects assessment Regional Study Area after implementation of the Community Access Road and the other reasonably foreseeable developments.

10.3.3.4 Furbearers (Beaver)

The addition of the Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are

expected to result in effects on beaver from habitat loss and alteration, sensory disturbance, an increase in predator access, incidental take, collisions with vehicles and equipment, fugitive dust emissions, changes to groundwater, and an increase in public access relative to existing conditions.

The Community Access Road and the other reasonably foreseeable developments will result in the removal of 1,622 hectares of moderate to high suitability habitat for beaver, representing 1.22 percent of the suitable wetland beaver habitat in the wildlife effects assessment Regional Study Area available at existing conditions.

The construction of the Community Access Road and the other reasonably foreseeable developments is anticipated to result in an increase in public access that were not previously accessible by vehicle in existing conditions, resulting in a subsequent increase in trapping effort and an increase in beaver mortality in the areas surrounding the Community Access Road corridor and the Northern Road Link.

Additionally, climate change and related effects (including decreased wetland availability) may have continuous, permanent effects on beaver habitat availability that occur beyond the regional scale; however, the magnitude of changes due to climate change are uncertain.

Overall, the beaver population is expected to remain self-sustaining and ecologically effective in the wildlife effects assessment Regional Study Area after implementation of the Community Access Road and the other reasonably foreseeable developments.

10.3.3.5 Reptiles and Amphibians

The addition of the Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are expected to result in effects on reptiles and amphibians from habitat loss and alteration, sensory disturbance, incidental take, fugitive dust emissions, changes to groundwater, and collisions with vehicles and equipment relative to existing conditions.

The Community Access Road and other reasonably foreseeable developments will result in the removal of 3,806 hectares of wetland, representing 1.1 percent of the suitable wetland amphibian breeding habitat in the wildlife effects assessment Regional Study Area that are available at existing conditions.

Sensory disturbance (loud noises, lights, smells, dust, and human activity) associated with the construction and / or operations of the Community Access Road and other reasonably foreseeable developments are predicted to affect reptile and amphibian survival and reproduction through decreased reproductive success.

Incidental take may occur as a result of either the destruction of individuals through clearing and grubbing or from collisions with Project vehicles, equipment, or public vehicles using the Community Access Road, Northern Road Link, and upgraded Anaconda and Painter Lake Forestry Access Roads.

In addition, the effects related to climate change are uncertain but are mostly assumed to have continuous, permanent effects on reptile and amphibian habitat availability, survival and reproduction; however, magnitude is difficult to predict.

Overall, the reptile and amphibian populations are expected to remain self-sustaining and ecologically effective in the wildlife effects assessment Regional Study Area after implementation of the Community Access Road and the other reasonably foreseeable developments.

10.3.3.6 Pollinating Insects

The addition of the Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are expected to result in effects on pollinating insects from habitat loss and alteration, incidental take, fugitive dust emissions, changes to groundwater, and collisions with vehicles and equipment relative to existing conditions.

The Community Access Road and other reasonably foreseeable developments will result in the removal of 4,700 hectares of mostly undisturbed natural habitat, the majority of which is vegetated and provides foraging resources for pollinating insects.

Incidental take of pollinating insects may occur during the construction and operation as a result of either the destruction of individuals or bumblebee nest or bumblebee / beetle overwintering habitats through clearing and grubbing or from collisions with Project vehicles, equipment, or public vehicles using the Community Access Road, Northern Road Link, and upgraded Anaconda and Painter Lake Forestry Access Roads.

Additionally, climate change may have negative or positive effects on flowering plants and pollinators (elevated carbon dioxide, altered precipitation patterns, and warming temperatures); however, the magnitude is unknown.

Overall, the pollinating insect populations are expected to remain self-sustaining and ecologically effective in the wildlife effects assessment Regional Study Area after implementation of the Community Access Road and the other reasonably foreseeable developments.

10.3.3.7 Mitigation Measures

It is anticipated that avoidance and mitigation measures will be implemented to limit impacts to wildlife during the construction and operations of the Northern Road Link,

Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project and they will be similar to those implemented for the Community Access Road. Refer to **Section 9.4.3** for a complete description of the proposed mitigation measures for wildlife.

10.3.3.8 Determination of Significance

As mandated by the Impact Assessment Agency of Canada, determination of significance was predicted for cumulative effects on valued components that are species designated as threatened or endangered under Ontario's *Endangered Species Act* (Government of Ontario, 2007) or the federal *Species at Risk Act* (Government of Canada, 2002), and species of traditional / cultural importance to First Nations and as such are considered a part of Aboriginal Treaty Rights and Interests.

Significance was determined only for disciplines where it was required to meet federal or provincial requirements. For the purposes of this Cumulative Effects Assessment, significance of the effects for reptiles and amphibians and pollinating insects were not determined.

10.3.3.8.1 Bats

The regional little brown myotis and northern myotis populations are expected to remain self-sustaining and ecologically effective in the Cumulative Effects Assessment (in other words, there is no predicted change in the assessment endpoints). The anticipated changes to little brown myotis and northern myotis habitat availability, distribution, and survival and reproduction from the Community Access Road, other reasonably foreseeable developments, and climate change are expected to remain within the resilience and adaptability limits of the regional populations. The cumulative residual effects from the previous, existing, and reasonably foreseeable developments (including the Community Access Road) and climate change on little brown myotis and northern myotis are therefore considered **not significant** assuming the mitigation measures are implemented.

10.3.3.8.2 Wolverine

Regional wolverine populations may not remain self-sustaining and ecologically effective in the Cumulative Effects Assessment (in other words, there is a predicted change in the assessment endpoints). The anticipated changes to wolverine habitat availability, distribution, and survival and reproduction from the Project, other reasonably foreseeable developments, and climate change may not remain within the resilience and adaptability limits of the regional populations. Due to the high level of uncertainty (in other words, low prediction confidence), a precautionary approach was

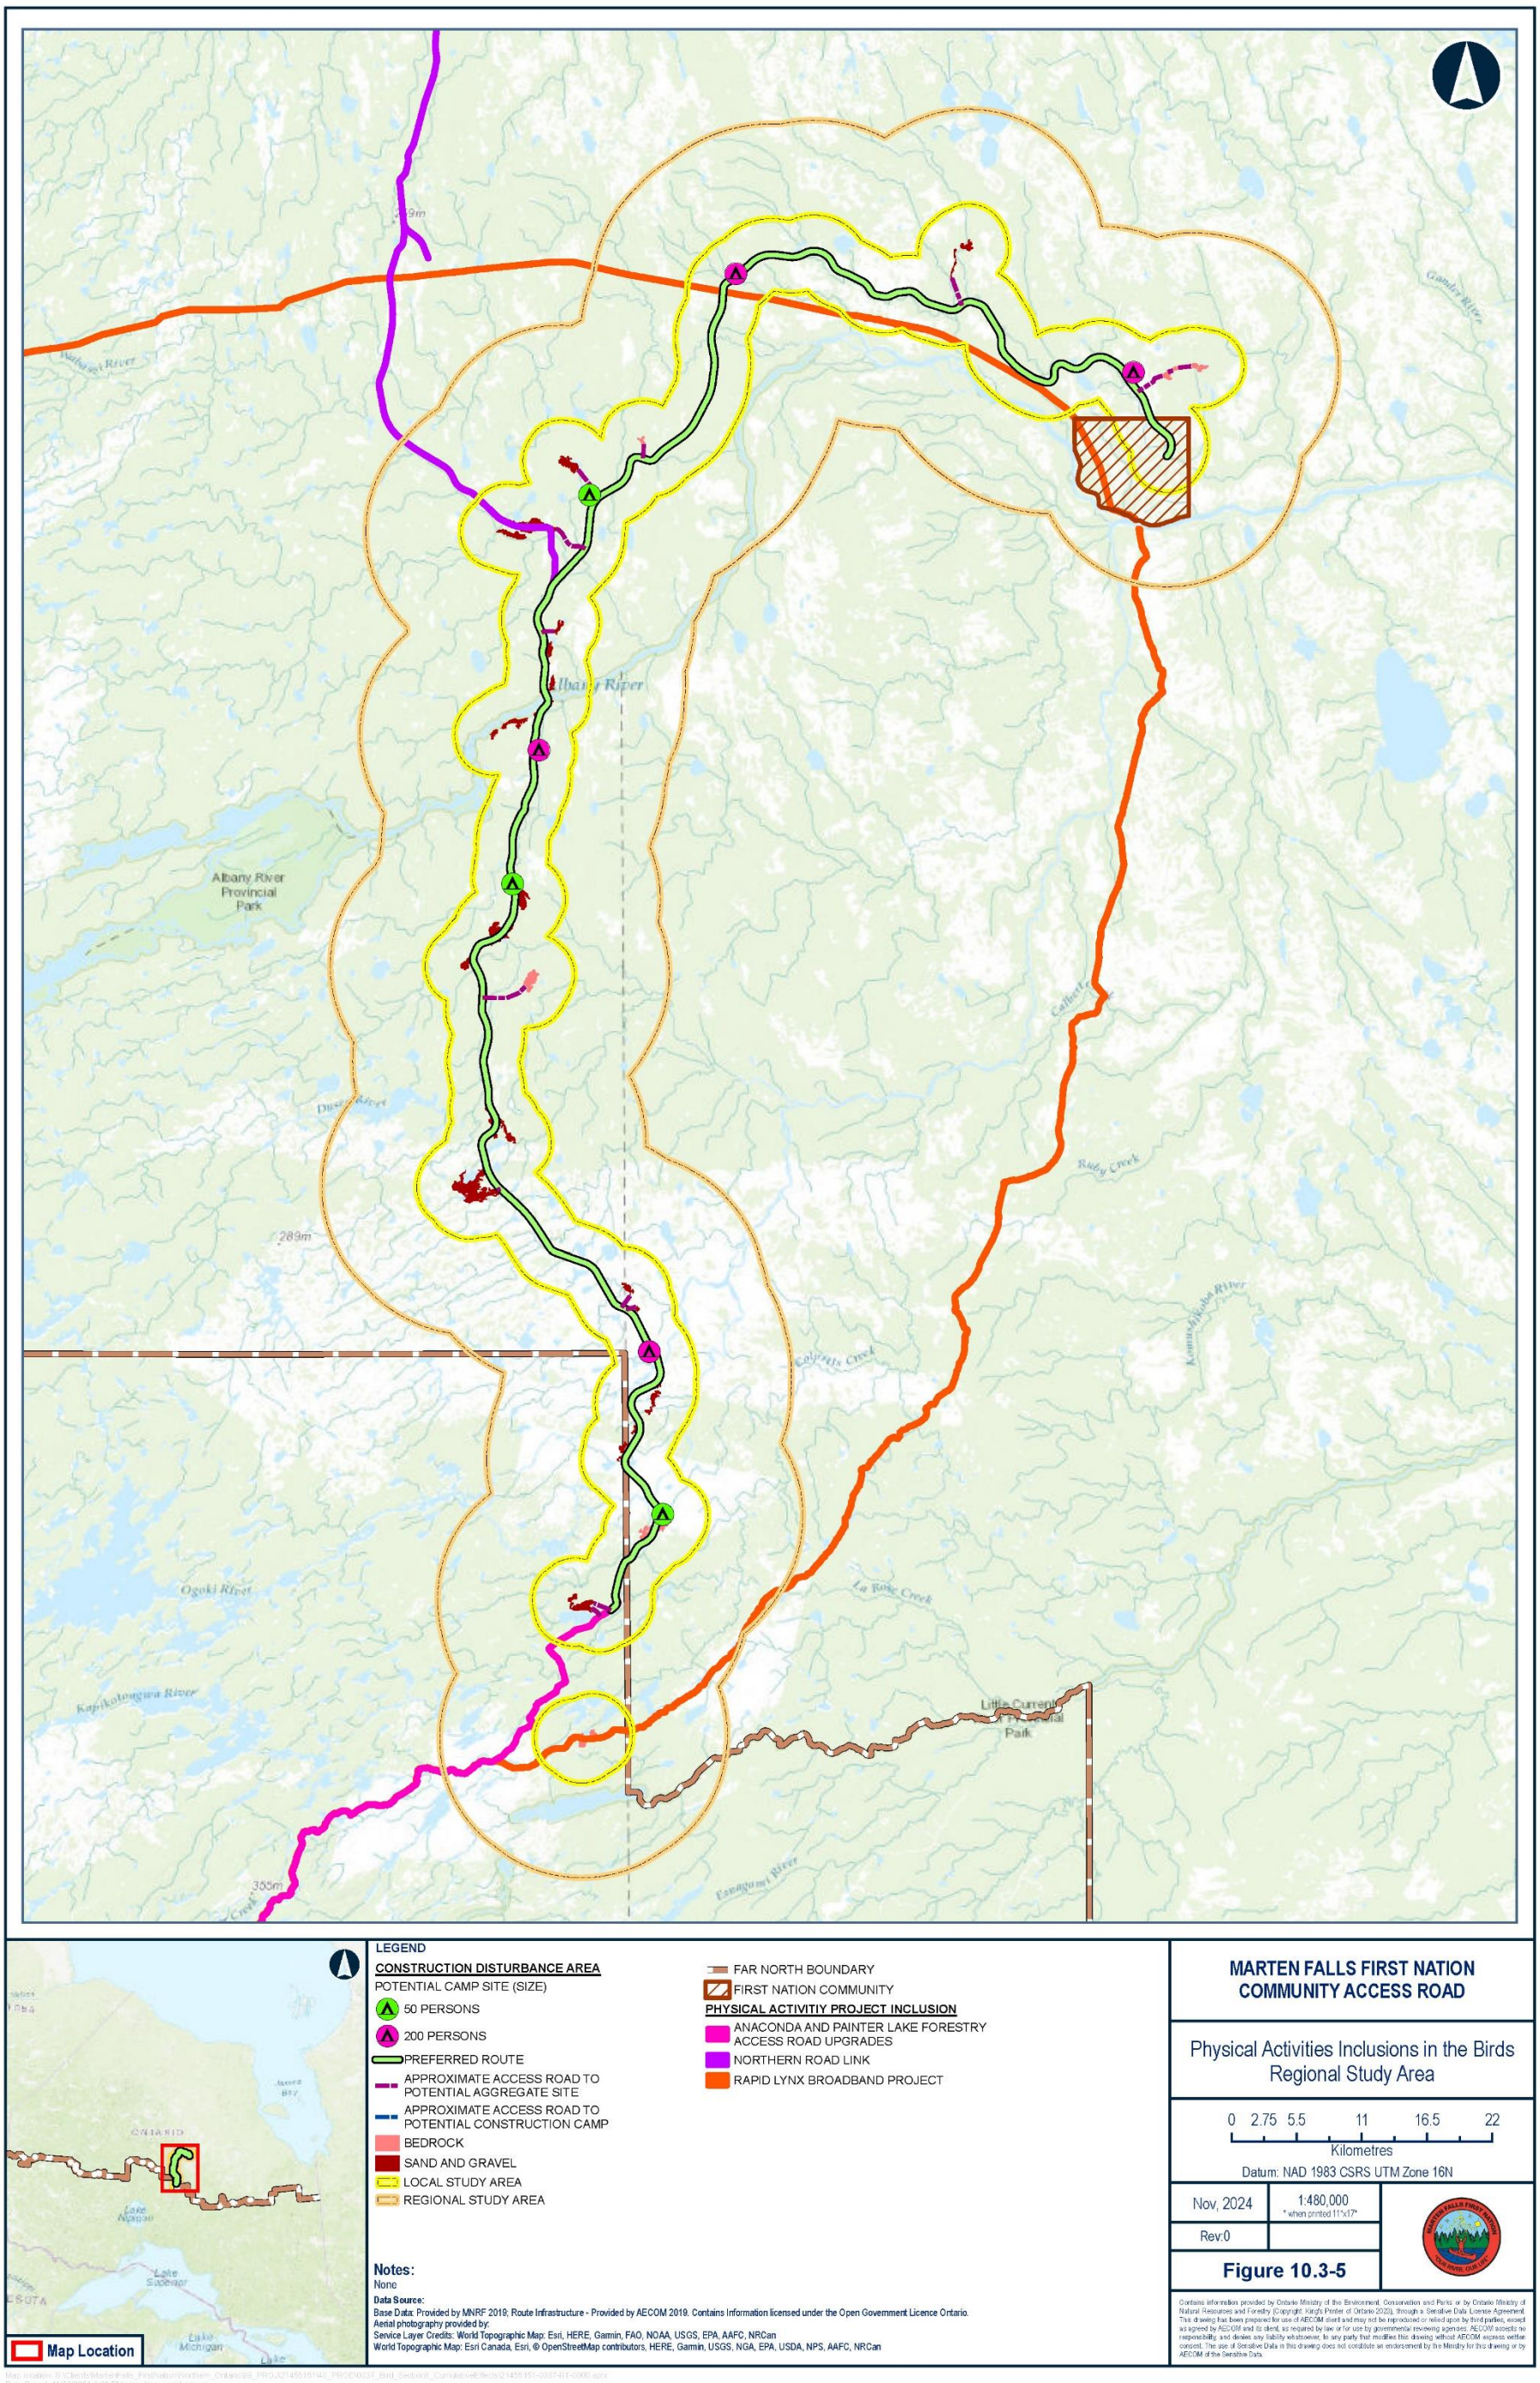
applied, and the cumulative residual effects from the previous, existing, and reasonably foreseeable developments (including the Project) and climate change on wolverines are therefore considered **significant**.

10.3.3.8.3 American Marten

Regional American marten populations are expected to remain to be self-sustaining and ecologically effective in the Cumulative Effects Assessment (in other words, there is no predicted change in the assessment endpoints). The anticipated changes to marten habitat availability, distribution, and survival and reproduction from the Project, other reasonably foreseeable developments, and climate change are expected to remain within the resilience and adaptability limits of the regional populations. The cumulative residual effects from the previous, existing, and reasonably foreseeable developments (including the Project) and climate change on American martens are therefore considered **not significant** assuming the mitigation measures are implemented.

10.3.3.8.4 Beaver

Regional beaver populations are expected to remain to be self-sustaining and ecologically effective in the Cumulative Effects Assessment (in other words, there is no predicted change in the assessment endpoints). The anticipated changes to beaver habitat availability, distribution, and survival and reproduction from the Project, other reasonably foreseeable developments, and climate change are expected to remain within the resilience and adaptability limits of the regional populations. The cumulative residual effects from the previous, existing, and reasonably foreseeable developments (including the Project) and climate change on beavers are therefore considered **not significant** assuming the mitigation measures are implemented.



10.3.4 Birds

Five valued components with residual effects were carried forward to the birds valued components Cumulative Effects Assessment:

- Changes to groundwater;
- Dust deposition;
- Habitat loss and alteration;
- Sensory disturbance; and
- Increase in edge habitat.

The locations of the projects considered for the Cumulative Effects Assessment in relation to the birds Regional Study Area are shown on **Figure 10.3-5**.

Figure 10.3-5: Physical Activities Inclusions in the Birds Regional Study Area

10.3.4.1 Changes to Groundwater

The Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades may cause alterations to drainage patterns, recharge rates and increased or decreased groundwater levels due to activities such as road construction through wetlands, changes to topography, short-term water-taking, pit / quarry dewatering and discharge of water, thereby affecting bird habitat availability and distribution.

Due to the predicted similar aggregate requirements and residual effects of the Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades, it is not expected that there would be any additional pit or quarry development and dewatering in the areas where the projects overlap.

Due to the limited spatial and temporal overlaps of the Community Access Road and reasonably foreseeable developments, it is not expected that there would be any additional cumulative effects due to road construction in peatland areas. There may be potential for additional cumulative effects beyond the predicted residual effects levels in the area where the Community Access Road and the Northern Road Link would meet if they both cross the same peatland area.

Overall, the anticipated changes to bird valued component habitat availability and distribution from changes to groundwater quantity are expected to remain within the resilience and adaptability limits of the regional populations, bird valued component are predicted to remain self-sustaining and ecologically effective.

10.3.4.2 Dust Deposition

Accumulation of airborne dust produced from the Community Access Road and other reasonably foreseeable developments may result in direct, localized changes to vegetation, possibly altering plant species composition, structure, and biomass. As a result, dust generated by construction activities could adversely affect birds by degrading habitat quality and forage availability and distribution.

Dust accumulation is expected to occur during construction and operations of the Community Access Road, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project, and may result in direct, localized changes to vegetation.

However, the anticipated changes to bird valued component habitat availability and distribution from dust deposition from reasonably foreseeable developments are

expected to remain within the resilience and adaptability limits of the regional populations. Bird valued components are predicted to remain self-sustaining and ecologically effective after cumulative effects dust deposition on habitat from reasonably foreseeable developments.

10.3.4.3 Habitat Loss and Alteration

The Community Access Road, Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and Rapid Lynx Broadband project are predicted to remove high suitability and moderate suitability breeding habitat for a number of bird species.

Effects from habitat loss from the Anaconda and Painter Lake Forestry Access Road upgrades and Rapid Lynx Broadband project are assumed to begin prior to construction of the Community Access Road and continue through operations of the Community Access Road. Effects from habitat loss from the Northern Road Link are assumed to begin and continue through operations of the Community Access Road.

Additionally, climate change may increase temperatures, the frequency and severity of wildfires, and insect outbreaks, all of which may affect the condition of boreal forest ecosystems; however, the magnitude of impacts from climate change are unknown.

The bird species included as part of this Cumulative Effects Assessment are predicted to remain self-sustaining and ecologically effective with the implementation of the Community Access Road and other reasonably foreseeable developments.

Overall, the anticipated changes to bird habitat availability, distribution, and survival and reproduction due to habitat loss and alteration from the Community Access Road and other reasonably foreseeable developments are expected to remain within the resilience and adaptability limits of the regional population.

10.3.4.4 Sensory Disturbance

Sensory disturbance during construction and operations of the reasonably foreseeable developments could result in the indirect loss or degradation of suitable habitat if individuals avoid areas with sensory disturbance.

Sensory disturbance effects from all reasonably foreseeable developments may overlap construction of the Community Access Road. Sensory disturbance will only occur during construction of the Rapid Lynx Broadband project, unless maintenance of the broadband cable is required during operations.

Bird valued components are predicted to remain self-sustaining and ecologically effective with the implementation of the Community Access Road and other reasonably foreseeable developments. Overall, the anticipated changes to bird habitat availability, distribution, and survival and reproduction due to sensory disturbance from the Community Access Road and other reasonably foreseeable developments are expected to remain within the resilience and adaptability limits of the regional population.

10.3.4.5 Increase in Edge Habitat

The creation of forest edge due to the construction of the Community Access Road, Northern Road Link, and Rapid Lynx Broadband project may facilitate predator movement and access to nests in adjacent forest habitats. However, anticipated increases in predation risk due to increased edge habitat are expected to be relatively small.

Changes to predation risk due to increased edge habitat from construction of reasonably foreseeable developments are not expected to have a measurable effect on bird survival and reproduction for the populations in the in the Cumulative Effects Assessment Regional Study Area.

10.3.4.6 Mitigation Measures

It is anticipated that the mitigation measures that will be implemented to limit changes to groundwater quality, habitat loss, sensory disturbance and increase in edge habitat during the construction and operation of the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades will be similar to those implemented for the Community Access Road. Refer to **Section 9.4.4** for a complete description of the proposed mitigation measures for birds.

As a best practice, it is suggested that the monitoring programs of the Community Access Road and any reasonably foreseeable developments share relevant monitoring data for areas where predicted effects may overlap.

10.3.4.7 Determination of Significance

As mandated by the Impact Assessment Agency of Canada, determination of significance was predicted for cumulative effects on valued components that are species designated as threatened or endangered under federal *Species at Risk Act* (Government of Canada, 2002),and species of traditional / cultural importance to First Nations and as such are considered a part of Aboriginal Treaty Rights and Interests.

The bird species included as part of this Cumulative Effects Assessment are predicted to remain self-sustaining and ecologically effective with the implementation of the

Community Access Road and other reasonably foreseeable developments. Overall, the anticipated changes to bird habitat availability, distribution, and survival and reproduction due to habitat loss and alteration from the Community Access Road and other reasonably foreseeable developments are expected to remain within the resilience and adaptability limits of the regional population. The cumulative residual effects from previous, existing, and reasonably foreseeable developments (including the Community Access Road) are therefore considered **not significant**.

However, climate change may have significant effects on the bird populations beyond the Cumulative Effects Assessment Regional Study Area if temperatures increase by 1.5 degrees Celsius to 3.0 degrees Celsius relative to current conditions.

10.3.5 Ungulates

Two valued components with residual effects were carried forward to the ungulates Cumulative Effects Assessment:

- Boreal caribou; and
- Moose

10.3.5.1 Boreal Caribou

The Community Access Road, past, present, and reasonably foreseeable developments are predicted to have the following cumulative effects on boreal caribou:

- Additional 290,662 hectares of new disturbance in the boreal caribou effects assessment Regional Study Area. This is expected to increase the proportion of total disturbance (anthropogenic and natural combined) in the caribou effects assessment Regional Study Area from 24.3 percent to 25.7 percent.
- Additional 116,729 hectares of anthropogenic disturbance in the Missisa range. This is expected to increase the proportion of total disturbance (anthropogenic and natural combined) in the Missisa range from 6.2 percent to 7.7 percent.
- Additional 5,654 hectares of permanent disturbance in the Nipigon range. This is expected to increase the proportion of total disturbance in the Nipigon range from 45.8 percent to 45.9 percent.
- Additional 169,601 hectares of new anthropogenic disturbance in the Ozhiski range. This is expected to increase the proportion of total disturbance (anthropogenic and natural combined) in the Ozhiski range from 24.5 percent to 28.6 percent.

- Additional 154 hectares of permanent disturbance in the Pagwachuan range. This is expected to increase the proportion of total disturbance (anthropogenic and natural combined) in the Pagwachuan range by less than 0.01 percent.
- Sensory disturbance (noise, smells, light spill, human presence) are expected to reduce habitat quality and elicit avoidance by boreal caribou in proximity of the Construction Disturbance Area of each respective project.
- Linear disturbances may result in physical and perceived barriers to movement for boreal caribou, particularly in the Missisa and Ozhiski ranges, where boreal caribou are naïve to permanent road disturbances and may demonstrate strong avoidance behaviours.
- Introduction of linear corridors expected to be used by predators and the public to facilitate access to areas that are less accessible in the existing environment.
- Introduction of roads (all-season roads, temporary and permanent access roads), are expected to increase the risk of boreal caribou collisions with vehicles and equipment.
- Dust deposition is predicted to degrade vegetation in areas immediately adjacent to the Community Access Road and past, present, and reasonably foreseeable developments.
- Potential for alterations to drainage patterns, and increase or decrease of groundwater levels, thereby affecting boreal caribou habitat availability and distribution.

Cumulative effects on habitat for boreal caribou are shown on **Figure 10.3-6**. Predicted habitat quality in the boreal caribou Regional Study Area during the Cumulative Effects Assessment are show on **Figure 10.3-7** to **Figure 10.3-11**.

Cumulative effects to boreal caribou will begin during construction of the Community Access Road and continue through operations. Some changes that occur in the arrangement and connectivity of habitat will be permanent for all-season road projects where operations are indefinite, while other projects have temporary operations and are expected to be restored.

In addition, the effects related to climate change are uncertain but are mostly assumed to have an adverse influence on boreal caribou.

Figure 10.3-6: Anthropogenic Disturbance in the Boreal Caribou Regional Study Area during the Cumulative Effects Assessment

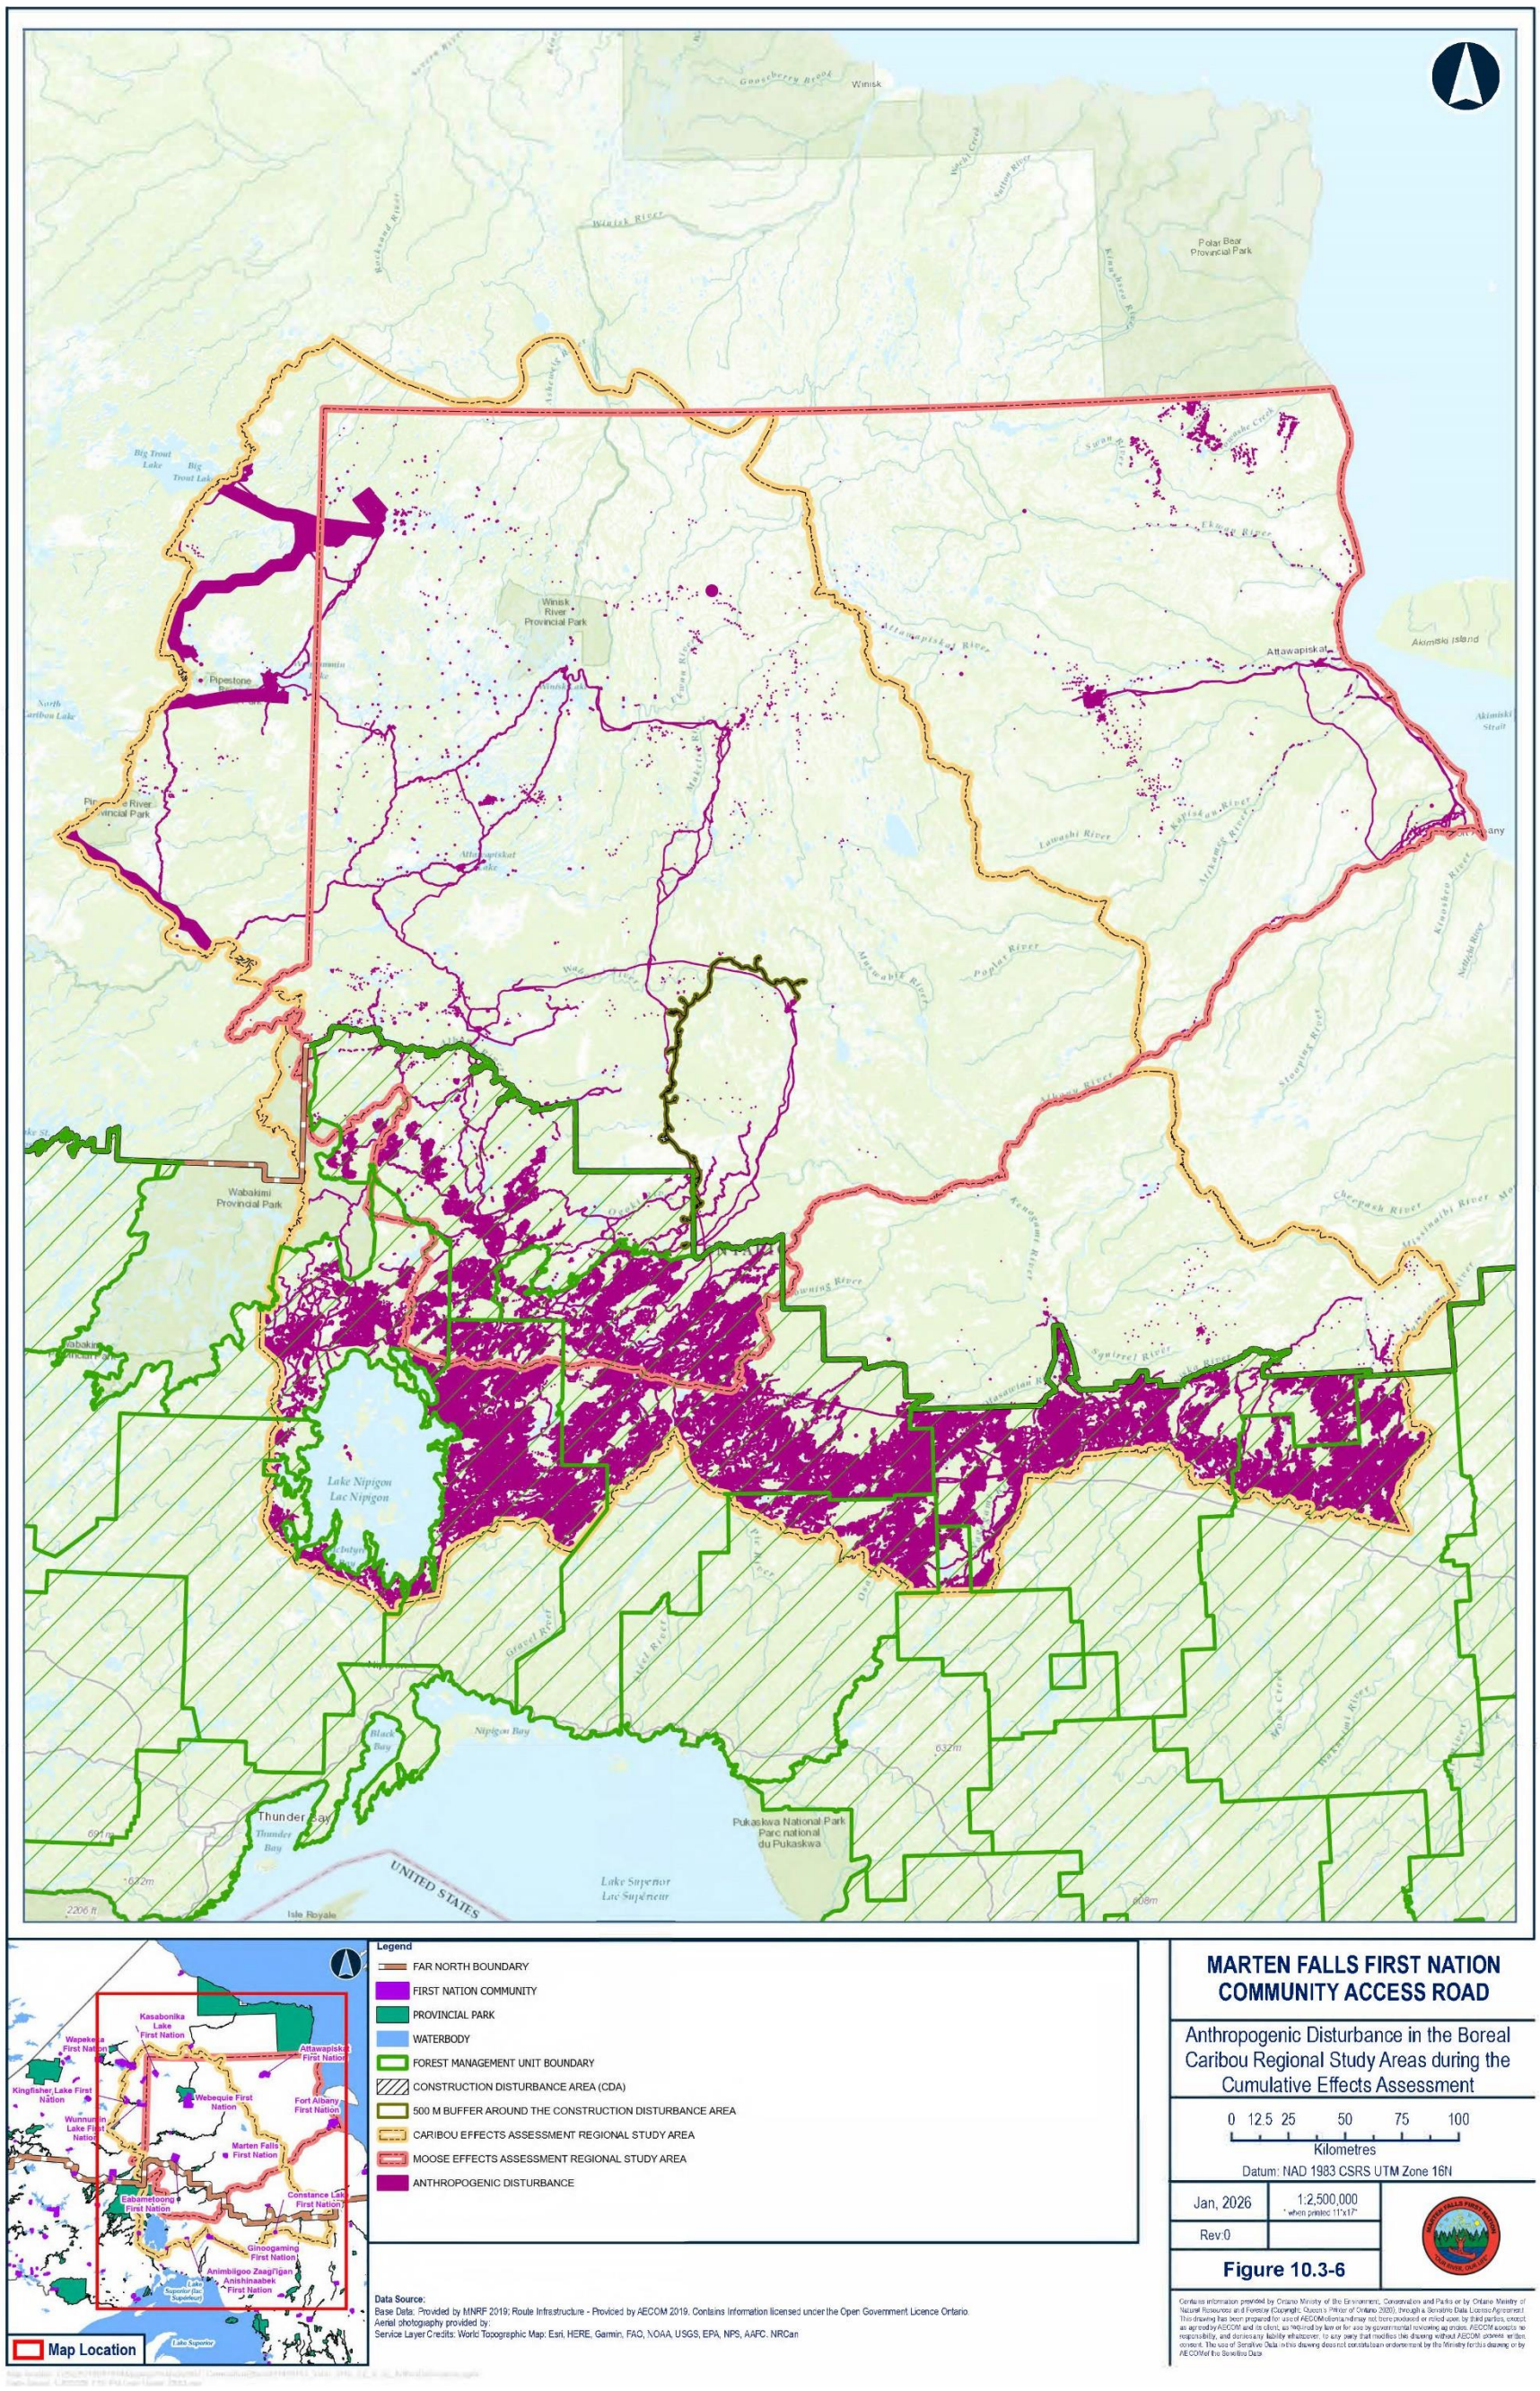


Figure 10.3-7: Predicted Habitat Quality during Calving Season in the Boreal Caribou Regional Study Area During the Cumulative Effects Assessment

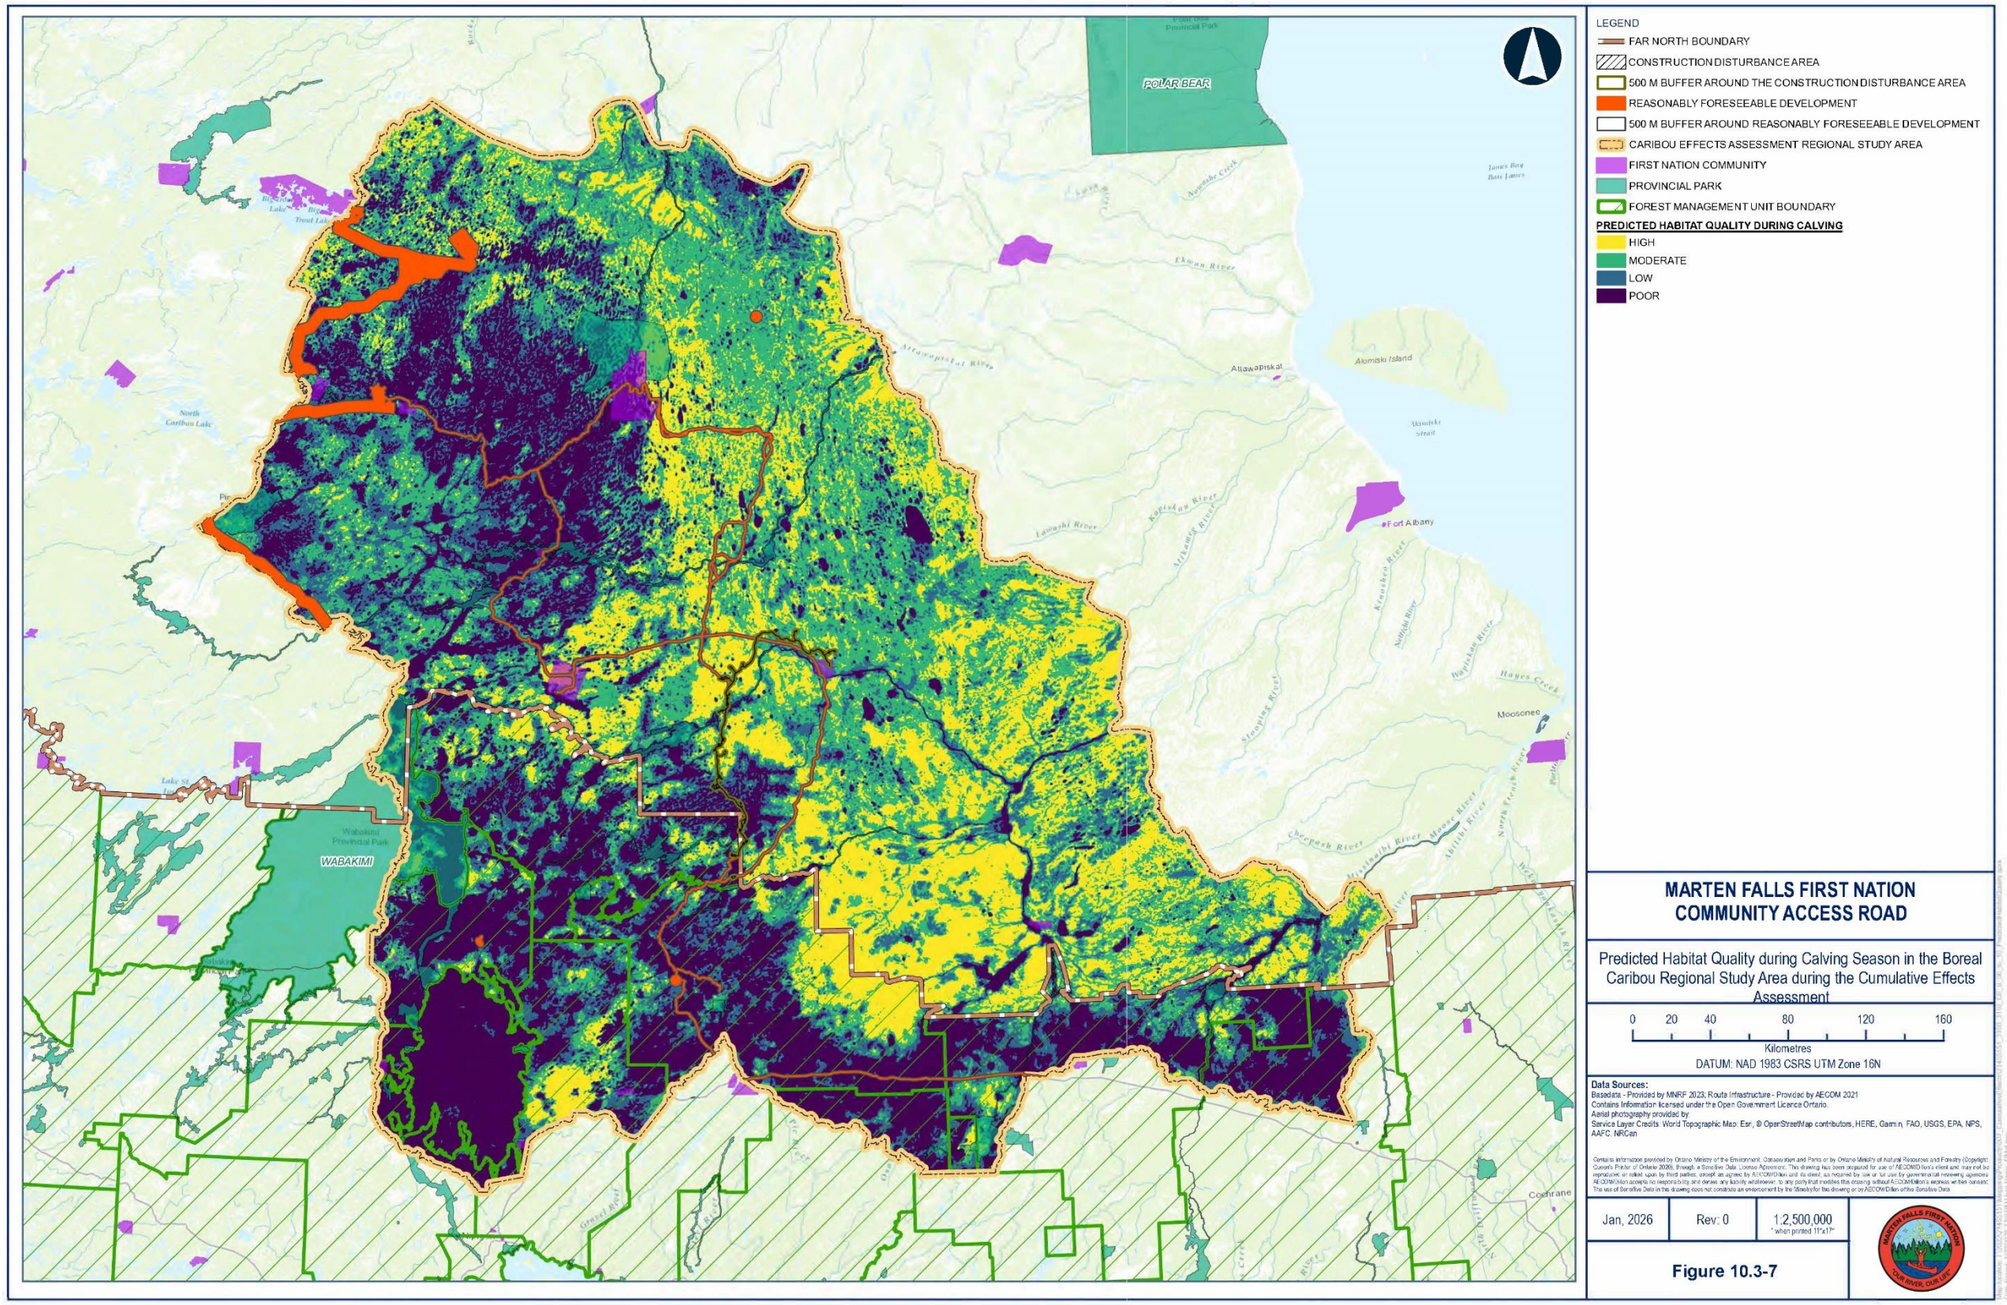

Figure 10.3-8: Predicted Habitat Quality during Summer Season in the Boreal Caribou Regional Study Area During the Cumulative Effects Assessment

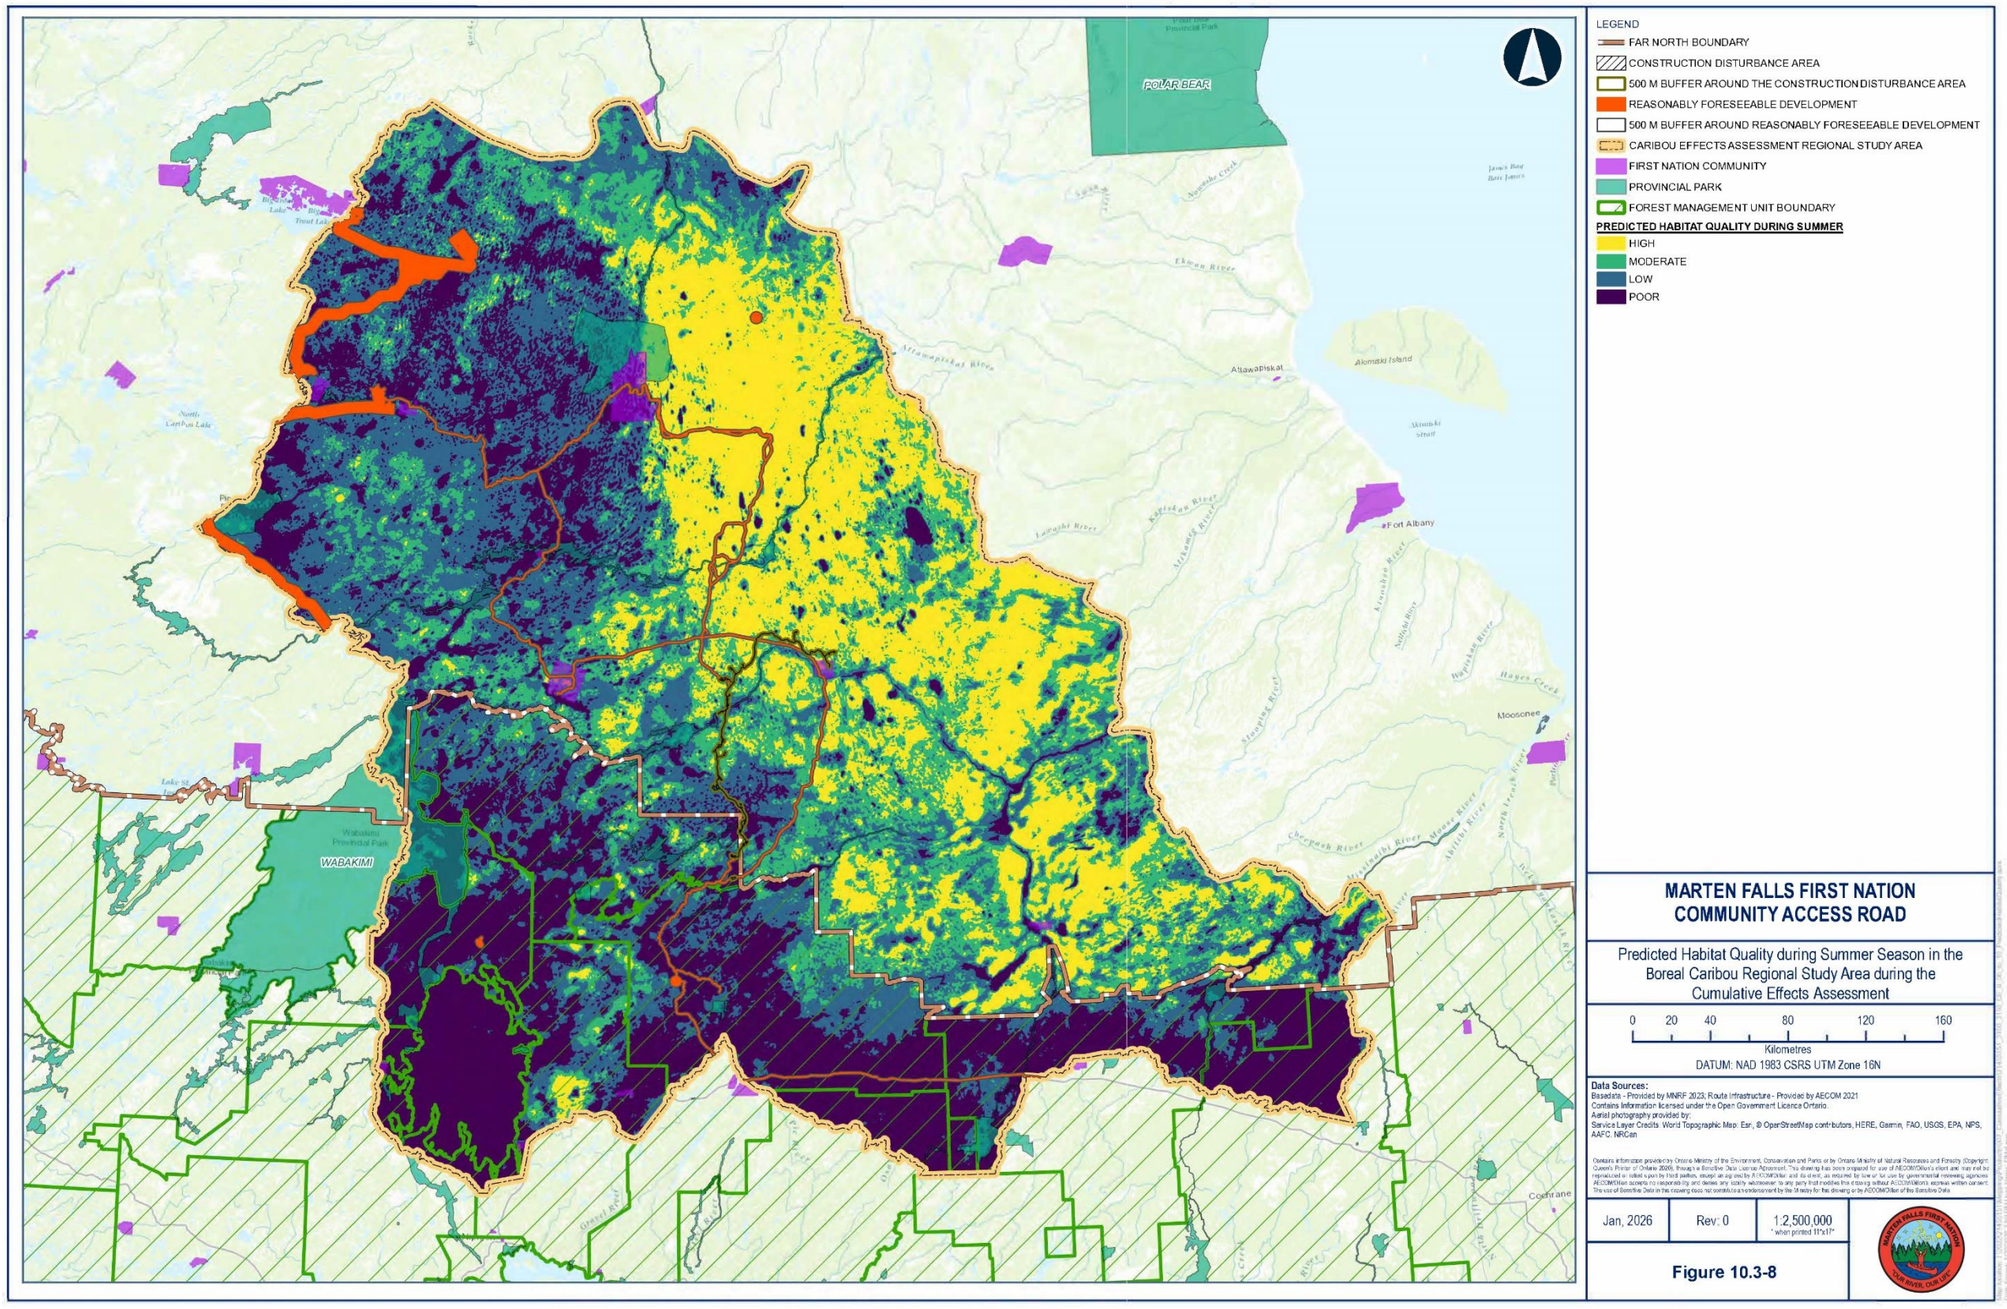

Figure 10.3-9: Predicted Habitat Quality during Fall Season in the Boreal Caribou Regional Study Area During the Cumulative Effects Assessment

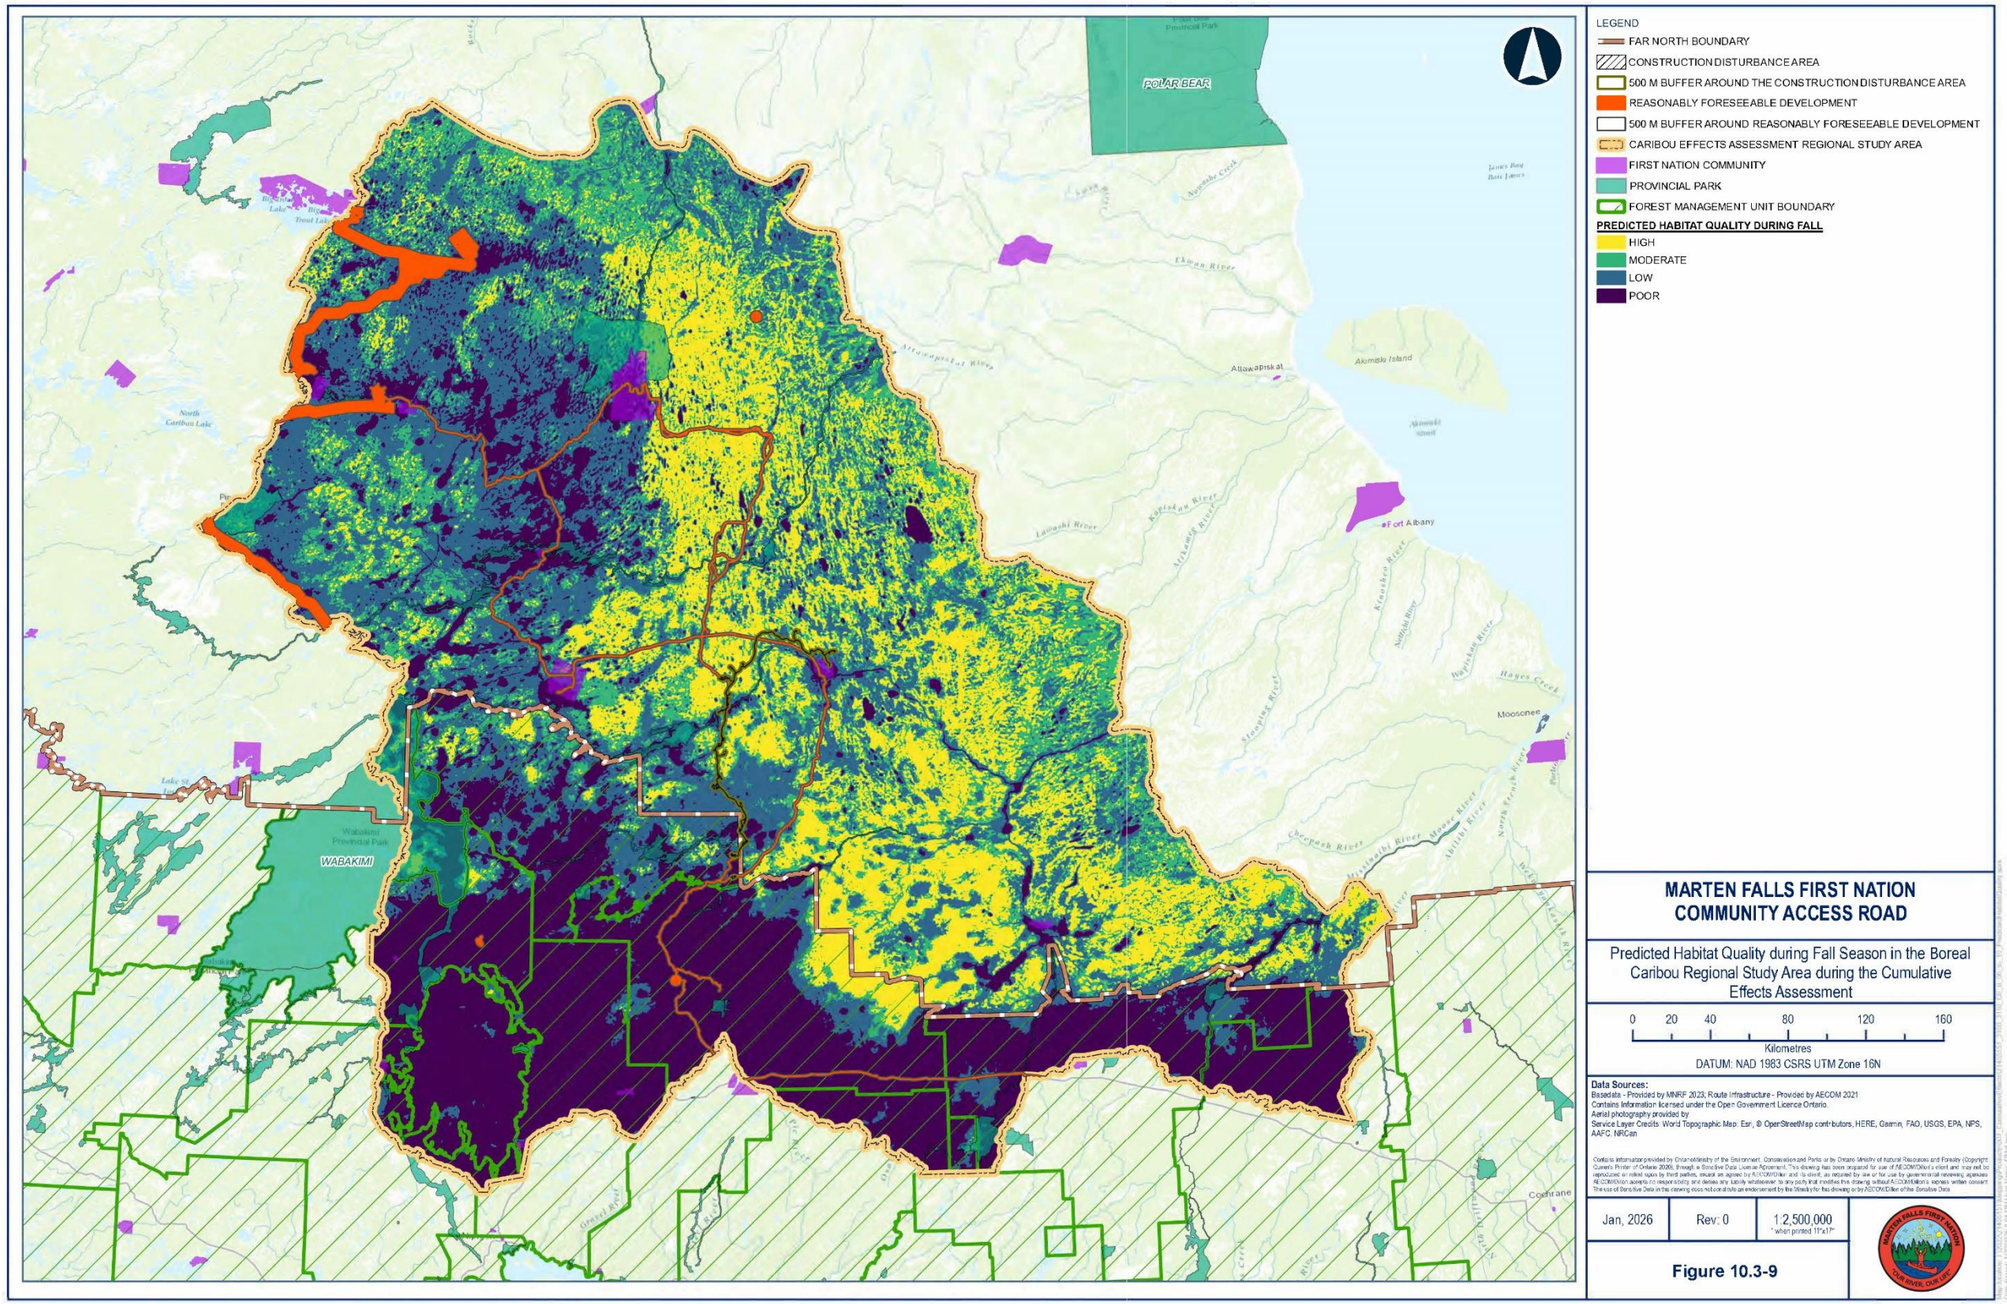

Figure 10.3-10: Predicted Habitat Quality during Winter Season in the Boreal Caribou Regional Study Area During the Cumulative Effects Assessment

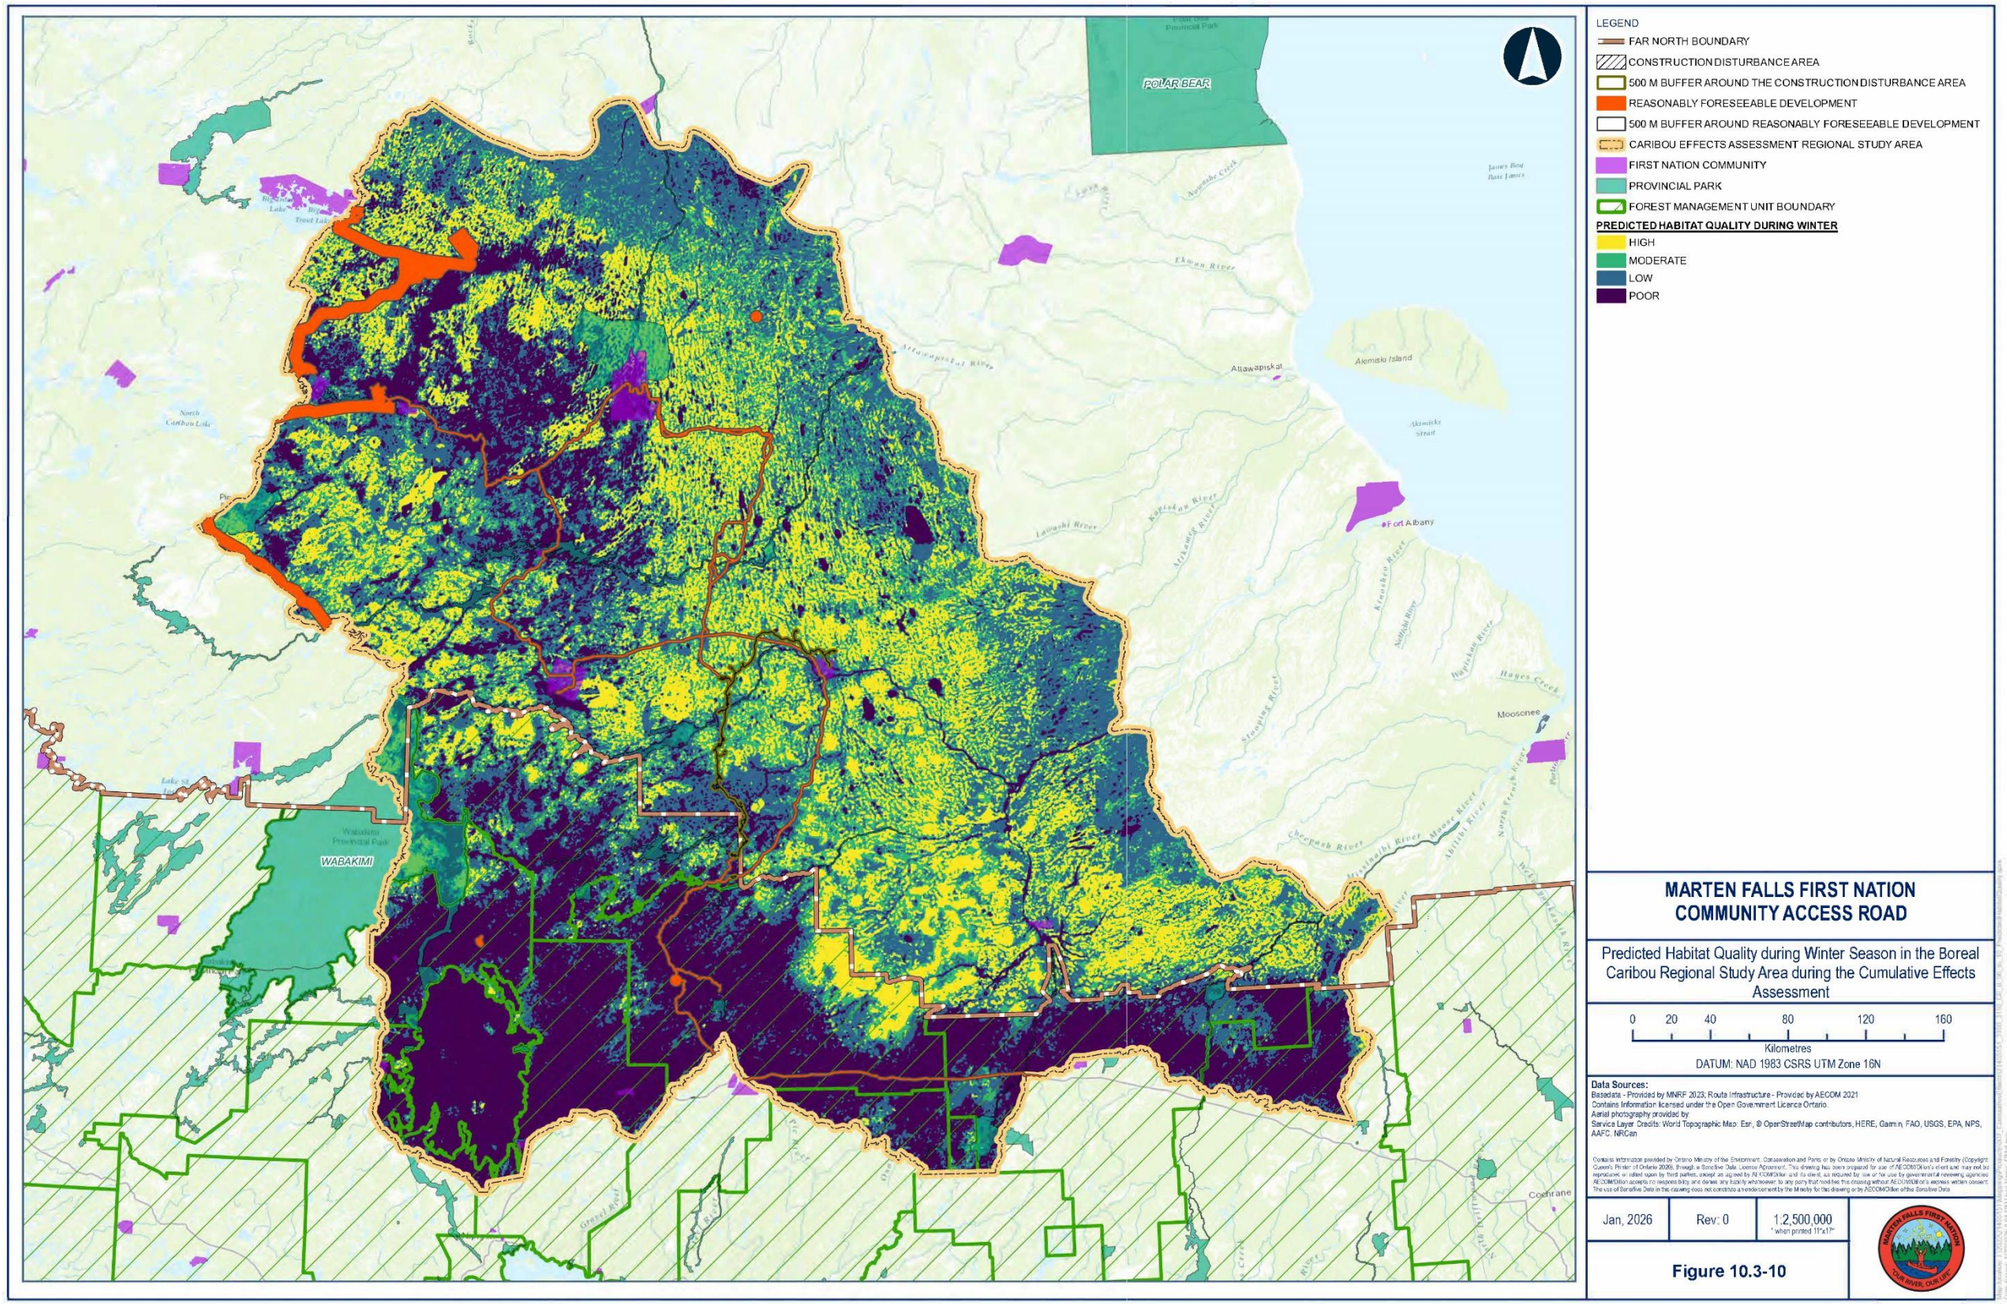

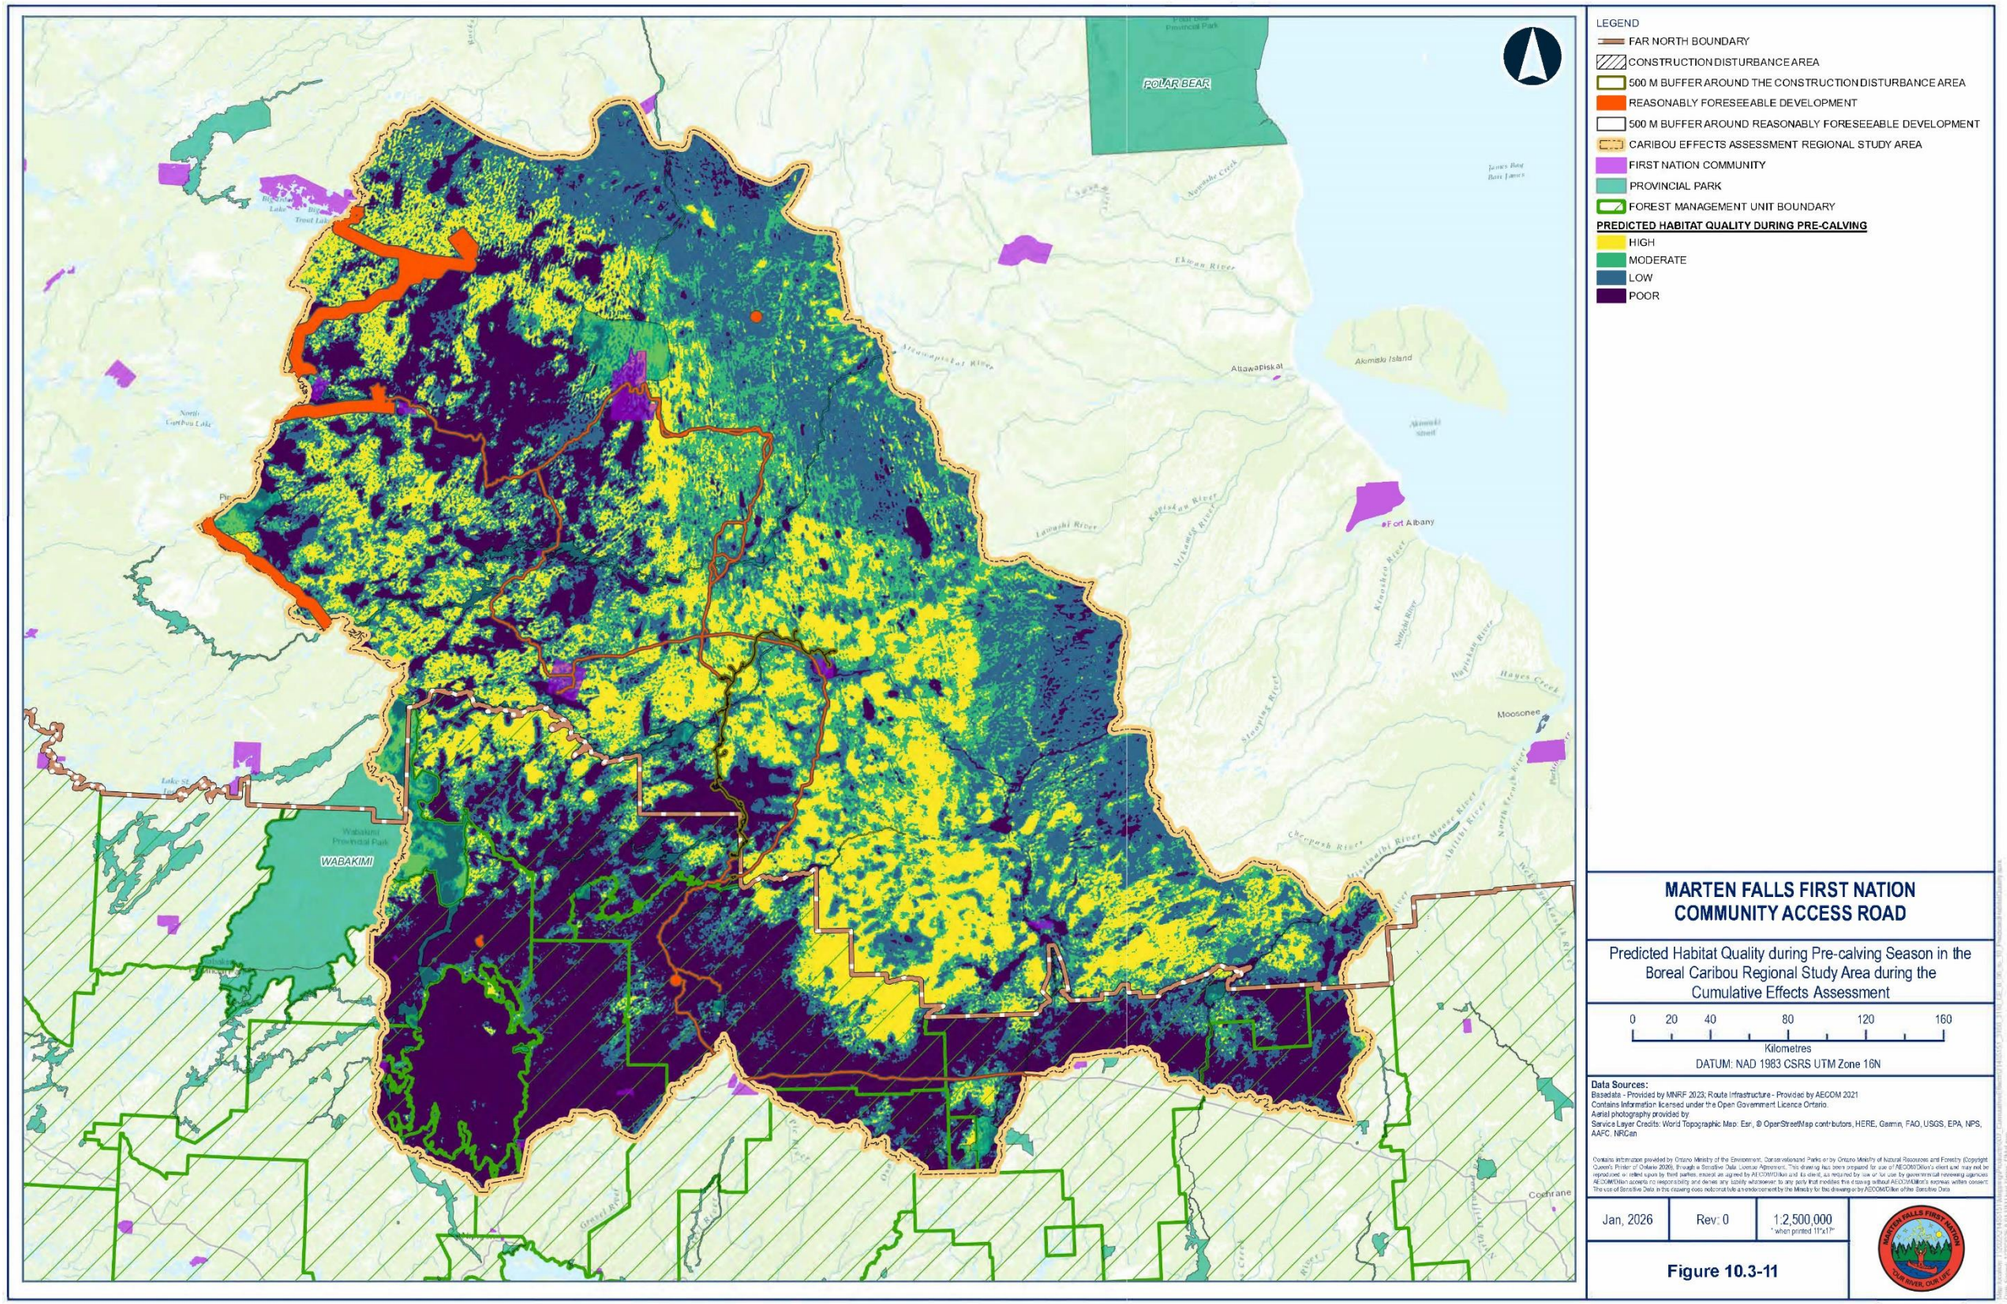

Figure 10.3-11: Predicted Habitat Quality during Pre-calving Season in the Boreal Caribou Regional Study Area During the Cumulative Effects Assessment

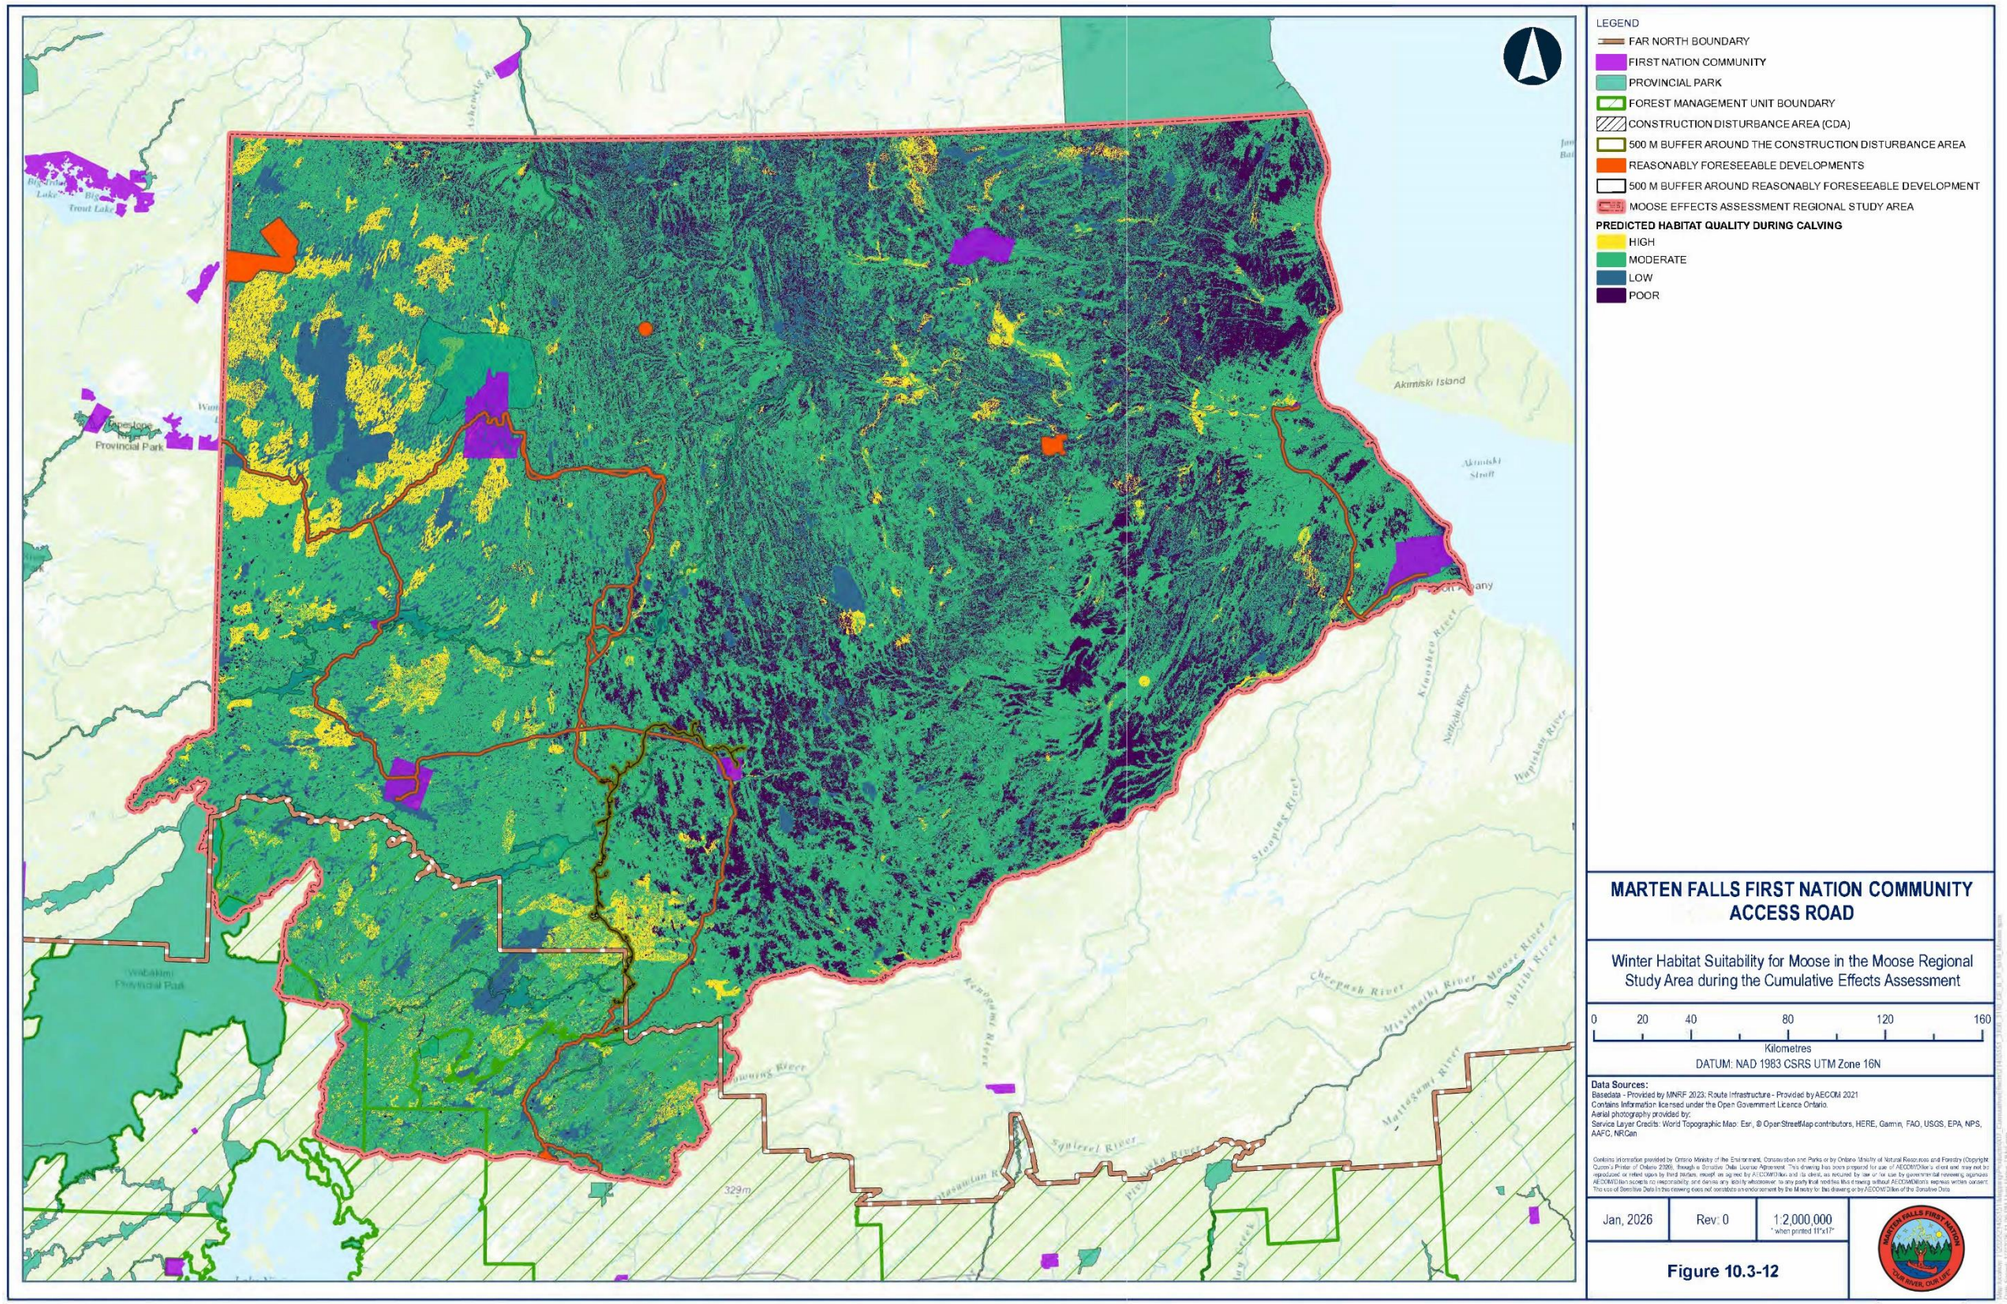
Effects from habitat loss and alteration on the ability of the boreal caribou populations in the boreal caribou effects assessment Regional Study Area to remain self-sustaining and ecologically functional are anticipated to be negative and of low magnitude for the Missisa, Ozhiski and Pagwachuan ranges. The Nipigon range was assessed as not self-sustaining under existing conditions, and thus any additional habitat loss is considered to be of moderate magnitude.



Overall, the cumulative effects from the implementation of the Community Access Road and past, present, and reasonably foreseeable activities may affect boreal caribou habitat connectivity. However, a large amount of suitable habitat will remain undisturbed and connected in the boreal caribou effects assessment Regional Study Area, relative to existing conditions. Given animal movement and habitat use are dynamic over time, the magnitude of effect will likely vary during the lifespan of the projects.

10.3.5.2 Moose

The Community Access Road, past, present, and reasonably foreseeable developments are predicted to have the following cumulative effects on moose:

- Removal of an estimated 64,872 hectares of high, moderate, and low suitability winter moose habitat (combined). This represents a cumulative direct loss of 1.0 percent and 0.4 percent of high and moderate suitability habitat. Winter habitat suitability for moose in the Cumulative Effects Assessment is shown on **Figure 10.3-12**.
- Sensory disturbance (noise, smells, light spill, human presence) are expected to reduce habitat quality and elicit avoidance by moose in proximity of each projects' disturbance footprint. An additional 128,045.7 hectares of high and moderate suitability habitat is predicted to be indirectly disturbed by sensory disturbance.
- Linear disturbances may result in physical and perceived barriers to movement, particularly in the southern and northwestern portion of the moose effects assessment Regional Study Area.
- Introduction of linear corridors expected to be used by predators and the public to facilitate access to areas that are less accessible in the existing environment.
- Introduction of roads (all-season roads, temporary and permanent access roads), are expected to increase the risk of moose collisions with vehicles and equipment.

Figure 10.3-12: Winter Habitat Suitability for Moose in the Moose Regional Study Area during the Cumulative Effects Assessment

- Dust deposition is predicted to degrade vegetation in areas immediately adjacent to the Community Access Road and past, present, and reasonably foreseeable developments.
- Potential for alterations to drainage patterns, and increase or decrease of groundwater levels, thereby affecting moose habitat availability and distribution.

Additionally, climate change may contribute cumulatively to changes in the quality, quantity, and distribution of moose habitat, and moose survival and reproduction. However, the magnitude of change to moose habitat availability, distribution, and survival and reproduction from climate change on moose habitat and populations is uncertain.

Cumulative effects to moose will begin during construction and continue through the operations of the Community Access Road. Effects on moose from the all-season roads and road upgrades will be irreversible as these activities will remain in operation indefinitely. Effects from other developments including transmission lines and mines may be reversible over the long-term if temporary features are reclaimed or left to naturally revegetate.

Overall, the regional moose populations are expected to remain self-sustaining and ecologically effective in the Cumulative Effects Assessment (in other words, there is no predicted change in the assessment endpoints). The anticipated changes to moose habitat availability, distribution, and survival and reproduction from the Community Access Road and past, present, and reasonably foreseeable activities, and climate change are expected to remain within the resilience and adaptability limits of the regional populations.

10.3.5.3 Mitigation Measures

10.3.5.3.1 Boreal Caribou

It is anticipated that the mitigation measures that will be implemented to minimize effects on boreal caribou during the construction, operation, and closure (where applicable) of past, present, and reasonably foreseeable activities will be similar to those implemented for the Community Access Road. Refer to **Section 9.4.5** for a complete description of the proposed mitigation measures for ungulates.

These projects will also be required to meet permitting requirements from the Ministry of Natural Resources and Ministry of Environment, Conservation and Parks, including considerations related to restricted activity timing windows. Indigenous Environmental Monitors would also be expected to be onsite during construction.

Similar to the Community Access Road, it is expected that reasonably foreseeable activities that overlap with the boreal caribou effects assessment Regional Study Area will be required to implement an Environmental Protection Plan and, in some cases, a Biodiversity Offsetti Plan. The offset plan is expected to provide a net increase in functional habitat for boreal caribou. For the boreal caribou Cumulative Effects Assessment, offsetting programs have not been included in the characterization of effects.

It is expected that the effectiveness of mitigation measures for these activities will be evaluated throughout construction, operation, and closure, where applicable, and will be modified or enhanced as necessary through adaptive management.

10.3.5.3.2 Moose

It is expected that the mitigation measures that will be implemented to minimize effects from habitat loss on moose habitat availability, distribution, survival and reproduction from the implementation of past, present, and reasonably foreseeable activities will be similar to those implemented for the Community Access Road. Refer to **Section 9.4.5** for a complete description of the proposed mitigation measures for ungulates.

It is expected that the effectiveness of mitigation measures for these activities will be evaluated throughout construction, operations and closure (where applicable), and will be modified or enhanced as necessary through adaptive management.

10.3.5.4 Determination of Significance

10.3.5.4.1 Boreal Caribou

A conservative approach was applied to the determination of significance on boreal caribou because this assessment was primarily informed by 2 years of recent collar data for boreal caribou; individuals that were targeted for collaring were those that interacted with the ungulate effects assessment Local Study Area in winter 2021. Two years of data is relatively short when compared to the longevity of boreal caribou and acquiring confident knowledge of movement patterns.

Based on the weight of evidence, uncertainty in effects predictions and application of the precautionary approach, changes in habitat availability and distribution and survival and reproduction as a result of the Community Access Road and past, present, and reasonably foreseeable developments could approach or extend beyond the resilience capabilities of one or more boreal caribou population(s) overlapping the boreal caribou effects assessment Regional Study Area. As a result, the combined residual cumulative effects from the Community Access Road and past, present, and reasonably foreseeable developments on boreal caribou and boreal caribou habitat are determined

to have a **significant** influence on self-sustaining and ecologically effective boreal caribou populations in the boreal caribou effects assessment Regional Study Area.

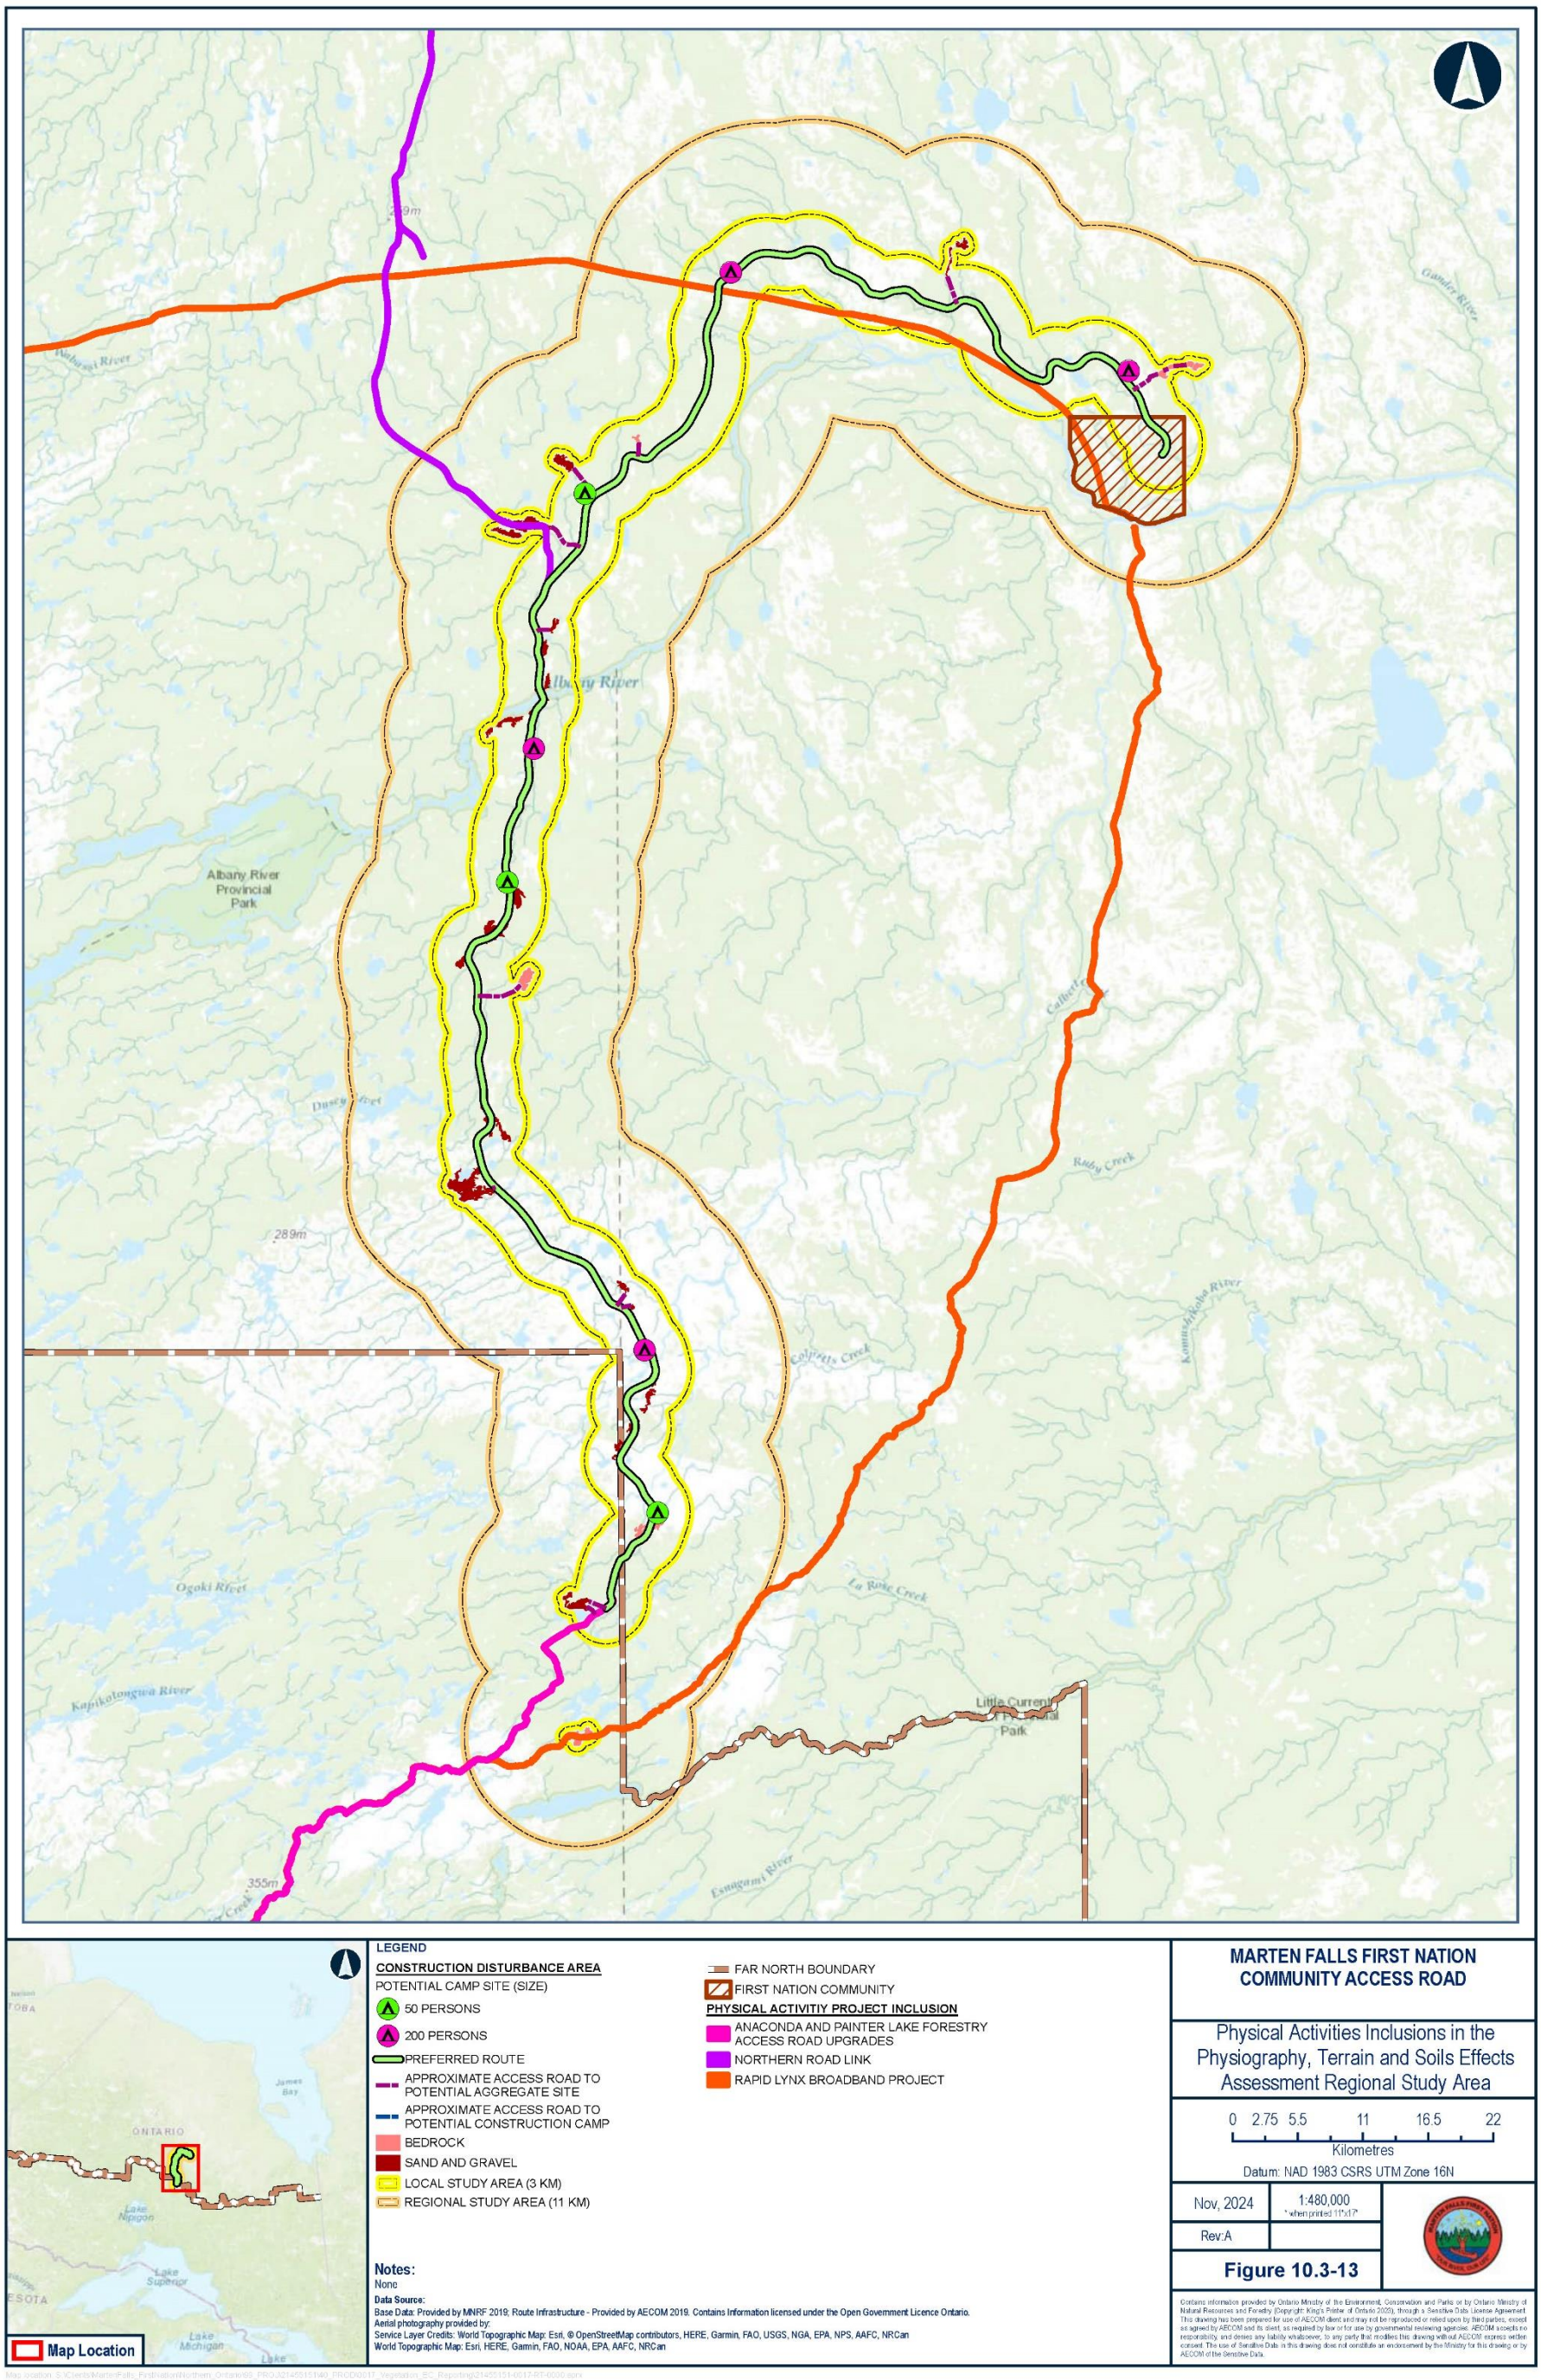
10.3.5.4.2 Moose

Given the uncertainty in the potential increases in non-Indigenous and Indigenous moose harvest and the limited data on current Indigenous harvest levels, it was precautionarily assumed that the effects of increases in public access from past, present, and reasonably foreseeable activities could reach unsustainable levels and lead to decreased resilience and maintenance of the self-sustaining and ecologically effective regional moose population. As such, cumulative residual effects on moose from increase in public access are precautionarily considered **significant.**

However, all other effects pathways from the Community Access Road, and past, present, and reasonably foreseeable activities are not predicted to significantly affect the ability of the regional moose population to remain self-sustaining and ecologically effective (there is no predicted change in the assessment endpoints). As such, all other effects pathways are considered **not significant.**

10.3.6 Physiography, Terrain, and Soils

Three valued components with residual effects were carried forward to the physiography, terrain, and soils Cumulative Effects Assessment:



- Changes to terrain quantity and distribution from construction activities;
- Changes to terrain quantity and distribution (esker landforms) from construction activities; and
- Changes to quantity and distribution of soils from construction activities.

The locations of the projects considered for the Cumulative Effects Assessment in relation to the physiography, terrain, and soils Regional Study Area are shown on **Figure 10.3-13**.

10.3.6.1 Changes to Terrain Quantity and Distribution from Construction Activities

Project activities such as clearing, earth moving, excavation at pits and / or blasting at quarry sites, and other road construction activities from the construction of the Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades have the potential for cumulative effects on the quantity and distribution of terrain through the physical alteration and removal of terrain. Cumulative effects may begin during construction and continue through operation.

Figure 10.3-13: Physical Activities Inclusions in the Physiography, Terrain and Soils Effects Assessment Regional Study Area

It is expected that the Northern Road Link and the Anaconda and Painter Lake Forestry Access Road upgrades would have similar road design as the Community Access Road, and minimize the project footprint, where possible. As a result, the effects from each project on the quantity and distribution of terrain units from construction activities are expected to be minimized and have limited potential for cumulative effects on the quantity and distribution of terrain units.

10.3.6.2 Changes to Terrain Quantity and Distribution (Esker Landforms) from Construction Activities

Project activities such as sand and gravel pit creation and aggregate extraction from the construction of the Northern Road Link and the Anaconda and Painter Lake Forestry Access Road upgrades, along with the Community Access Road, have the potential to cause physical alteration or removal of esker landforms.

The Community Access Road is anticipated to impact 31 percent of the eskers in the Regional Study Area, and the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades are anticipated to cause cumulative changes to the physical alteration of eskers if they are used as sources of road building materials (sand and gravel resources). Cumulative effects may begin during construction and continue through operation. It is anticipated that the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades would minimize or avoid the development of eskers as borrow pits by identifying alternative sources of aggregate such as bedrock quarries or sand and gravel glaciofluvial deposits that are not esker landforms. As a result, the effects from each project would be expected to be minimized and have limited potential for cumulative effects on the quantity and distribution of esker landforms.

10.3.6.3 Changes to Quantity and Distribution of Soils from Construction Activities

Project activities such as clearing, earth moving, excavation at pits and / or blasting at quarry sites and other road construction activities from the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades, along with the Community Access Road, have the potential for cumulative effects on the quantity and distribution of soil. Cumulative effects may begin during construction and continue through operation.

Although the development of the Community Access Road, Northern Road Link, and Anaconda and Painter Lake Forestry Access Road upgrades will permanently disturb landscape within the Regional Study Area, only 1.1 percent of the Regional Study Area is anticipated to be cumulatively disturbed. Therefore, the cumulative effect on changes to terrain and soil quantity and distribution is considered to be negligible.

10.3.6.4 Mitigation Measures

It is anticipated that mitigation measures will be, or have been, implemented to limit changes to physiography, terrain, and soils during the construction and operation of the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades and that these mitigation measures will be similar to those implemented for the Community Access Road. Refer to **Section 9.4.6** for a complete description of the proposed mitigation measures for physiography, terrain, and soils.

10.3.6.5 Determination of Significance

Significance was determined only for disciplines where it was required to meet federal or provincial requirements. For the purposes of this Cumulative Effects Assessment, significance of the effects for physiography, terrain, and soils was not determined.

10.3.7 Summary of Cumulative Effects

Table 10.3-3 summarizes the cumulative effects for the land disciplines.

Table 10.3-3: Summary of Predicted Cumulative Effects for Land Disciplines

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
• **Vegetation**	• Upland Ecosystems	• Changes to ecosystem availability, distribution, composition and function as a result of direct vegetation loss	• Negative	• Low magnitude	• Regional (reasonably foreseeable developments) • Beyond regional (due to climate change)	• Long-term and irreversible (for permanent impacts) • Medium-term and Reversible (for temporary impacts where vegetation communities can and will be restored)	• Continuous	• Irreversible (for permanent impacts) • Reversible (for temporary impacts where vegetation communities can and will be restored)	• Certain (reasonably foreseeable developments) • Probable (climate change)	• Not significant	• Moderate
• **Vegetation**	• Wetland Ecosystems	• Changes to ecosystem availability, distribution, composition and function as a result of direct vegetation loss	• Negative	• Low magnitude	• Regional (reasonably foreseeable developments) • Beyond regional (due to climate change)	• Long-term (for permanent impacts) • Medium-term (for temporary impacts where vegetation communities can and will be restored)	• Continuous	• Irreversible (for permanent impacts) • Reversible (for temporary impacts where vegetation communities can and will be restored)	• Certain (reasonably foreseeable developments) • Probable (climate change)	• Significant	• Moderate
• **Vegetation**	• Riparian Ecosystems	• Changes to ecosystem availability, distribution, composition and function as a result of direct vegetation loss	• Negative	• Low magnitude	• Regional (reasonably foreseeable developments) • Beyond regional (due to climate change)	• Long-term (for permanent impacts) • Medium-term (for temporary impacts where vegetation communities can and will be restored)	• Continuous	• Irreversible (for permanent impacts) • Reversible (for temporary impacts where vegetation communities can and will be restored)	• Certain (reasonably foreseeable developments) • Probable (climate change)	• Not significant	• Moderate
• **Vegetation**	• Designated Areas	• Changes to ecosystem availability, distribution, composition and function as a result of direct vegetation loss	• Negative	• Low magnitude	• Regional (reasonably foreseeable developments) • Beyond regional (due to climate change)	• Long-term (for permanent impacts) • Medium-term (for temporary impacts where vegetation communities can and will be restored)	• Continuous	• Irreversible (for permanent impacts) • Reversible (for temporary impacts where vegetation communities can and will be restored)	• Certain (reasonably foreseeable developments) • Probable (climate change)	• Not significant	• Low (reasonably foreseeable developments) • Moderate (climate change)
• **Vegetation**	• Traditional Use Plants	• Changes to population availability, distribution, composition and function as a result of direct vegetation loss	• Negative	• Low magnitude	• Regional (reasonably foreseeable developments) • Beyond regional (due to climate change)	• Long-term (for permanent impacts) • Medium-term (for temporary impacts where vegetation communities can and will be restored)	• Continuous	• Irreversible (for permanent impacts) • Reversible (for temporary impacts where vegetation communities can and will be restored)	• Certain (reasonably foreseeable developments) • Probable (climate change)	• Not significant	• Moderate
• **Vegetation**	• Species at Risk and Species of Conservation Concern	• Changes to population availability, distribution, composition and function as a result of direct vegetation loss	• Negative	• Low magnitude	• Regional (reasonably foreseeable developments) • Beyond regional (due to climate change)	• Long-term (for permanent impacts) • Medium-term (for temporary impacts where vegetation communities can and will be restored)	• Continuous	• Irreversible (for permanent impacts) • Reversible (for temporary impacts where vegetation communities can and will be restored)	• Certain (reasonably foreseeable developments) • Probable (climate change)	• Not significant	• Moderate

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
Vegetation	Vegetation (all vegetation valued components except Wetland Ecosystems)	Changes to ecosystem or population availability, distribution, composition and function as a result of changes in groundwater during the construction and operations	Negative	Moderate magnitude	Regional	Long-term	Continuous	Irreversible	Probable	Not significant	Moderate
Vegetation	Wetland Ecosystems	Changes to Wetland Ecosystem availability, distribution, composition and function as a result of changes in groundwater	Negative	Medium	Regional	Long-term	Continuous	Irreversible	Probable	Significant	High
Vegetation	Vegetation	Changes to ecosystem or population availability, distribution, composition and function as a result of fragmentation and edge effects during construction	Negative	Negligible	Beyond regional (due to climate change)	Medium-term	Frequent	Irreversible	Probable	Not significant	Moderate
Vegetation	Vegetation	Changes to ecosystem or population availability, distribution, composition and function as a result of fugitive dust emissions during construction and operations	Negative	Negligible	Regional	Long-term	Continuous	Irreversible	Certain	Not significant	Moderate
Wildlife	All wildlife	Fugitive Dust Emissions	Negative	Negligible	Regional	Long-term	Continuous	Irreversible	Probable	Not Significant	Moderate
Wildlife	All wildlife	Changes to Groundwater	Negative	Negligible	Regional	Long-term	Continuous	Irreversible	Probable	Not Significant	Moderate
Wildlife	Bats	Habitat Loss and Alteration	Negative	Low magnitude	Regional	Permanent	Continuous	Irreversible	Certain	Not significant	Moderate
Wildlife	Bats	Sensory Disturbance	Negative	Negligible	Regional	Medium-term (construction) Permanent (operations)	Continuous	Reversible (construction) Irreversible (operations)	Probable	Not significant	Moderate

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
• **Ungulates**	• Boreal Caribou	• Habitat Loss and Alteration	• Negative	• Low magnitude in Missisa, Ozhiski and Pagwachuan ranges • Moderate magnitude in Nipigon range	• Regional for habitat availability and survival and reproduction. • Beyond regional for habitat distribution (boreal caribou movement and connectivity) and climate change.	• Long-term	• Continuous	• Irreversible	• Certain (reasonably foreseeable developments) • Probable (climate change)	• Not significant	• Low for habitat availability and survival and reproduction. • High for habitat distribution (boreal caribou movement and connectivity) and climate change.
• **Ungulates**	• Boreal Caribou	• Sensory Disturbance	• Negative	• Low magnitude	• Regional	• Long-term	• Continuous (construction of all reasonably foreseeable developments, and operations of the all-season roads, upgraded roads, Eagle's Nest Project Mine) • Infrequent (operations of the Rapid Lynx Broadband project, Wataynikaniyap Powerline)	• Irreversible (although sensory disturbance from some reasonably foreseeable developments may be reversible after closure)	• Certain during construction of each project; • Probable during operation of each project.	• Not significant	• Moderate
• **Ungulates**	• Boreal Caribou	• Linear barriers	• Negative	• High magnitude in the Missisa range • Moderate magnitude in the Ozhiski range • Low magnitude in the Nipigon range • Negligible magnitude in the Pagwachuan range	• Regional for habitat availability • Beyond regional for habitat distribution and survival and reproduction (habitat and population connectivity and animal movement)	• Long-term	• Continuous	• Irreversible (for the all-season roads and permanent access roads) • Reversible (for access roads and utility corridors that will be revegetated)	• Probable	• Not significant	• High

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
• **Ungulates**	• Boreal Caribou	• Increased predator access	• Negative	• Negligible magnitude	• Regional	• Long-term (for the all-season roads, permanent access roads, and utility corridors) • Medium-term (for access roads that will be revegetated)	• Continuous	• Irreversible	• Probable	• Not significant	• Moderate
• **Ungulates**	• Boreal Caribou	• Increase in public access	• Negative	• Low magnitude	• Regional	• Long-term	• Continuous	• Irreversible	• Possible	• Not significant	• High
• **Ungulates**	• Boreal Caribou	• Collisions with vehicles and equipment	• Negative	• Moderate magnitude	• Regional	• Long-term	• Continuous	• Irreversible	• Possible (during construction of reasonably foreseeable developments) • Probable (during operations of reasonably foreseeable developments)	• Not significant	• Low (Construction) • High (Operations)
• **Ungulates**	• Boreal Caribou	• Fugitive dust emissions	• Negative	• Negligible magnitude	• Regional	• Long-term	• Continuous	• Irreversible	• Certain	• Not significant	• Low
• **Ungulates**	• Boreal Caribou	• Changes to Groundwater	• Negative	• Negligible magnitude	• Regional	• Long-term	• Continuous	• Irreversible	• Probable	• Not significant	• Moderate
• **Ungulates**	• Moose	• Habitat loss and alteration	• Negative	• Low magnitude	• Regional for changes associated with the Community Access Road and past, present, and reasonably foreseeable developments • Beyond Regional for changes associated with climate change	• Long-term	• Continuous	• Irreversible	• Certain (habitat availability) • Probable (habitat distribution, survival and reproduction) • Probable for changes associated with climate change	• Not significant	• Low (habitat availability, survival and reproduction) • Moderate (habitat distribution) • High for changes associated with climate change
• **Ungulates**	• Moose	• Sensory disturbance	• Negative	• Low magnitude	• Regional (localized around the Community Access Road and past, present, and reasonably foreseeable activities)	• Long-term	• Continuous •	• Irreversible / Reversible if moose habituate to vehicle traffic throughout the lifetime of these activities	• Certain (Habitat availability) • Probable (Habitat distribution, survival and reproduction)	• Not significant	• Low (habitat availability and survival and reproduction) • Moderate (habitat distribution)

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
• **Ungulates**	• Moose	• Linear barriers	• Negative	• Low magnitude	• Regional for habitat availability and survival and reproduction (localized within and around the Community Access Road and reasonably foreseeable activities that will introduce linear disturbance) • Beyond regional for habitat distribution (habitat connectivity and movement)	• Long-term	• Continuous	• Irreversible for permanent linear corridors and disturbances • Reversible for temporary linear features that will be decommissioned and / or reclaimed or left to revegetate (decommissioned access roads, rights-of-way)	• Probable	• Not significant	• Moderate
• **Ungulates**	• Moose	• Increased predator access	• Negative	• Low magnitude	• Regional (localized within and around the Community Access Road and reasonably foreseeable activities that will introduce linear disturbance)	• Long-term	• Continuous	• Irreversible for activities with permanent linear corridors (all-season roads, permanent access roads, utility projects) • Reversible for temporary linear features that will be reclaimed or left to revegetate naturally (decommissioned access roads)	• Probable	• Not significant	• Moderate
• **Ungulates**	• Moose	• Increase in public access	• Negative	• High magnitude	• Regional (localized around the Community Access Road and reasonably foreseeable activities that will introduce linear disturbance, but effects could extend regionally)	• Long-term	• Continuous	• Irreversible	• Probable	• Significant	• High
• **Ungulates**	• Moose	• Collisions with vehicles and equipment	• Negative	• Negligible magnitude during construction • Moderate magnitude during operations	• Regional (localized on the project footprints of the Community Access Road, past, present, and reasonably foreseeable activities)	• Long-term	• Continuous	• Irreversible	• Possible (construction and closure (if applicable) of the Community Access Road and past, present, and reasonably foreseeable developments) • Probable (operations of the Community Access Road and other projects that have operational roads)	• Not significant	• Low (construction and closure of the Community Access Road and all past, present, and reasonably foreseeable developments) • High (operations of the Community Access Road and other projects that have operational roads)

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
• **Ungulates**	• Moose	• Fugitive dust emissions	• Negative	• Negligible magnitude	• Regional (localized around the project footprints of the Community Access Road, past, present, and reasonably foreseeable activities)	• Long-term	• Continuous	• Irreversible	• Certain	• Not significant	• Low
• **Ungulates**	• Moose	• Changes to groundwater	• Negative	• Negligible magnitude	• Regional	• Long-term	• Continuous	• Irreversible	• Probable	• Not significant	• Moderate
• **Physiography, Terrain and Soils**	• Changes to Terrain Quality and Distribution	• Changes to Terrain Quality and Distribution from Construction Activities	• Negative	• Negligible	• Regional Study Area	• Long-term	• Infrequent	• Irreversible	• Certain	• Not applicable	• Moderate
• **Physiography, Terrain and Soils**	• Changes to Esker Landforms	• Changes to Esker Landforms from Construction Activities	• Negative	• Medium	• Regional Study Area	• Long-term	• Infrequent	• Irreversible	• Possible	• Not applicable	• Moderate
• **Physiography, Terrain and Soils**	• Changes to Quantity and Distribution of Soils	• Changes to Quantity and Distribution of Soils from Construction Activities	• Negative	• Negligible	• Regional Study Area	• Long-term	• Infrequent	• Irreversible	• Certain	• Not applicable	• Moderate

10.4 People

10.4.1 Scoping

Where residual effects identified in **Section 9** were negligible magnitude, unlikely or possible to occur, or positive in direction, the effect was not carried forward into the Cumulative Effects Assessment. The valued components with residual effects that have been carried forward for the Cumulative Effects Assessment for people disciplines are described in **Table 10.4-1.**

To determine the spatial boundaries of potential cumulative effects, the projects listed in **Table 10.4-2** were considered for the Cumulative Effects Assessment. The remainder of the projects on the Project Inclusions List were determined to have no spatial or temporal overlap with the people disciplines study areas; therefore, they were not considered as part of the Cumulative Effects Assessment.

Table 10.4-1: Valued Components Carried Forward and Corresponding Spatial and Temporal Boundary for People Disciplines

Discipline	Valued Component	Spatial Boundary	Temporal Boundary
• **Aboriginal and Treaty Rights and Interests**	• Indigenous Current Use of Land and Resources for Traditional Purposes	• Aboriginal and / or Treaty Rights and Interests Boreal Caribou Regional Study Area.	• Construction • Operations
• **Aboriginal and Treaty Rights and Interests**	• Cultural Continuity and Well-being	• Aboriginal and / or Treaty Rights and Interests Boreal Caribou Regional Study Area.	• Construction • Operations
• **Acoustic and Vibration**	• Noise	• Construction Disturbance Area plus a 4-kilometre buffer.	• Construction • Operation
• **Acoustic and Vibration**	• Vibration	• Construction Disturbance Area plus a 4-kilometre buffer.	• Construction • Operation
• **Archaeology**	• Not Applicable	• Not Applicable	• Not Applicable
• **Atmospheric**	• Air Quality	• Construction Disturbance Area plus a 12.3-kilometre buffer.	• Congruent periods of emissions between the Community Access Road construction or operation and other projects within the spatial boundary (emissions occurring at the same time from multiple projects)
• **Greenhouse Gas**	• Not Applicable	• Not Applicable	• Not Applicable
• **Cultural Heritage**	• Not Applicable	• Not Applicable	• Not Applicable
• **Community Well-Being**	• Community Access to Infrastructure and Services	• Local Study Area (Marten Falls First Nation; Aroland First Nation).	• Construction
• **Community Well-Being**	• Cultural Preservation and Change	• Local Study Area (Marten Falls First Nation; Aroland First Nation; Indigenous Communities with Overlapping Interests).	• Construction and operation
• **Community Well-Being**	• Community and Public Health	• Local Study Area (Marten Falls First Nation; Aroland First Nation; Indigenous Communities with Overlapping Interests).	• Construction and operations
• **Community Well-Being**	• Traditional Foods	• Local Study Area (Marten Falls First Nation; Aroland First Nation; Indigenous Communities with Overlapping Interests).	• Construction and operations
• **Community Well-Being**	• Access to Clean Water	• Local Study Area (Marten Falls First Nation; Aroland First Nation; Indigenous Communities with Overlapping Interests).	• Construction and operations
• **Community Well-Being**	• Public Safety	• Local Study Area (Marten Falls First Nation; Aroland First Nation; Indigenous Communities with Overlapping Interests).	• Construction and operation.
• **Community Well-Being**	• Biophysical Determinants of Health (Air)	• Local Study Area (Marten Falls First Nation; Aroland First Nation; Indigenous Communities with Overlapping Interests).	• Construction and operation.
• **Community Well-Being**	• Biophysical Determinants of Health (surface water, sediment, soil and groundwater)	• Local Study Area (Marten Falls First Nation; Aroland First Nation; Indigenous Communities with Overlapping Interests).	• Construction and operation.
• **Land and Resource Use**	• Trapping	• 100-metre-wide Community Access Road right-of-way, temporary construction access roads, work areas, worker camps, and pits, quarries, and associated access roads.	• Construction • Operation
• **Visual**	• Cultural Heritage Resources and Indigenous Experience and Sense of Place	• Within 8 kilometres (total of 16 kilometres) of the centerline of the route alternatives.	• Construction • Operation
• **Visual**	• Recreation and Tourism	• Within 8 kilometres (total of 16 kilometres) of the centerline of the route alternatives.	• Construction • Operation
• **Visual**	• Parks and Protected Areas	• Within 8 kilometres (total of 16 kilometres) of the centerline of the route alternatives.	• Construction • Operation
• **Visual**	• Permanent Settlements	• Within 8 kilometres (total of 16 kilometres) of the centerline of the route alternatives.	• Construction • Operation

Table 10.4-2: Project and Physical Activities Carried Forward for Land Disciplines

Discipline(s)	Project	Project Description	Project / Activity Reasonably Foreseeable (Y/ N)	Valued Components Temporal Overlap with Project (Y / N)	Valued Components Spatial Overlap with Project (Y / N)
• **Aboriginal and Treaty Rights and Interests** • **Acoustic and Vibration** • **Atmospheric** • **Land and Resource Use** • **Community Well-Being** • **Visual**	• Northern Road Link	• Marten Falls First Nation and Webequie First Nation are proposing to build, operate and maintain an all-season multi-use road and associated infrastructure between the Community Access Road that has been proposed by Marten Falls First Nation and the supply road that has been proposed by Webequie First Nation. • Terms of Reference for the preparation of an Environmental Assessment were approved March 3, 2023.	• Yes	• Yes	• Local Study Area - Yes • Regional Study Area - Yes
• **Aboriginal and Treaty Rights and Interests** • **Acoustic and Vibration** • **Atmospheric** • **Land and Resource Use** • **Community Well-Being** • **Visual**	• Anaconda and Painter Lake Forestry Access Road Upgrades	• Upgrades to existing road will be required for heavy vehicles accessing the Community Access Road route during construction and operations. • Currently discussions on proponency and scope of work are underway. • Potential scope of work is expected to include roadway widening, culvert and bridge replacements / rehabilitations to accommodate higher weight vehicles, and road base improvements. • This project will be completed prior to the start of the construction of the Community Access Road and therefore the upgrade to these roads is not expected to overlap with the construction of the Community Access Road.	• Yes	• Yes	• Local Study Area - Yes • Regional Study Area - Yes
• **Aboriginal and Treaty Rights and Interests** • **Atmospheric** • **Land and Resource Use**	• Ogoki Forest Management Plans	• Forest Management Plans for the Ogoki Forest. • Includes Ogoki-Armstrong Primary Roads as these roads are being used for forest management. • Includes plans for future harvest. • Ogoki Forest is approximately 10,900 square kilometres in size and includes approximately 9,798 square kilometres of forested area. • Majority of the forest is traditional territory and is subject to forest management planning and forest management operations.	• Yes	• Yes	• Local Study Area - Yes • Regional Study Area - Yes
• **Aboriginal and Treaty Rights and Interests** • **Atmospheric** • **Community Well-Being** • **Visual**	• Rapid Lynx Broadband	• Approximately 810 kilometres of fibre-optic cables, providing reliable high-speed internet service to five Matawa First Nation communities: Eabametoong, Marten Falls, Neskantaga, Nibinamik, and Webequie with an interconnection at Aroland.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests** • **Community Well-Being**	• Esnagami Road Bypass Upgrade	• Upgrades to existing road to use as a bypass route around Aroland First Nation settlement area by heavy vehicles accessing the Community Access Road route towards the Ring of Fire. • Currently discussions on proponency and scope of work are underway. • Potential scope of work is expected to include roadway widening, bridge and culvert rehabilitation / replacement, and road base improvements.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests** • **Community Well-Being**	• Transload Facility	• Rail transload facility to Aroland First Nation.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests** • **Community Well-Being**	• Webequie Supply Road	• New Community Access Road approximately 107 kilometres in length from Webequie First Nation to the mineral deposit near McFaulds Lake for mineral exploration and future mining development activities. • 17 kilometres of the corridor is within Webequie First Nation Reserve Lands.	• Yes	• Yes	• Yes
• **Acoustic and Vibration** • **Community Well-Being**	• Winter Access Road Realignment Project	• Funding to remote northern communities for projects involving installation of water crossing infrastructure, such as pre-engineered bridges and culverts, and repairs to existing structures. • Funding for approximately 3,200 kilometres of winter access roads in Northern Ontario.	• Yes	• Yes	• Yes

Discipline(s)	Project	Project Description	Project / Activity Reasonably Foreseeable (Y/ N)	Valued Components Temporal Overlap with Project (Y / N)	Valued Components Spatial Overlap with Project (Y / N)
• **Community Well-Being**	• Equinox Gold Corp.'s Greenstone Gold Mine	• Construction, operation, decommissioning and abandonment of an open-pit gold mine and onsite metal mill located near Geraldton, Ontario. • Production estimated at 30,000 tonnes per day. • Amended Decision Statement issued February 10, 2021. • First gold pour is anticipated in early 2024.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Ogoki and Long Lac Diversions	• Divert water from a portion of the Hudson Bay watershed into the Lake Superior basin. • Long Lac diversion inflows approximately 39 cubic metres per second into the Great Lakes Basin. • Ogoki diversion inflows approximately 113 cubic metres per second into the Great Lakes Basin.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Gull Bay Roads Rehabilitation	• Rehabilitate approximately 10 kilometres of roads in the Gull Bay First Nation in Ontario. • Relocation of the community's entrance and exit to Highway 527; rebuilding the road base and widening certain sections; grading and brush clearing to improve sightlines; addressing drainage issues through ditching and the replacement of an estimated 43 culverts; installing street and traffic control signs (street, stop, yield, and speed signs plus pedestrian warnings); and resurfacing Main Street and Streets A through M with Granular A along with calcium chloride for dust suppression. • Infrastructure Ontario issued its Notice of Determination on July 15, 2021, and determined that the project is not likely to cause significant adverse environmental effects.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Wataynikaneyap • Powerline	• Construction of a 230 kilovolts line between Ignace and Dryden, to Pickle Lake (Phase 1). • Construction of electricity transmission lines to Pickle Lake and north of Red Lake, connecting 17 remote northern Ontario communities to grid power (Phase 2). • Operation of both project phases overlap with the construction and operations of the Community Access Road.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Kasabonika Lake First Nation Band Representative Facility	• The Kasabonika Lake First Nation Band Representative Facility project involves the construction of a new single-story Child and Family Service building and housing facilities for staff in the community of Kasabonika Lake. • Includes tree clearing, lot development, parking lot and laneway construction, connection to community's water and wastewater infrastructure and building construction.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Kashechewan First Nation - 20 Lot Development	• Development of 20 lots with future use to build family homes for the community. Each lot is roughly 929 metres in size. • The project will include site preparation activities including clearing, grubbing, granular placement, and servicing of lots with municipal utilities and services. • The Notice of Determination was issued on November 17, 2023, and determined that the project is not likely to cause significant adverse environmental effects.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Attawapiskat First Nation - Airport Heights Residential Subdivision	• Lot servicing project, for a maximum of 28 serviced residential lots in the proposed Airport Heights Residential Subdivision.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Neskantaga First Nation Community Recreation Centre	• Renovation of the existing community recreation centre and arena, to include an additional 2,400 square feet in size and will include washrooms.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Rehabilitation of Nibinamik Lagoon Sewage Treatment Lagoon and Collection Systems	• Repair and replacement of components of a sewage lagoon and the purchase of a septic truck in Nibinamik First Nation. • Includes re-excavating and repairing 30 manholes and covers, flushing outflow lines, removing and replacing two pressure relief valves, repairing damaged section of the lagoon, and buying a septic truck.	• Yes	• Yes	• Yes
• **Aboriginal and Treaty Rights and Interests**	• Accelerated High-Speed Internet Program	• Providing access to reliable, high-speed internet to unserved and underserved communities across the province by the end of 2025.	• Yes	• Yes	• Yes

10.4.2 Aboriginal and / or Treaty Right and Interests

As described in **Section 8.3.4**, Indigenous communities have received a detailed report specific to their existing conditions and impacts. The impact assessment included information on potential project interactions in relation to Aboriginal and / or Treaty Rights and Interests. Communities were given the opportunity to review and provide feedback on their draft reports.

The Aboriginal and / or Treaty Rights and Interests cumulative impacts assessment carries forward indicators identified in the residual impacts and discusses potential cumulative impacts on each Indigenous community's Aboriginal and / or Treaty rights and interests, identifies mitigation measures, and characterizes the predicted adverse residual cumulative impacts.

The following describes the cumulative impact assessment for the Preferred Route across both temporal phases of the Community Access Road. It does not include the results of the cumulative impact assessment, which will be shared with each Indigenous community in their community-specific Aboriginal and / or Treaty Rights and Interests: Impact Assessment reports.

To support a comprehensive regulatory review, these community-specific reports will be shared with the Regulator. They form part of the evidence base for determining the assessment outcome.

Due to confidentiality and / or the sensitive nature of the information, detailed community reports are not being shared publicly.

10.4.2.1 Indigenous Current Use of Lands and Resources for Traditional Purposes

In each community-specific Aboriginal and / or Treaty Rights and Interests Impact Assessment Report, a summary of the residual impacts carried forward to the cumulative impact assessment is provided (loss of or physical change to sites and areas used for traditional purposes).

For each identified residual impact carried forward the following assessment sections were completed:

- A description of the potential cumulative effect on rights. For example, three projects identified in the Project Inclusions List overlap with a trapline, and one project overlaps with a trapline within the Regional Study Area.

- A description of the potential cumulative impacts on rights. For example, there are four other developments that could directly impact trapline areas of significance to the First Nation and will result in an incremental loss of the current area available for trapping and other rights-based activities.
- A summary of mitigation measures proposed. For example, notify Indigenous communities and trapline holders of Community Access Road activities, schedules, and locations.
- An assessment of predicted cumulative impacts on rights including context, direction, magnitude, geographic extent, duration, frequency, reversibility, and likelihood.
- An assessment of the severity of the cumulative impacts and associated prediction confidence.

10.4.2.2 Cultural Continuity and Well-being

In each community-specific Aboriginal and / or Treaty Rights and Interests Impact Assessment Report, a summary of the residual impacts carried forward to the cumulative impact assessment is provided (for example, changes in the experience of being on the land).

For each identified residual impact carried forward the following assessment sections were completed:

- A description of the potential cumulative effect on rights. For example, the Community Access Road has the potential to affect the experience of being on the land, in terms of freedom from disturbance, due to changes in the noise environment.
- A description of the potential cumulative impacts on rights. For example, where the Community Access Road and other projects / activities overlap with the First Nation's Area of Interest, the potential effects on the noise environment may be even more pronounced, particularly during concurrent construction activities when adverse effects on this valued component are expected to be greatest. Changes to the noise environment may alter the experience of being on the land.
- A summary of mitigation measures proposed. For example, provide Indigenous communities with advance notices and regular updates regarding location and timing of construction activities, including bridge construction and blasting operations.

- An assessment of predicted residual cumulative impacts on rights including context, project phase(s), direction, magnitude, geographic extent, duration, frequency, reversibility, and likelihood.
- An assessment of the severity of the residual impacts and associated prediction confidence.

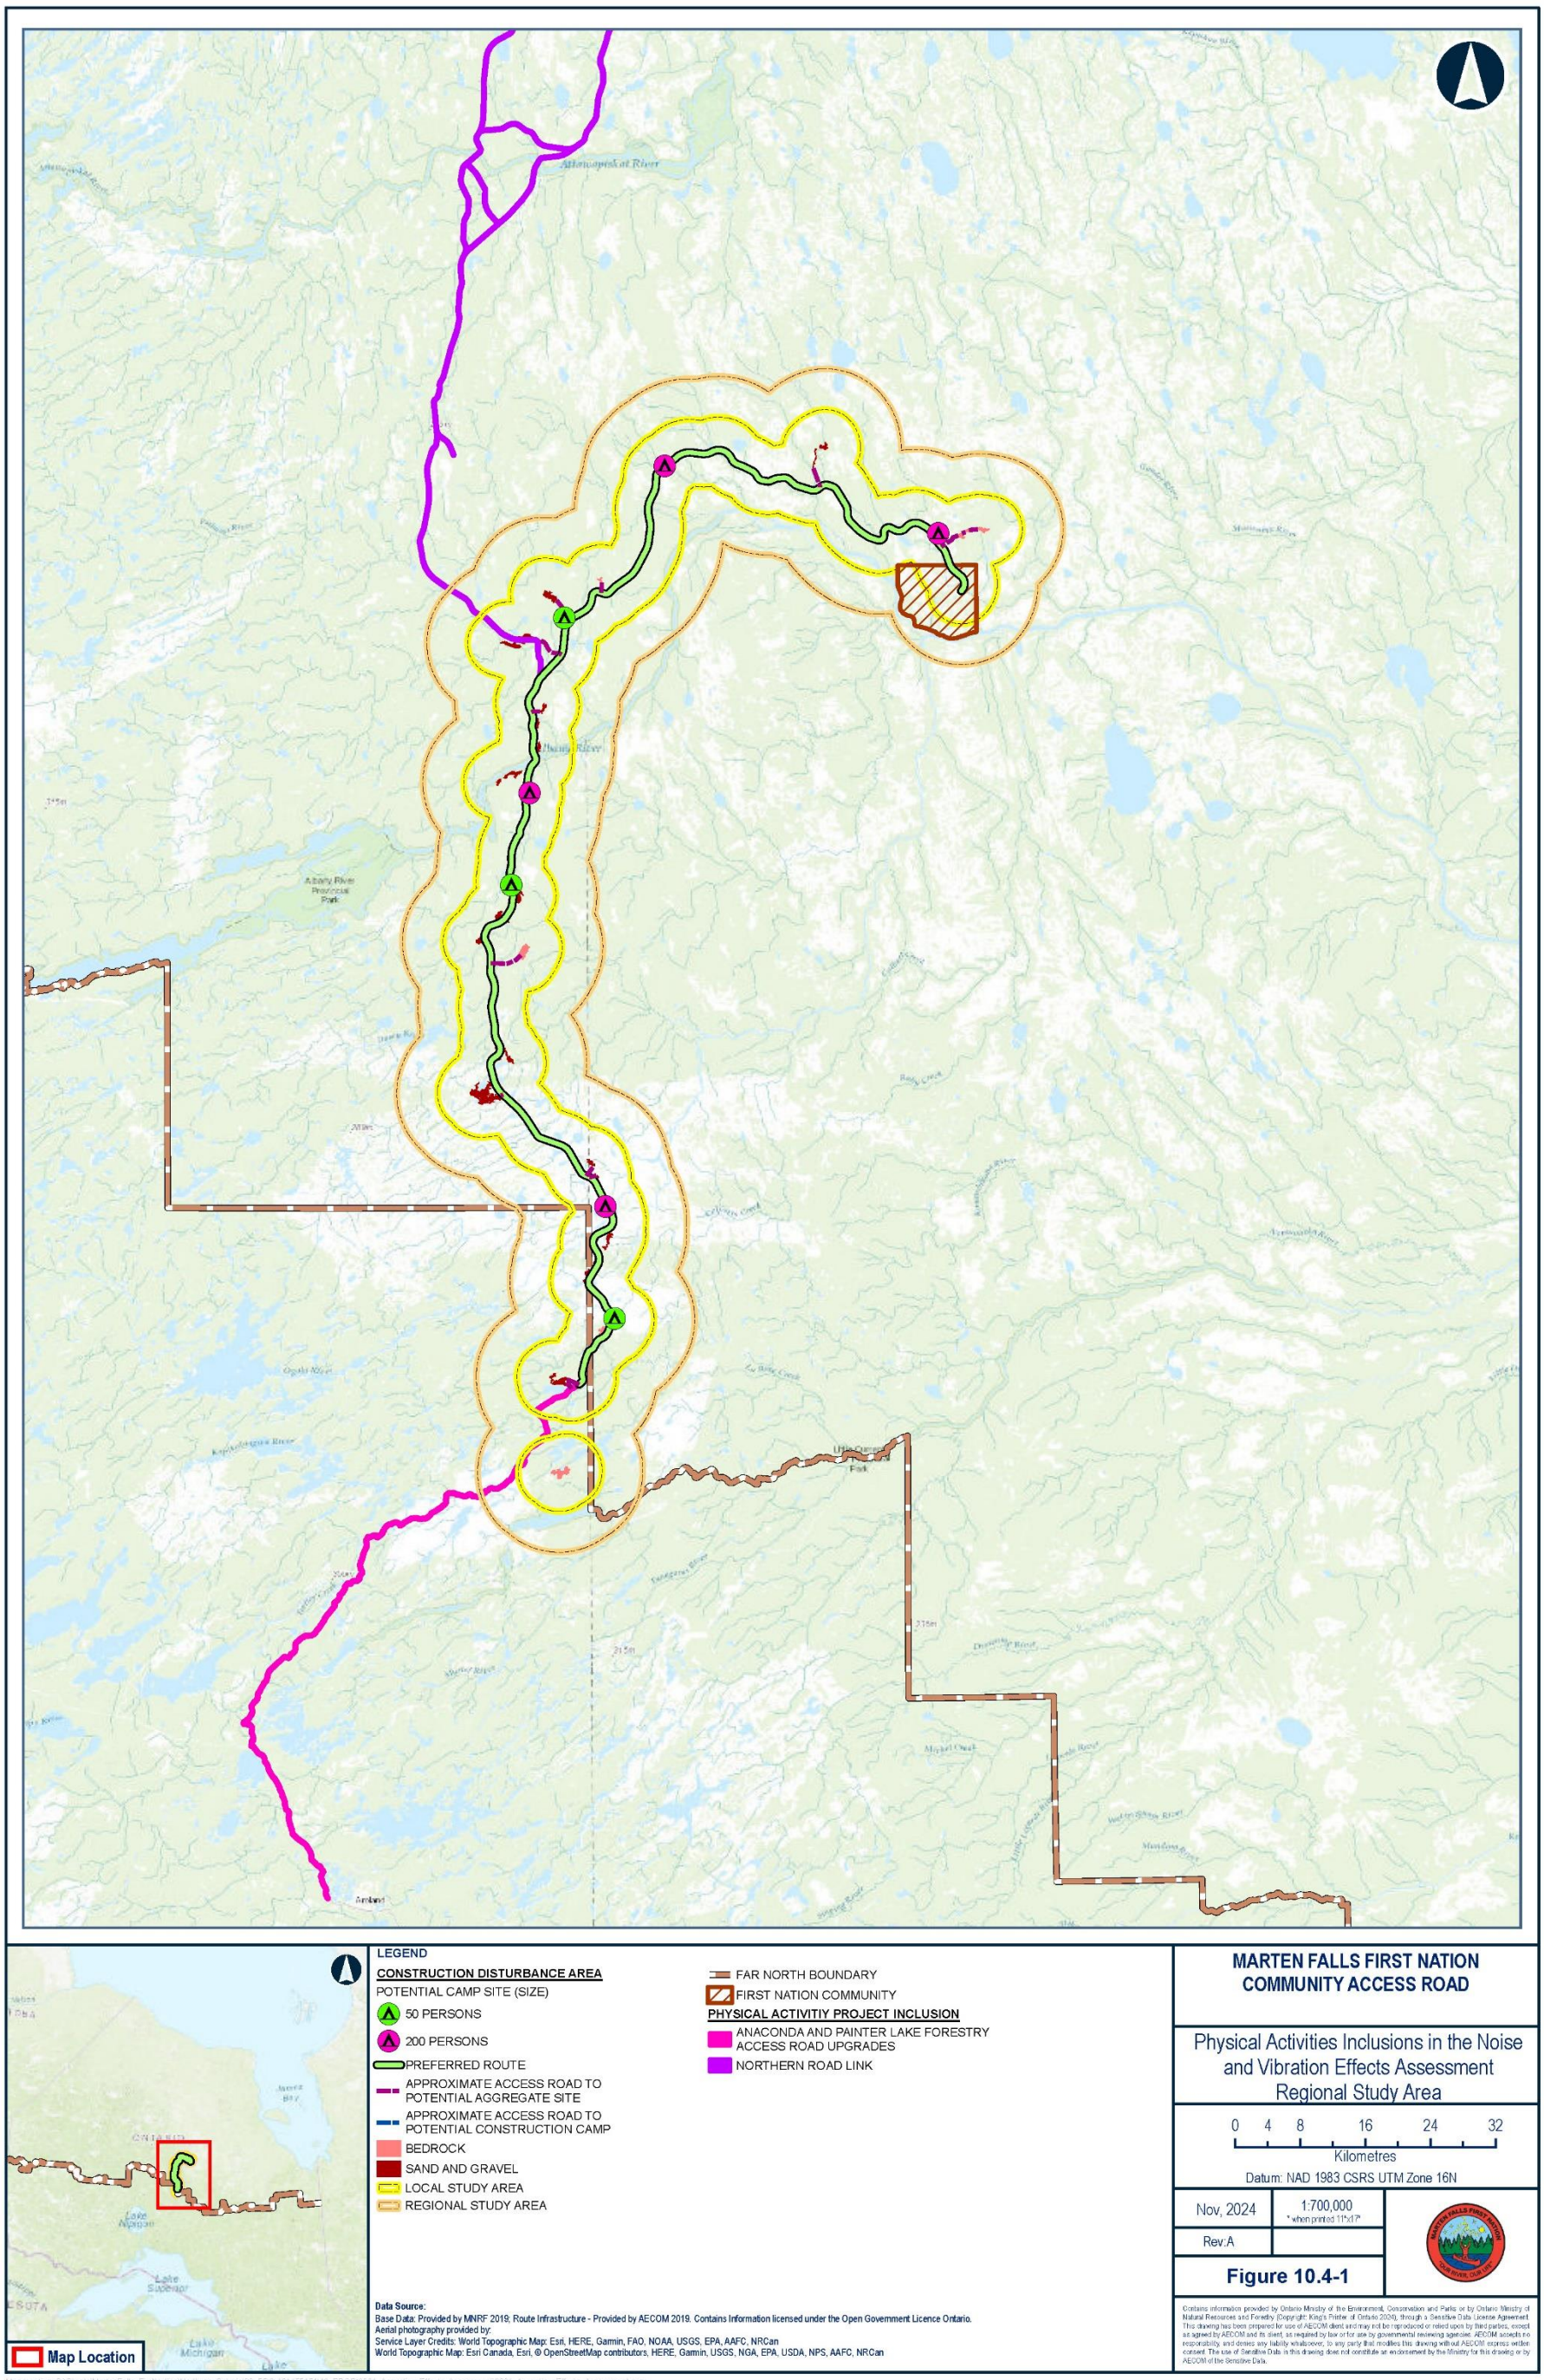
10.4.3 Acoustic and Vibration

Two valued components with residual effects were carried forward to the acoustic and vibration Cumulative Effects Assessment:

- Noise; and
- Vibration.

The locations of the projects considered for the Cumulative Effects Assessment in relation to the noise and vibration Regional Study Area are shown on **Figure 10.4-1**.

10.4.3.1 Noise



The construction and operation of the Northern Road Link, operations of the Anaconda and Painter Lake Forestry Access Road upgrades, and construction and operations of the Community Access Road have the potential for cumulative effects on noise through the use of heavy mobile equipment and road traffic. This is because it is predicted that, after the implementation of impact management measures, exceedances of applicable criteria at potential points of reception may occur.

The magnitude of the cumulative effects from the increased noise during construction and operations, for example, quarry blasting, has the potential to range from low to high, depending on the distance between the points of reception and the construction activities. Therefore, for a conservative assessment, the cumulative effects were assessed to be **high**.

10.4.3.2 Vibration

The construction and operations of the Northern Road Link, operations of the Anaconda and Painter Lake Forestry Access Road upgrades, and construction and operations of the Community Access Road have the potential for cumulative effects on vibration through the use of heavy mobile equipment and blasting. This is because it is predicted that, after the implementation of impact management measures, exceedances of applicable criteria at potential points of reception may occur.

Figure 10.4-1: Physical Activities Inclusions in the Noise and Vibration Effects Assessment Regional Study Area

The magnitude of the cumulative effects from the increased vibration during construction and operations, for example, quarry blasting, has the potential to range from low to high, depending on the distance between the points of reception and the construction activities. Therefore, for a conservative assessment, the cumulative effects were assessed to be **high**.

10.4.3.3 Mitigation Measures

It is anticipated that mitigation measures will be, or have been, implemented to limit noise and vibration levels during the construction and operations of the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades, and that these mitigation measures will be similar to those implemented for the Community Access Road. Refer to **Section 9.5.3** for a complete description of the proposed mitigation measures for Acoustic Environment.

10.4.3.4 Determination of Significance

Significance was determined only for disciplines where it was required to meet federal or provincial requirements. For the purposes of this Cumulative Effects Assessment, significance of the effects for acoustic and vibration was not determined.

10.4.4 Cultural Heritage

No residual effects on cultural heritage valued components were carried forward from the residual effects assessment; therefore, no cumulative effects on built heritage resources and cultural heritage landscapes are anticipated.

10.4.5 Archaeology

No residual effects to archaeology valued components were carried forward from the residual effects assessment; therefore, no cumulative effects on archaeological resources are anticipated.

10.4.6 Atmospheric Environment

10.4.6.1 Air Quality

The only valued components with residual effects carried forward into the Cumulative Effects Assessment for the air quality discipline is changes to air quality.

Detailed operational information, including equipment, operating schedules, and location of activities, are required to estimate emissions from the project activities listed

in the Project Inclusions List. As operational information is not available, a quantitative Cumulative Effects Assessment cannot be completed at this time. Interactions may occur at the north and south ends of the road where the Community Access Road connects with the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades; however, interactions would likely be limited to areas with overlapping spatial and temporal boundaries (in other words, directly adjacent to connection points) and would not extend along the full road corridor.

It is anticipated that each of the projects on the Cumulative Effects Assessment Project Inclusions List contains elements of construction and / or operations that would share the potential for emissions of like contaminants (such as particulates and products of combustion) with the Community Access Road. It should be noted that traffic projections included within this Cumulative Effects Assessment include a forecasted prediction of combined traffic levels from the Northern Road Link and Anaconda and Painter Lake Forestry Access Road upgrades.

Projects in the region with potential overlapping spatial and temporal boundaries with the Community Access Road may have the potential to result to increase the magnitude, frequency, irreversibility, and likelihood of the Community Access Road's residual effects. Significance of effects is unlikely to change from those documented within this Cumulative Effects Assessments.

10.4.6.2 Greenhouse Gas

No residual effects to the greenhouse gas valued components were carried forward from the residual effects assessment; therefore, no cumulative effects as a result of greenhouse gases are anticipated. The Atmospheric Environment Technical Support Document can be found in **Appendix S**. A summary will be provided in the Final Environmental Assessment / Impact Statement.

10.4.7 Community Well-Being

Seven valued components with residual effects were carried forward to the community well-being Cumulative Effects Assessment:

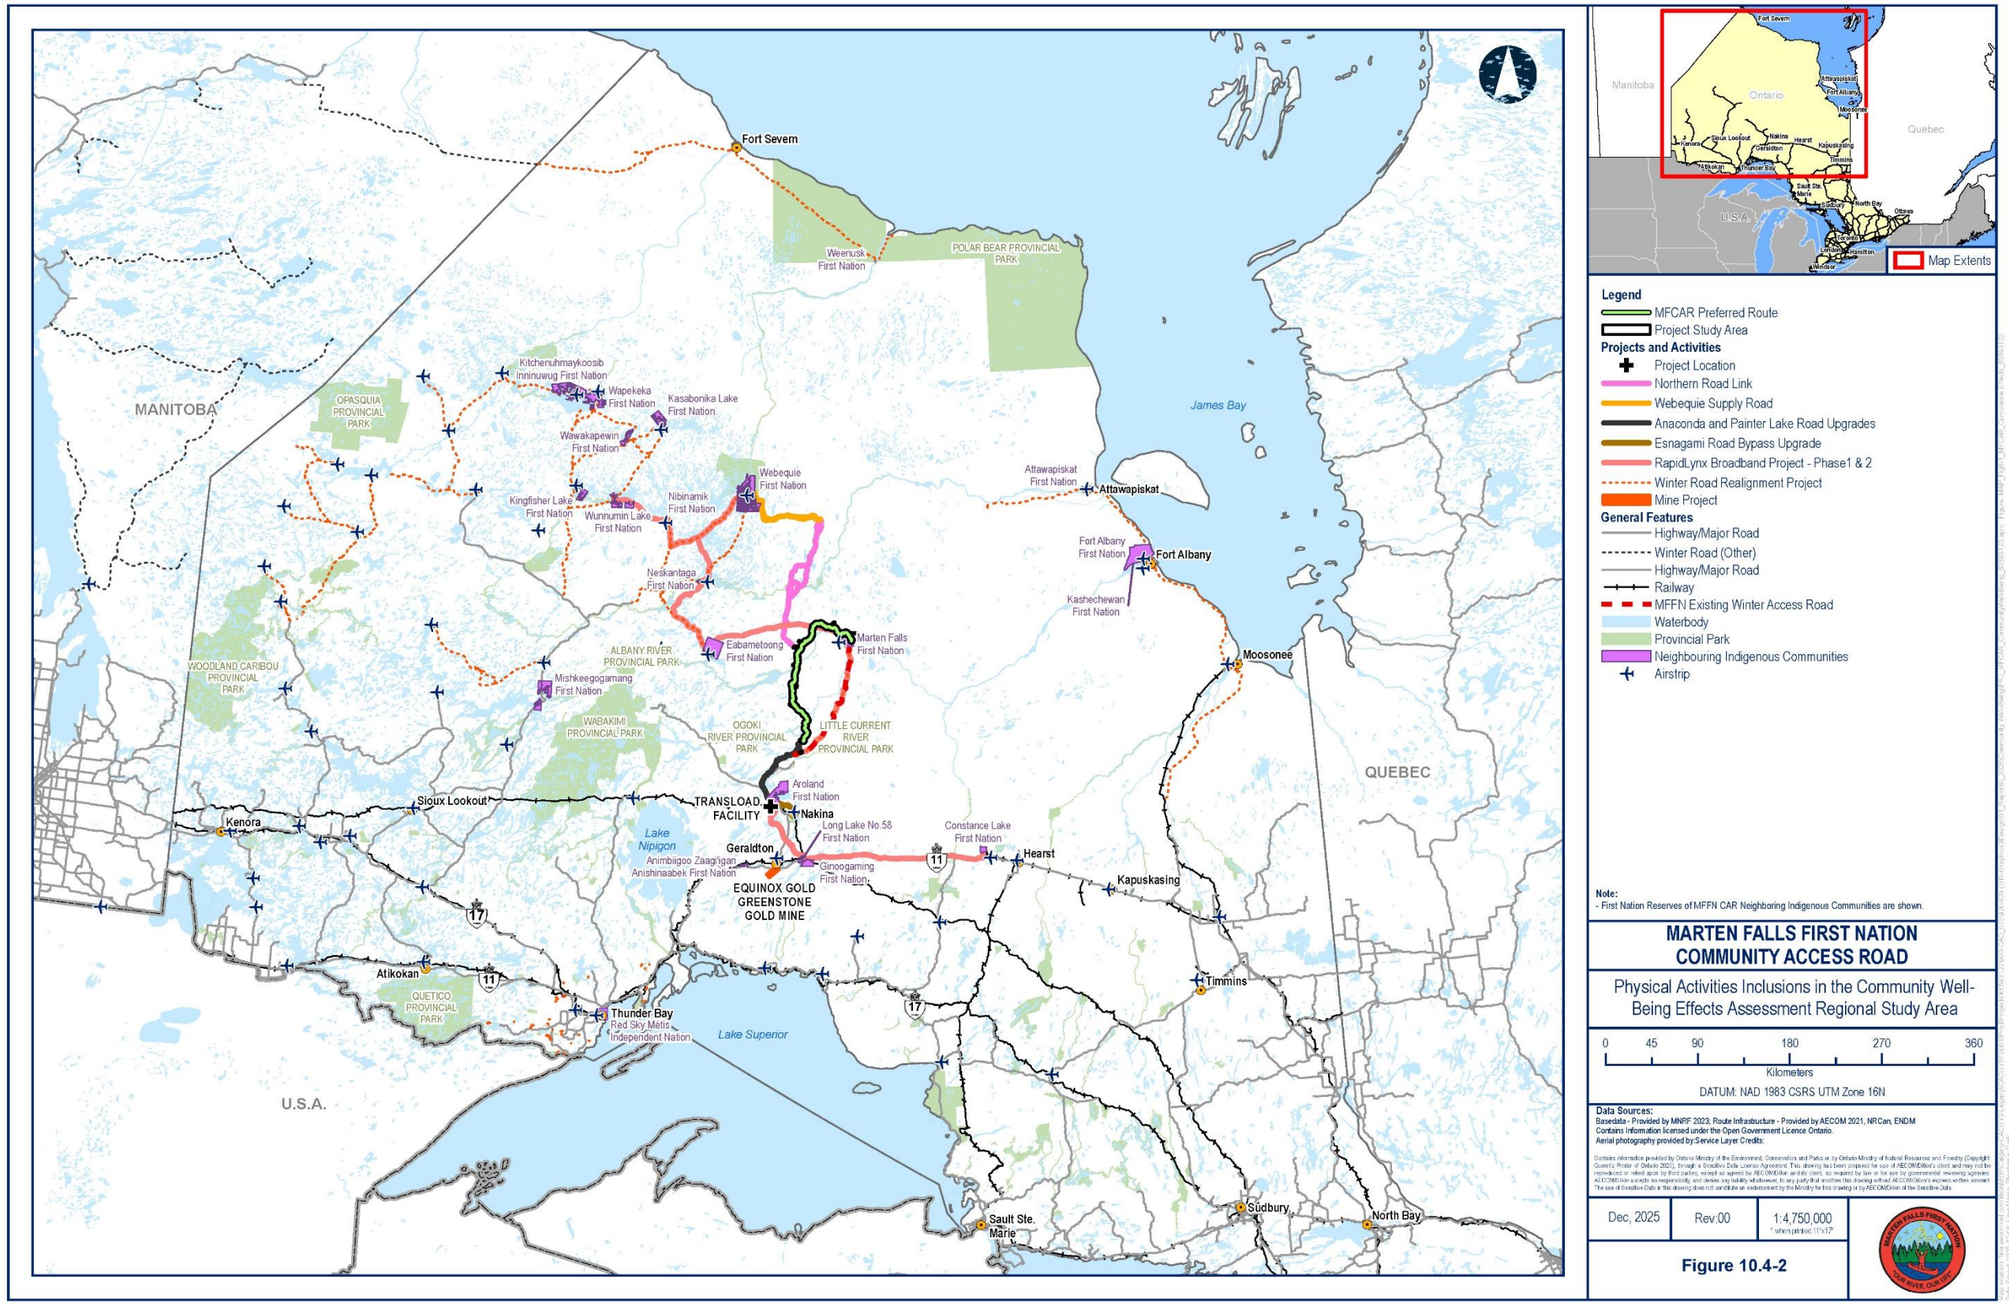
- Community access to infrastructure and services;
- Cultural preservation and change;
- Community and public health;
- Access to clean water;
- Traditional foods;

- Public safety; and
- Biophysical determinants of human health (air).

The locations of the projects considered for the Cumulative Effects Assessment in relation to the community well-being Regional Study Area are shown on **Figure 10.4-2**.

10.4.7.1 Community Access to Infrastructure and Services

The construction and operation of multiple road projects, including the Community Access Road and Northern Road Link, and others, will place increased strain on local transportation networks in the Local Study Area. Construction is expected to increase reliance on winter access roads and air transportation for the mobilization of equipment, supplies, and work force transportation. This increase in use of existing transportation networks may result in potentially negative effects of traffic congestion or scheduling challenges for community members. There may be negative effects related to safety along existing routes, especially for winter access roads, when heavy equipment or large shipments of materials may be brought into community.



It is expected that the negative impacts related to community access will be reduced, but the residual risk will remain elevated due to the sheer volume of traffic associated with multiple projects in the region.

10.4.7.2 Cultural Preservation and Change

The construction of multiple projects, including the Community Access Road, Transload Facility in Aroland, Northern Road Link, and others, could contribute to a disruption to the traditional economy and cultural practices in the Local Study Area due to potential loss of traditional harvesting areas / disturbance in the local construction area. This could also reduce available land for traditional activities within the project footprint. These changes may temporarily alter animal migration paths, disturb vegetation, and could lead to overharvesting of traditional resources in the Local Study Area.

These impacts may be compounded by other projects in the area, including the Northern Road Link, Anaconda and Painter Lake Forestry Access Road upgrades, and others.

Figure 10.4-2: Physical Activities Inclusions in the Community Well-Being Effects Assessment Regional Study Area

10.4.7.3 Community and Public Health

Construction and operation of multiple projects will create overlapping pressures on mental health and well-being. During construction, workers may experience stress and burnout, while community members may face sensory disturbances, restricted land access, and cultural loss. These effects may compound with other projects, amplifying psychosocial challenges, particularly for Indigenous women and youth.

Operations may continue to influence mental health for some individuals, particularly through a diminished sense of connectivity to land and cultural identity. These effects are expected to remain localized to areas where the road corridor exists and may persist as long as the infrastructure remains, though they could be reversible through access to mental health supports and land-based activities.

10.4.7.4 Access to Clean Water

There are possible negative residual cumulative effects on water quality related to access to clean water. Construction and operations and maintenance activities can create air emissions and dust which affects air quality and has the potential to settle on surface water and soils. Additionally accidents and malfunctions could impact air, sediment, soils, surface water and groundwater directly.

10.4.7.5 Traditional Foods

The construction and operation of multiple projects, including the Community Access Road, Northern Road Link, Transload Facility in Aroland, and others, will create overlapping pressures on traditional foods in the Local Study Area. Construction activities, including land clearing for the road corridor, work camps, and pits and quarries, may lead to disturbances that reduce the availability of traditional foods during key harvest seasons. During operations, possible negative residual effects on availability traditional foods include a local decrease in availability of `traditional food resources, due to disruption from the road itself or the result of increased harvesting due to increased access. There may also be a possible negative effect on the quality of traditional foods, due to contamination from construction activities.

10.4.7.6 Public Safety

The construction and operations of the Community Access Road, along with other regional infrastructure projects, will contribute to cumulative public safety concerns, particularly related to road use accidents, emergency service access, and social risks.

During construction, heavy traffic on winter and access roads may raise the risk of accidents despite traffic management plans. Once operational, the shift from a seasonally available winter access road to a year-round route is expected to lead to more accidents due to higher traffic volumes.

The construction and operations of multiple road projects will place increased strain on local healthcare and emergency services. During the construction, increased traffic accidents and injuries could overwhelm local medical providers.

The combined effects of multiple construction and operational activities could contribute to an increase in violence and criminal activity, particularly human trafficking, along these roads. The construction may contribute to these issues due to an influx of workers, long-term family separations, and increased stress, which can elevate the risk of domestic violence. Improved road accessibility may facilitate human trafficking, particularly affecting Indigenous women, girls, boys, and gender-diverse individuals.

10.4.7.7 Biophysical Factors Influencing Human Health

The predominant residual effect is particulate concentrations in air during operations. This would be additive in areas of spatial and temporal overlap. Temporal overlap is anticipated as operations are considered continuous. Refer to **Section 10.4.3** for further details on cumulative effects to the atmospheric environment.

10.4.7.8 Mitigation Measures

To mitigate negative effects on drinking and recreational water:

- Owner / operator to establish working groups with Marten Falls First Nation, Aroland First Nation, and other interested Indigenous communities from the Regional Study Area, including Constance Lake, Neskantaga, Animbiigoo Zaagi'igan Anishinaabek, Attawapiskat, Kashechewan, and Fort Albany First Nations, to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including concerns related to contamination of ground and surface water.
- Surface water and groundwater will not be used as a drinking water source without appropriate treatment.
- Best practices for construction and operations will be used to minimize dust formation and to reduce the risks of accidents or malfunctions.

To address potential effects related to public safety, a mitigation measure has been identified that the owner / operator will establish a working group with Marten Falls First

Nation, Aroland First Nation, and the owner / operator to meet regularly and discuss issues such as driver's license accessibility, road safety training, and risks of increased violence.

No additional mitigation or enhancement measures are proposed as part of the community well-being Cumulative Effects Assessment. Refer to **Section 9.5.6** for a complete description of the proposed mitigation measures for community well-being.

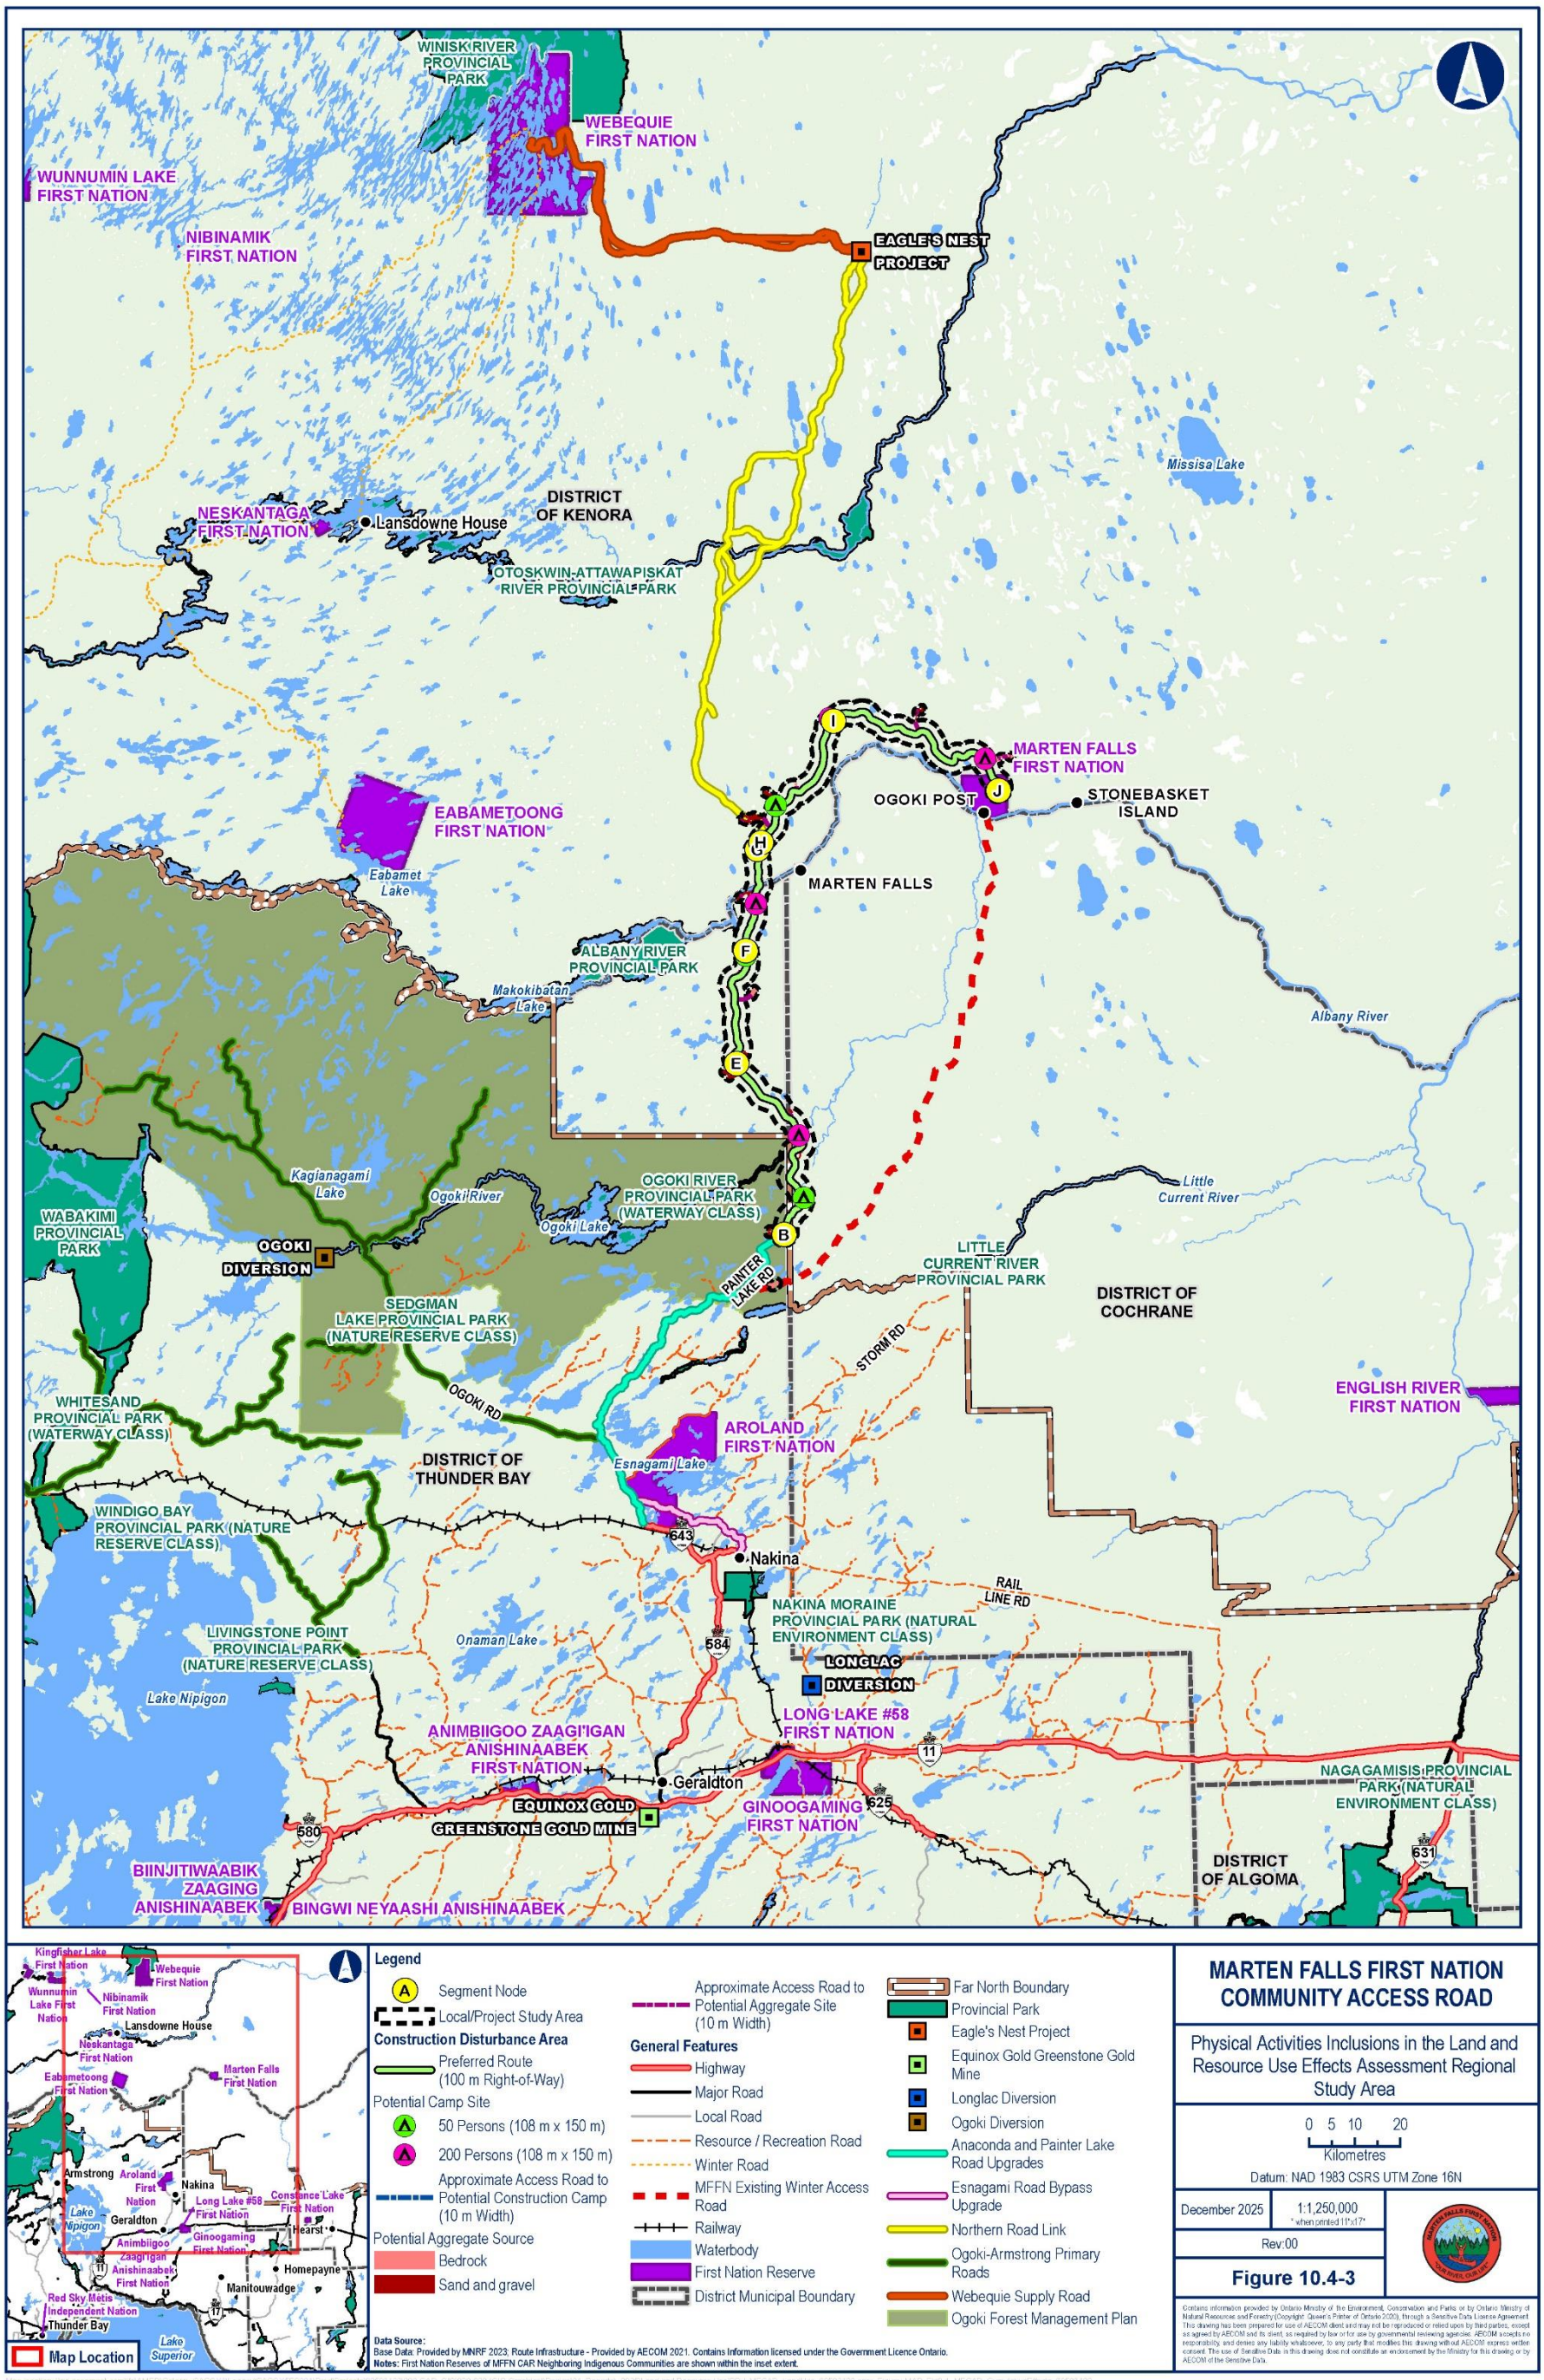
10.4.7.9 Determination of Significance

Significance was determined only for disciplines where it was required to meet federal or provincial requirements. For the purposes of this Cumulative Effects Assessment, significance of the effects for community well-being was not determined.

10.4.8 Land and Resource Use

The only valued components with residual effects carried forward into the Cumulative Effects Assessment for the Land and Resource Use Discipline is trapping.

The locations of the projects considered for the Cumulative Effects Assessment in relation to the Land and Resource Use Regional Study Area are shown on **Figure 10.4-3**.



10.4.8.1 Trapping

There is potential for cumulative effects on trapping within three trapline areas (GE148, GE153, and GE154) due to the combined presence of the Community Access Road and the Northern Road Link. These effects are primarily related to habitat loss for furbearing species and disturbances during construction and operations of the projects, specifically these projects could increase the area of land that is temporarily or permanently less suitable for trapping in proximity to the road corridors.

Conversely, the Northern Road Link would also improve access to trapline areas, which may provide a benefit to trapping activities by reducing travel time and effort.

As no feedback was received from registered trapline holders or helpers, the extent to which increased access or disturbance may influence trapping activities remains uncertain.

Figure 10.4-3: Physical Activities Inclusions in the Land and Resource Use Effects Assessment Regional Study Area

10.4.8.2 Mitigation Measures

The following mitigation measures are proposed to manage potential cumulative effects to land and resource use:

- Communicate with trapline holder in advance of and during construction through multiple efforts such as letters, signage around the future Construction Disturbance Area.
- Permit travel through the project corridor by the trapper during construction.
- Same mitigation measures previously outlined for the trapping valued component (**Section 9.5.7.3.7**).

10.4.8.3 Determination of Significance

The combined area of habitat removal and disturbance associated with both projects represents a small proportion of the overall trapline areas. Considering the limited spatial overlap, the localized nature of effects, and the uncertainty regarding actual trapping activity levels, cumulative effects on trapping are assessed as low to moderate in magnitude and **not significant.**

10.4.9 Visual

Four valued components with residual effects were carried forward to the visual environment Cumulative Effects Assessment.

- Changes to cultural heritage resources and indigenous experience and sense of place visual environment;
- Changes to recreation and tourism visual environment;
- Changes to parks and protected areas visual environment; and,
- Changes to permanent settlements visual environment.

10.4.9.1 Cultural Heritage Resources and Indigenous Experience and Sense of Place Visual Environment

It is expected that there will be localized, short-term visual change at the Albany River and Ogoki River crossings, and other major crossings during construction; however, these changes are not anticipated to be significant during operations.

Cumulative visual magnitude is low to moderate where projects spatially overlap; these overlap areas generally do not coincide with major river crossings and are typically in

forested settings. With feathered clearing edges, natural regeneration of temporary disturbance areas, and lighting restrictions, cumulative visual effects remain localized and limited in duration. The resulting cumulative effect is **not significant** overall for this valued component.

10.4.9.2 Recreation and Tourism Visual Environment

It is expected that there will be localized and temporary visual changes during active construction at major river crossings, with effects confined to crossing viewsheds and experienced intermittently by users; however, these changes are not anticipated to be significant for broader recreation and tourism setting during construction and operations.

Where construction activities or bridge structures from multiple projects may be visible concurrently, visual disturbance may be temporarily intensified within localized portions of travel corridors. However, cumulative magnitude remains low to moderate, spatially confined, and short-term in nature. At the recreation-use scale, cumulative visual effects are **not significant.**

10.4.9.3 Parks and Protected Areas Visual Environment

It is expected that there will be temporary, localized visual change within crossing view cones during construction, confined to the visual Construction Disturbance Area. At the park scale, residual effects on the visual character of Ogoki River Provincial Park and Albany River Provincial Park are not significant during both construction and operations.

Where other projects or activities overlap spatially with the Community Access Road, these overlaps occur outside parks and protected areas. Within park boundaries, cumulative visual magnitude remains low, and cumulative visual effects on protected landscape character are **not significant**.

10.4.9.4 Permanent Settlements Visual Environment

Residual visual effects are not significant for the Community during both construction and operations. For the two Albany River shoreline cabins, visual change may be noticeable during nearby construction activity but is short-term, reversible, spatially limited, and **not significant** overall.

There are no other past, present, or reasonably foreseeable projects or activities expected to interact visually with the Community Access Road in the vicinity of the Community or the two Albany River shoreline cabins. As such, no cumulative visual effects are anticipated for permanent settlements.

10.4.9.5 Mitigation Measures

The following mitigation measures are proposed to manage potential cumulative effects to the visual environment:

- Align and co-locate laydown and access areas to minimize spatial duplication wherever possible;
- Apply shared colour, texture, and lighting standards across projects to maintain a unified appearance and reduce perceived clutter (especially for crossing structures along the Northern Road Link and Anaconda and Painter Lake Forestry Access Road);
- Allow for regrowth of temporary use areas to hasten the return of natural texture;
- Use full task-specific lighting and dark-sky practices jointly across overlapping projects where possible; and
- Conduct follow-up photo-monitoring where there is physical overlap with the Community Access Road, with adaptive planting or screening if visual contrast remains above prediction after Year 3 or if complaints are received from the community.

10.4.9.6 Determination of Significance

The cumulative effects of the Community Access Road in combination with the other activities / projects are assessed as **not significant** with a moderate to high level of confidence for the visual environment. This determination is based on the following considerations:

- The spatial overlap of visible Project components with other physical activities is limited and occurs primarily at a regional scale rather than within shared local viewsheds;
- Where cumulative visibility may occur, effects are largely confined to linear corridors and isolated river crossing locations;
- The magnitude of residual visual effects from the Community Access Road is low, with medium magnitude effects limited to very close-range viewpoints;
- Similar mitigation measures are applied across projects, reducing the likelihood of compounding visual contrast or widespread alteration of landscape character; and
- The overall scenic integrity, wilderness character, and sense of remoteness that define the regional visual environment are maintained.

Although the visual environment is characterized by high sensitivity, the limited extent, low magnitude, and localized nature of overlapping effects prevent cumulative visual effects from resulting in a meaningful or sustained change to landscape character, Indigenous experience and sense of place, recreation and tourism values, protected area aesthetics, or visual conditions experienced by permanent residents.

10.4.10 Summary of Cumulative Effects

Table 10.4-3 summarizes the cumulative effects for the people disciplines.

Table 10.4-3: Summary of Predicted Cumulative Effects for People Disciplines

Discipline	Valued Component	Cumulative Effect	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Probability of Occurrence	Significance (Significant, Not Significant)	Uncertainty
Aboriginal and Treaty Rights and Interests	Aboriginal and Treaty Rights and Interests	Indigenous Current Use of Lands and Resources for Traditional Purposes	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable
Aboriginal and Treaty Rights and Interests	Aboriginal and Treaty Rights and Interests	Cultural Continuity and Well-being	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable
Acoustic and Vibration	Noise	Increase in noise level during construction	Negative	High	Local	Short-term	Infrequent	Reversible	Certain	Not Applicable	Moderate
Acoustic and Vibration	Noise	Increase in noise level during operation (road / quarry)	Negative	Low / High	Local	Long-term	Frequent / Infrequent	Reversible	Certain	Not Applicable	Moderate
Acoustic and Vibration	Vibration	Increase in vibration level during construction	Negative	High	Local	Short-term	Infrequent	Reversible	Certain	Not Applicable	Moderate
Acoustic and Vibration	Vibration	Increase in vibration level during operation	Negative	High	Local	Short-term	Infrequent	Reversible	Certain	Not Applicable	Moderate

Visual	Cultural Heritage Resources and Indigenous Experience and Sense of Place	Changes to views with Cultural Heritage Resource Value, or those that contribute to Indigenous Experience and Sense of Place	Negative	Low	Local	Long-term	Infrequent for land users and community receptors; continuous at the landscape scale during active construction and operations.	Partially reversible through vegetation regrowth and reclamation; permanent for bridge and road forms.	Certain	Not Significant	Low / Moderate
Visual	Recreation and Tourism	Changes to views from areas that provide recreation and tourism value	Negative	Low	Local	Long-term	Infrequent for land users and community receptors; continuous at the landscape scale during active construction and operations.	Partially reversible through vegetation regrowth and reclamation; permanent for bridge and road forms.	Certain	Not Significant	Low / Moderate
Visual	Parks and Protected Areas	Changes to park landscape character and park viewscapes	Not applicable	Low	Local	Long-term	Infrequent for land users and community receptors; continuous at the landscape scale during active construction and operations.	Partially reversible through vegetation regrowth and reclamation; permanent for bridge and road forms.	Certain	Not Significant	Low / Moderate
Visual	Permanent Settlements	Changes to views from permanent settlement	Negative	Low	Local	Long-term	Infrequent for land users and community receptors; continuous at the landscape scale during active construction and operations.	Partially reversible through vegetation regrowth and reclamation; permanent for bridge and road forms.	Certain	Not Significant	Low / Moderate

11. We Listened

11.1 Introduction

This section provides a summary of consultation and engagement activities led by Marten Falls First Nation to inform the Final Environmental Assessment / Impact Statement. The reporting period began with the release of the Notice of Commencement of Environmental Assessment on October 29, 2021, (Marten Falls First Nation, 2021), and extends to September 5, 2025. Additional activities up to the submission of the Final Environmental Assessment / Impact Statement are also captured.

Consultation and engagement activities conducted during the Environmental Assessment / Impact Assessment (Assessment Process) followed the structure outlined in the Consultation and Engagement Plan (Terms of Reference AECOM, 2020c). Consultation and engagement were organized around the four key milestones of the Assessment Process:

- Milestone 1: Notice of Commencement of Environmental Assessment;
- Milestone 2: Effects Assessment Methods;
- Milestone 3: Identification of Preferred Alternatives; and
- Milestone 4: Review of the Draft Environmental Assessment / Impact Statement.

Consultation and engagement associated with Milestone 5: Review of Final Environmental Assessment / Impact Statement will be led by the federal and provincial government agencies, as shown in **Figure 11-1**, with support from the Proponent up to the regulators' decision.

Figure 11-1: Milestones and Consultation and Engagement Reporting

In addition to milestone-based consultation and engagement activities, Marten Falls First Nation conducted consultation related to supplemental project deliverables and technical materials throughout the Assessment Process. This included the release of Milestone Progress Reports (Progress Report 1 in December 2022, Progress Report 2 in November 2023, Progress Report 3 in November 2024, and Progress Report 4 in January 2026), as well as technical documents such as the Stage 1 and Stage 2 Archaeological Assessment Reports (February 2023), the Draft Preliminary Aboriginal and / or Treaty Rights and Interests Existing Conditions Report (November 2023), Stage 1 Archaeological Assessment Report (June 2024), and the voluntary Draft Environmental Assessment / Impact Statement (April 2025). In 2025, the Project Team also released the Draft Community Well-Being Report (April 2025) and the Indigenous community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports (July 2025).

Throughout the Assessment Process, consultation and engagement evolved significantly. Early outreach took place under pandemic-related constraints, during which some communities did not respond or expressed concerns or opposition. Over time, however, sustained engagement supported the establishment of clearer communication pathways, increased participation, and more community-specific dialogue. This included strengthening relationships with neighbouring Indigenous communities through frequent communications, targeted engagement activities, and continued availability for meetings and discussions.

Relationship-building was supported by Council-to-Council meetings, including between Marten Falls First Nation and communities such as Eabametoong First Nation and / or Aroland First Nation, where relationship protocols, consultation approaches, and project updates were discussed. Engagement with Aroland First Nation included multiple community meetings, detailed technical discussions during Milestones 3 and 4, and the

creation of a joint task force in 2024. Engagement with Eabametoong First Nation increased through renewed communications, interest in capacity funding, and participation in review of the Draft Environmental Assessment / Impact Statement.

Provincially-supported forums have been another successful approach to consultation and engagement. These offer a space for Indigenous communities, including Elders, to gather over several days to learn about the Community Access Road and the other two road projects in the area, the Northern Road Link and the Webequie Supply Road. The first two forums focused on Aboriginal and / or Treaty Rights and Interests and the third and fourth forums focused on key topics of interest (as identified by neighbouring Indigenous communities) including peatlands, wildlife, cumulative effects, Aboriginal and / or Treaty Rights and Interests, and impacts on caribou and moose. Information was conveyed and / or discussed through topic-centred booths, presentations, and individual breakout rooms with Indigenous communities to discuss topics of most interest to them.

Consultation and engagement were further strengthened through targeted capacity funding supports designed to encourage meaningful participation by eligible Indigenous communities. Throughout the Assessment Process, the Project Team offered two key programs: the Indigenous Knowledge Program, which provided funding and formal Sharing Agreements to communities that chose to contribute Indigenous Knowledge and land and resource use information; and the Community Coordinator Program, which later transitioned into the Community Capacity Funding Program in November 2024. Funding was provided to support activities such as document review, participation in meetings and workshops, logistics, internal coordination, and preparation of community-specific input.

Marten Falls First Nation members contributed Indigenous Knowledge, land and resource use information, and feedback on existing conditions and areas of concern. Community members participated in the evaluation of route alternatives, supported the development of preliminary route recommendations, and reviewed the technically Preferred Route. This engagement culminated in a Band Council Resolution supporting the Preferred Route in August 2024, followed by a Band Council Resolution, in February 2026, endorsing the Final Environmental Assessment / Impact Statement.

A comprehensive Record of Consultation and Engagement accompanies this section. It documents all consultation and engagement activities undertaken by Marten Falls First Nation in support of the Assessment Process. This is a key component of the Final Environmental Assessment / Impact Statement, supporting fulfillment of federal and provincial requirements and commitments set out in the Marten Falls-Ontario Memorandum of Understanding on Shared Consultation Responsibilities. The Record of

Consultation and Engagement describes how input from Indigenous communities, interested persons, and government agencies was sought, received, and considered, demonstrating the Project Team's commitment to meaningful consultation and engagement, transparent decision-making, and regulatory compliance. Prepared at key milestones of the Assessment Process and organized by groups, the Record of Consultation and Engagement (**Appendix X**) provides a clear summary of who participated, what was heard, and how feedback contributed to the development of the Community Access Road.

Section 11 – We Listened includes the following**:**

- **Section 11.1**: introduction;
- **Section 11.2**: federal and provincial requirements;
- **Section 11.3**: who we engaged and why – identification of audiences (Marten Falls First Nation, neighbouring Indigenous communities, interested persons, and government agencies);
  - **Section 11.3.3**: participation in the Indigenous Knowledge Program;
  - **Section 11.3.4**: participation in the Community Coordinator Program;
- **Section 11.4**: consultation and engagement milestones, input, and timing;
- **Section 11.5**: description of consultation and engagement activities across all audiences (Milestones 1, 2, 3, and 4);
- **Section 11.6**: consultation and engagement for the Draft Environmental Assessment / Impact Statement;
- **Section 11.7**: description of consultation and engagement that was unique to each audience and a high-level summary of feedback;
  - **Section 11.7.1**: activities snapshot;
  - **Section 11.7.2**: consultation and engagement with Indigenous communities;
  - **Section 11.7.3**: consultation and engagement with interested persons;
  - **Section 11.7.4**: consultation and engagement with government agencies;
- **Section 11.8**: consideration of identity and Gender-Based Analysis Plus;
- **Section 11.9**: consultation and engagement after September 5, 2025, up to February 2026 (submission of the Final Environmental Assessment / Impact Statement);
- **Section 11.10**: ongoing and future consultation and engagement;

- **Section 11.11**: summary of the Record of Consultation and Engagement; and
- **Section 11.12**: issue resolution.

11.2 Federal and Provincial Requirements

There are both federal and provincial requirements that set the framework for the Assessment Process. These are summarized below and were used to inform the Consultation and Engagement Plan developed during the Terms of Reference to guide communications, engagement, and consultation related to the Community Access Road.

11.2.1 Federal Requirements

Federal requirements for consultation and engagement on the Community Access Road are outlined in the following documents:

- Tailored Impact Statement Guidelines (Impact Assessment Agency of Canada, 2020a);
- Public Participation Plan for the Marten Falls Community Access Road Project Impact Assessment (Impact Assessment Agency of Canada, 2020c); and
- Indigenous Engagement and Partnership Plan for the Marten Falls Community Access Road Project (Impact Assessment Agency of Canada, 2021).

In addition, the Tailored Impact Statement Guidelines require Gender-Based Analysis Plus to be applied to impact assessments in Canada. **Section 11.8** provides information on how this has been applied to the Community Access Road.

11.2.2 Provincial Requirements

The Marten Falls-Ontario Memorandum of Understanding on Shared Consultation Responsibilities (AECOM, 2020) was signed in January 2020 between Marten Falls First Nation and the Province of Ontario. The Memorandum outlines shared responsibilities regarding the procedural aspects of Ontario's duty to consult in the context of the provincial Environmental Assessment for the proposed Community Access Road, for potentially impacted and interested Indigenous communities. Roles and responsibilities governed by the Memorandum include consultation planning and notification, delivery of the planned activities, issues resolution and follow-up, and record keeping for consultation and engagement with Indigenous communities.

A Terms of Reference is the first step in the provincial environmental assessment process and is a roadmap for planning and decision-making. It outlines how an environmental assessment should be prepared, including the studies to be conducted, the process for identifying and assessing the effects of a proposed project, and how people should be consulted.

The Terms of Reference for the Community Access Road was prepared in accordance with the provincial *Environmental Assessment Act* (Government of Ontario, 1990a) and the Code of Practice: Preparing and Reviewing Terms of Reference for the Environmental Assessments in Ontario (Ministry of the Environment, Conservation and Parks 2014); it was submitted to the Ontario Ministry of the Environment, Conservation and Parks on October 23, 2020.

The Terms of Reference includes the Consultation and Engagement Plan (AECOM, 2020c), which was used to guide consultation and engagement efforts throughout the Assessment Process. This document serves as a useful reference, particularly the following sections:

- **Section 2.1:** Principles of Consultation (guiding principles of the Marten Falls First Nation Community-Based Land Use Planning Team for Community Access Road consultation and engagement);
- **Section 2.2:** Nishnawbe Aski Nation's Consultation Policy; and
- **Section 2.3:** Duty to Consult (provincial requirements).

The Terms of Reference was approved with amendments on October 8, 2021, and the Notice of Commencement of the provincial Environmental Assessment for the Community Access Road was posted on October 29, 2021.

As part of the Terms of Reference - Notice of Approval, Ontario's Minister of the Environment, Conservation and Parks included an amendment requiring three additional consultation and engagement reports with Indigenous communities (for example, Milestone Progress Reports), at the environmental assessment milestones noted below. This additional reporting was intended to support Indigenous communities in providing meaningful input during the development of the Environmental Assessment for the Community Access Road.

Each progress report was required to:

- Be organized by each Indigenous community;
- Contain a consultation and engagement log and summary that tracks consultation and engagement activities, information shared by the Project Team

with Indigenous communities, and community input and the Project Team's responses to such input for the environmental assessment milestone; and

- Contain a discussion of how input and information provided by the Indigenous communities have informed the development of the environmental assessment milestone.

The progress reports met the requirements noted above and community-specific sections were distributed to each individual Indigenous community for their review and comment. Each progress report was also shared with the Ministry of the Environment, Conservation and Parks.

A fourth progress report was also provided to Indigenous communities. Progress Report 4 was the last of the four consultation and engagement reports that now collectively make up the Record of Consultation and Engagement for Indigenous Communities for the Environmental Assessment / Impact Statement. While a separate Progress Report 4 was not mandated, its inclusion reflects Marten Falls First Nation's commitment to transparency and meaningful consultation and engagement.

Also, when the Terms of Reference was approved by the Minister of the Environment, Conservation and Parks, additional requirements for consultation with Indigenous communities with respect to the cumulative effects assessment were included. The following amendments were required:

Amendment 1.1:

- Consult with Indigenous communities on the cumulative effects assessment work plan, methodology, results, and impact management measures;
- Offer targeted consultation opportunities to each Indigenous community; and
- Consider any consultation activities / tools that Indigenous communities request to facilitate the consultation required.

Amendment 1.4:

- Develop a Cumulative Effects Consultation Report that includes:
  - A summary of the consultation completed with Indigenous communities and any other organizations / agencies regarding the development of the cumulative effects assessment; and
  - A comment-response table(s) showing how comments from Indigenous communities and any other organizations / agencies were considered and incorporated, as appropriate, in the development of the cumulative effects assessment.

The Cumulative Effects Consultation Report is available in **Appendix X**, detailing activities conducted, and input received throughout all phases of the Assessment Process.

Provincial requirements were inclusive of all federal requirements, and both were met during the Assessment Process. Additional requirements outlined in the Marten Falls-Ontario Memorandum of Understanding on Shared Consultation Responsibilities were also met.

11.3 Who We Engaged and Why

This section describes the audiences engaged for the proposed Community Access Road, how they were identified, and the criteria used to tailor the frequency and depth of engagement.

11.3.1 Marten Falls First Nation

Marten Falls First Nation is both the Proponent of the proposed Community Access Road and the community most directly affected by its development. As Proponent participating in a community-led process, Marten Falls First Nation formed a Project Team that acts with guidance, direction, and input from Chief and Council, Senior Community Member Advisors, and membership. This governance structure helped to ensure Marten Falls First Nation priorities and knowledge guided the Community Access Road.

With Marten Falls First Nation as the Proponent, the Assessment Process was guided by the interests, priorities, and well-being of the Community. Their approach to consultation and engagement was also grounded in the Marten Falls-Ontario Memorandum of Understanding on Shared Consultation Responsibilities, which outlines how the Province and Marten Falls First Nation share procedural aspects of Ontario's duty to consult during the provincial environmental assessment process. With their distinct role, additional opportunities were offered to provide input, review documents, and meet ahead of broader distribution to neighbouring[1] Indigenous communities, interested persons, and government agencies. Feedback from Marten Falls First Nation regularly contributed to the development of consultation, engagement, and communication materials, including Public Information Centres, discussion guides, webinars and video content.

1. The term "neighbouring" is used to identify any Indigenous community being consulted and engaged with respect to the Community Access Road; the term is not in reference to proximity. Marten Falls First Nation is regarded as both a neighbouring Indigenous community and as the Proponent.

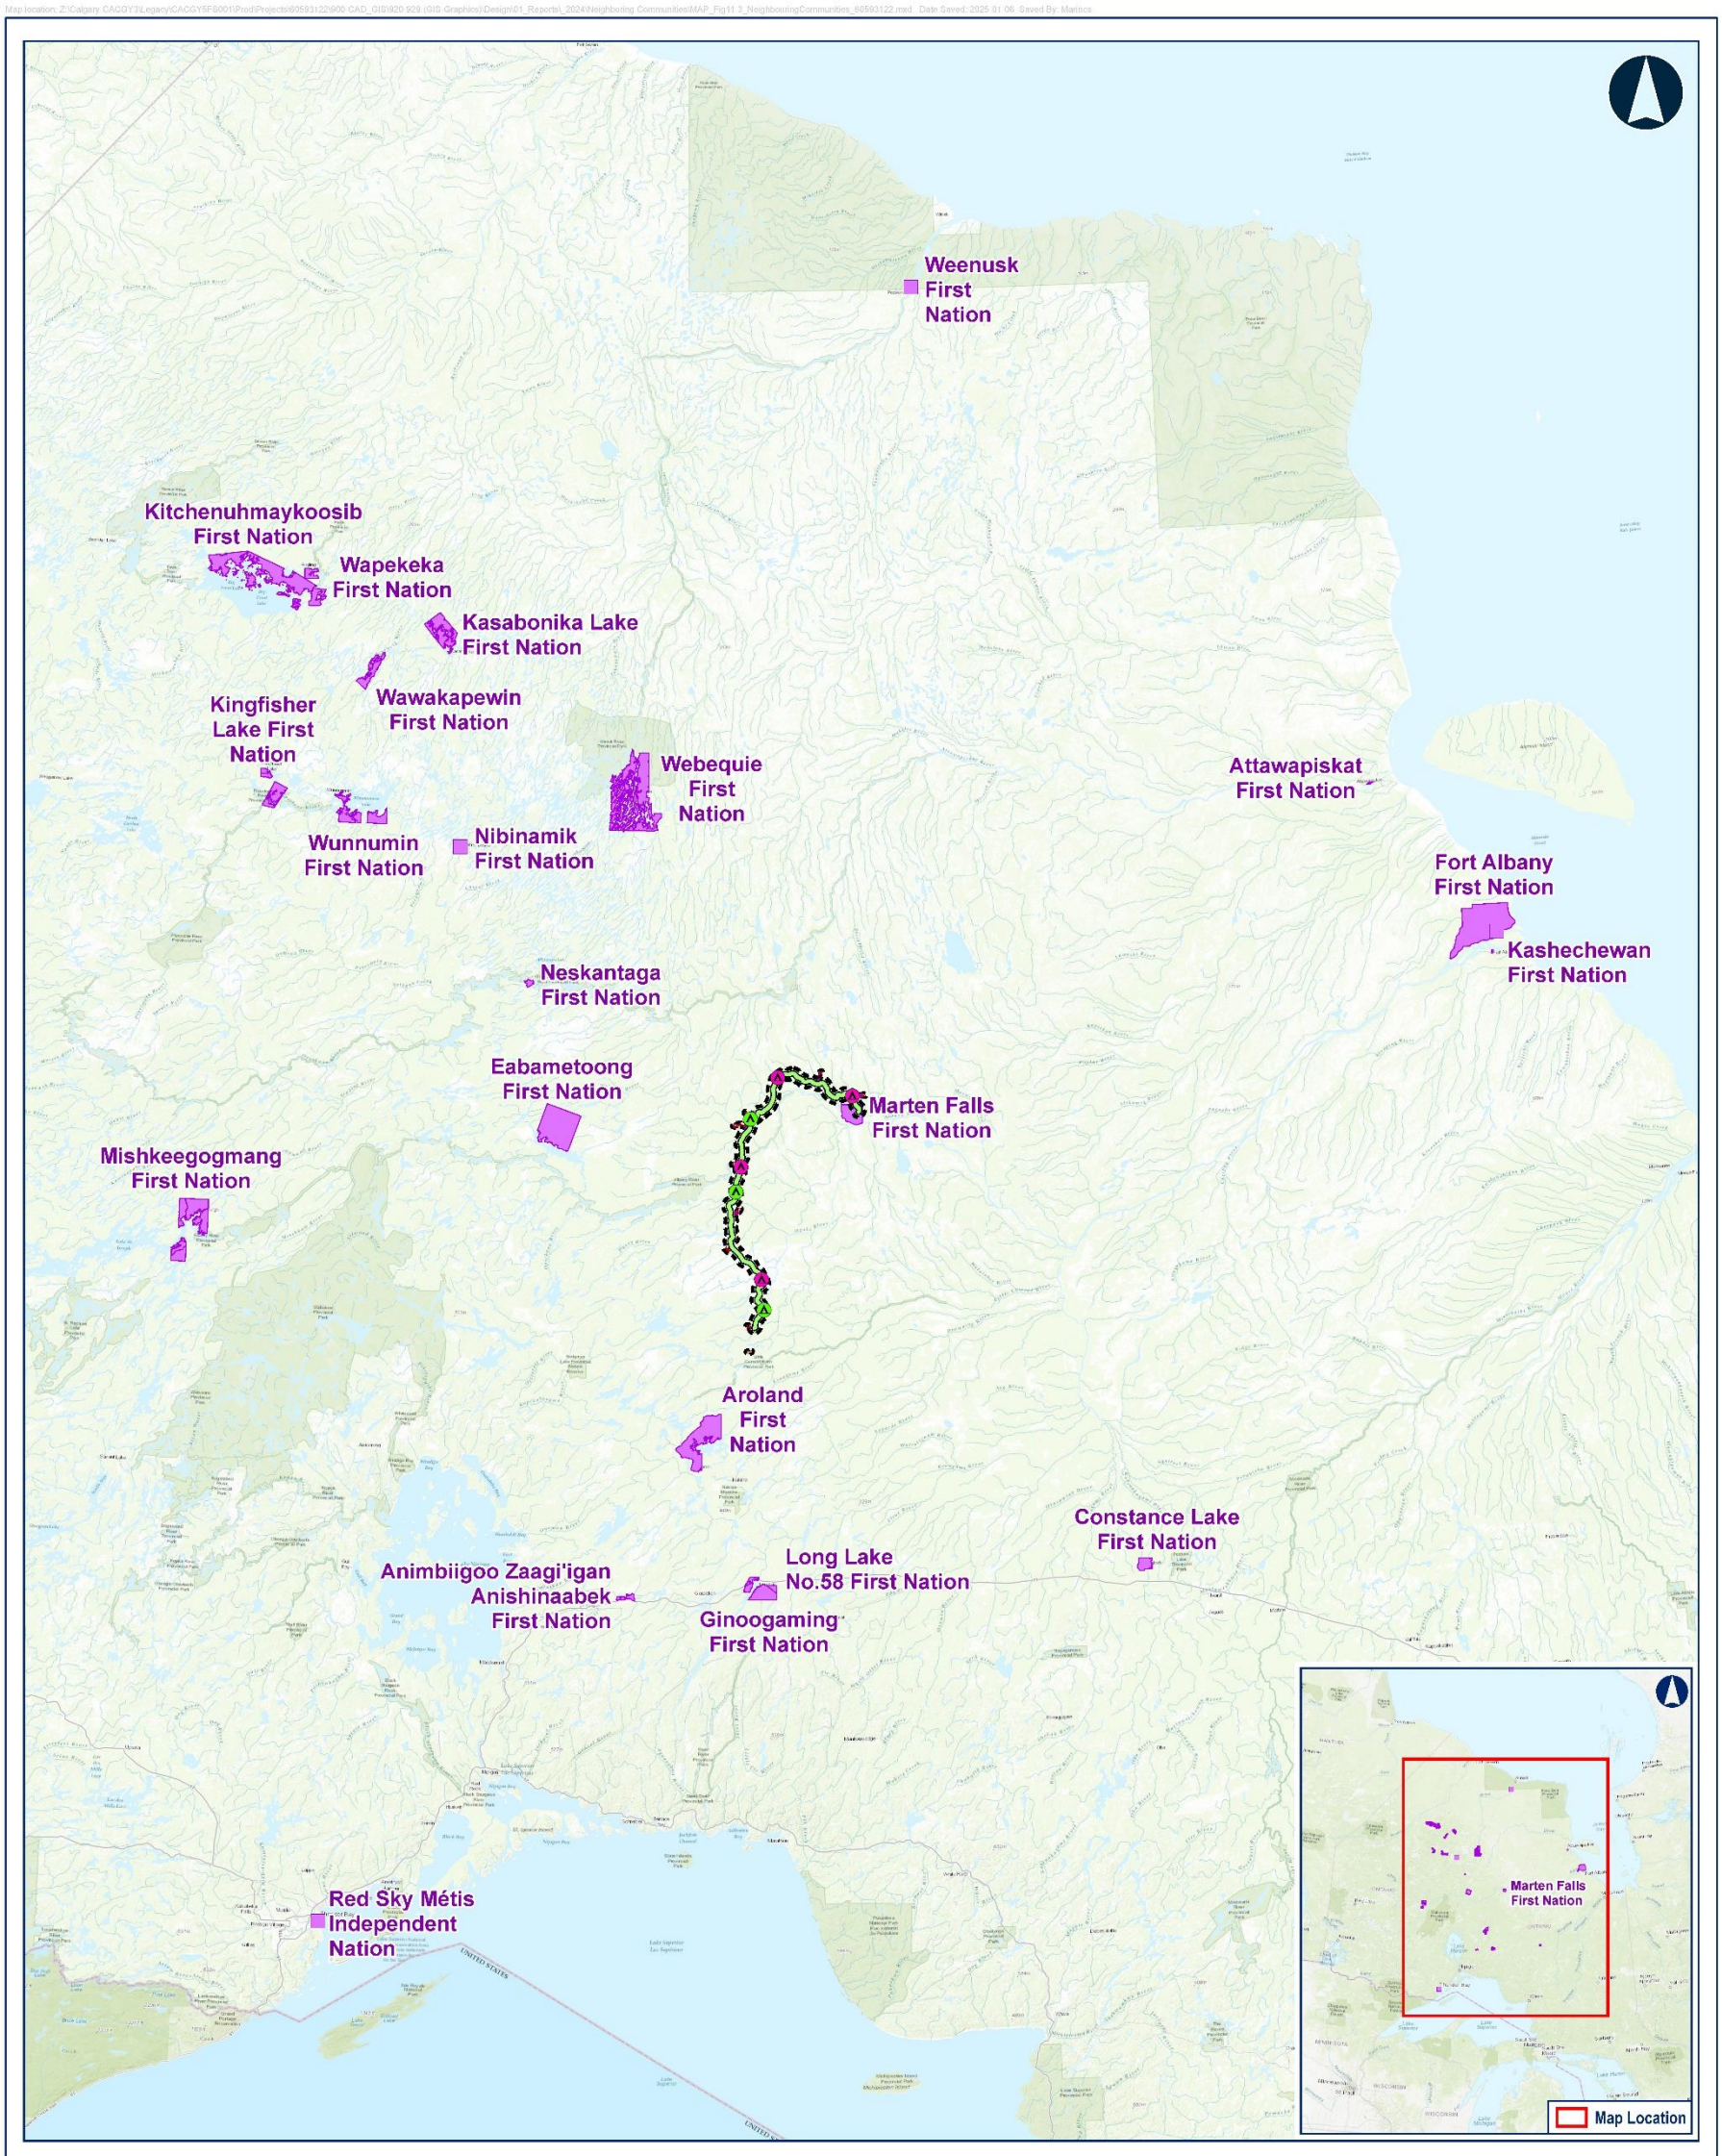
Marten Falls First Nation's early and continuous involvement provided valuable insights on various aspects of the Community Access Road, including the Assessment Process, the Indigenous Knowledge Program, and the funding mechanisms offered to neighbouring Indigenous communities. Their involvement also led to tangible outcomes, including refinement of the Preferred Route and formal Band Council Resolutions supporting both the Preferred Route and submission of the Final Environmental Assessment / Impact Statement.

Marten Falls First Nation's participation has helped ensure that traditional knowledge and practices are incorporated into the Assessment Process. As the Proponent and key rightsholder, Marten Falls First Nation is most directly impacted by the outcome of the Community Access Road, fostering a deeper level of engagement and commitment to the Community Access Road's success.

11.3.2 Neighbouring Indigenous Communities

The term "neighbouring" is used to identify any Indigenous community being consulted and engaged with respect to the Community Access Road; the term is not in reference to proximity. Marten Falls First Nation is regarded as both the Proponent and the most potentially impacted community; and participates in consultation and engagement activities for neighbouring Indigenous communities.

Table 11-1 lists the neighbouring Indigenous communities, as identified by the Ministry of the Environment, Conservation and Parks (A. Cross, 2018, personal communication), to be consulted based on their constitutionally protected Aboriginal and / or Treaty Rights that may be adversely affected by the Community Access Road, or who may be interested in the Community Access Road. This list was later identified in the Marten Falls-Ontario Memorandum of Understanding on Shared Consultation Responsibilities in 2020, and then later updated to include Long Lake #58 First Nation on a rights basis (L. Churchill, 2020, personal communication). Neighbouring Indigenous communities are official representatives of an Indigenous community as opposed to interested community members, who are categorized as interested persons.



The list of neighbouring Indigenous communities also includes communities listed in the Agency's Preliminary List of Indigenous Communities for Proponent Engagement on the Marten Falls Access Road, with the addition of Mishkeegogamang First Nation; this was the only additional community on the Agency's list that was not on the Ministry of the Environment, Conservation and Parks' list.

Table 11-1: Indigenous Communities and their Affiliations

Tribal Council Affiliation	Community or Organization
Matawa First Nations Management (Nishnawbe Aski Nation)	• Marten Falls First Nation (Proponent and potentially affected Indigenous community) • Aroland First Nation • Constance Lake First Nation • Eabametoong First Nation (Fort Hope) • Ginoogaming First Nation • Neskantaga First Nation • Nibinamik First Nation • Webequie First Nation
Matawa First Nation and the Union of Ontario Indians (Nishnawbe Aski Nation)	• Long Lake #58 First Nation
Mushkegowuk Council (Nishnawbe Aski Nation)	• Attawapiskat First Nation • Fort Albany First Nation • Kashechewan First Nation
Shibogama First Nations Council (Nishnawbe Aski Nation)	• Kasabonika Lake First Nation • Kingfisher Lake First Nation • Wapekeka First Nation • Wawakapewin First Nation • Wunnumin Lake First Nation
Independent First Nations Alliance	• Kitchenuhmaykoosib Inninuwug First Nation
Independent First Nations (Nishnawbe Aski Nation)	• Mishkeegogamang First Nation • Weenusk First Nation
Nokiiwin Tribal Council	• Animbiigoo Zaagi'igan Anishinaabek
Métis Nation of Ontario (For the purpose of engagement on the Community Access Road, it was advised by Métis Nation of Ontario in December 2023 to combine engagement and communication with Métis Nation of Ontario, Greenstone Métis Council, and Métis Nation of Ontario Region 2 under the name of Métis Nation of Ontario in the record of consultation. This merge was requested to reduce duplications for staff and occurred in December 2024).	• Métis Nation of Ontario, Region 2 and Greenstone Métis Council
Independent Métis Nation	• Red Sky Métis Independent Nation

Figure 11-2 shows the location of neighbouring Indigenous communities in proximity to the Community Access Road.

Figure 11-2: Location of Neighbouring Indigenous Communities

To help achieve an appropriate level of consultation and engagement related to the Community Access Road (in terms of frequency and depth), the list of communities being engaged was evaluated based on the following criteria:

- Expressed interest (to date) in the Community Access Road, including applying to Ministry of Energy and Mines, and the Agency for capacity funding;
- Aboriginal and / or Treaty Rights, including any rights that neighbouring Indigenous communities themselves have identified, that may be adversely affected by the Community Access Road;
- Geographical distance or proximity to the study area;
- Located downstream of the Community Access Road, with the potential to experience effects on watercourses due the Community Access Road;
- Traditional and / or current land use within the study area or of lands potentially affected by the Community Access Road;
- Potential for effects on the environmental and community well-being (social, economics, and human health conditions) of neighbouring Indigenous communities; and
- Provided comments during the Assessment Process.

Throughout the Assessment Process, Marten Falls First Nation adjusted its approach to engaging with each Indigenous community based on these criteria, evolving the list as new information became available and additional neighbouring Indigenous communities engaged in the consultation and engagement opportunities.

The above criteria were also used to identify which communities were offered funding to participate in the Indigenous Knowledge Program and the Community Capacity Funding Program[2] (formerly known as the Community Coordinator Program). A description of the Indigenous Knowledge Program and the Community Coordinator Program / Community Capacity Funding Program is provided in **Sections 11.3.3** and **11.3.4**, respectively.

2. To better serve the interest of Indigenous communities in reviewing the Draft Environmental Assessment / Impact Statement, the Community Coordinator Program was replaced with the Community Capacity Funding Program in November 2024.

11.3.3 Indigenous Knowledge Program

In December 2019, the Project Team introduced the Indigenous Knowledge Program. An important part of the Assessment Process is collecting Indigenous Knowledge and information on Indigenous land and resource use to help understand existing conditions and predict the potential effects of the Community Access Road, including impacts to Aboriginal and / or Treaty Rights and Interests. To honour and respect Indigenous Knowledge, a Sharing Agreement was developed with each community that chose to participate in the program. The agreements outlined how confidential and sensitive information will be protected and inform the Assessment Process.

Funding to participate in the Indigenous Knowledge Program was also provided, with six Indigenous communities receiving funding to date and one additional community currently in the process of receiving funding. As of September 5, 2025, Indigenous Knowledge was received from Marten Falls First Nation, Animbiigoo-Zaagi'igan Anishinaabek, Aroland First Nation, Fort Albany First Nation, Ginoogaming First Nation, Kashechewan First Nation, and Weenusk First Nation. For a summary of those who participated in the Indigenous Knowledge Program and / or received funding to do so (by September 5, 2025), refer to **Table 11-2**.

Communities who expressed interest, or did not respond to outreach, continued to be encouraged to participate in the Indigenous Knowledge Program through regular outreach and offering of funding; this encouragement continued throughout the Assessment Process. Alternative methods of consultation were also offered to communities who declined to participate in the Indigenous Knowledge Program. For example, opportunities to meet with the Marten Falls First Nation Project Team or funding through the Community Coordinator Program / Community Capacity Funding Program.

11.3.4 Community Coordinator Program / Community Capacity Funding Program

A Community Coordinator Program, with funding, was developed to support the participation of specific Indigenous communities in consultation and engagement activities for the Community Access Road. This program, which started in April 2022, was designed to assist communities participate in the Assessment Process in ways that worked best for each community. It was expected that the program would continue until the submission of the Final Environmental Assessment / Impact Statement. Refer to **Section 11.3.2** for a list of criteria used to determine eligibility.

Community Coordinators were envisioned to support Community Access Road consultation and engagement activities, meetings, and events by helping collect input from community members to share with the Project Team for inclusion in the Assessment Process.

Since the start of the program, Marten Falls First Nation has had two Community Coordinators; one former and one current, with a period during which their responsibilities overlapped. Communications and meetings with other communities regarding their interest in participating continued until the program ended in October 2024; at that time no other neighbouring Indigenous communities had chosen to participate.

Due to limited uptake, the Community Coordinator Program was reimagined as the Community Capacity Funding Program. It was introduced in November 2024 to offer flexible funding to support communities in reviewing the Draft Environmental Assessment / Impact Statement, and participating in consultation and engagement activities. This one-time capacity funding payment was designed to support engagement in the Community Access Road in a way that best suited the unique needs of each eligible Indigenous community.

The timing of the shift in funding programs coincided with preparations for release of the Draft Environmental Assessment / Impact Statement. Considering the importance of gaining Indigenous communities' feedback on the Draft, the Project Team provided financial support to assist with this review. This new approach provided communities the flexibility and autonomy to allocate funds as needed.

As of September 5, 2025, nine communities had been provided with Community Capacity Funding. For a summary of those who participated in either the Community Coordinator Program or the Community Capacity Funding (by September 5, 2025), refer to **Table 11-2**. Of note, Eabametoong First Nation and Long Lake #58 First Nation had also expressed interest in Community Capacity Funding but had not yet advanced the steps necessary to obtain funding (for example, signing the funding agreement or providing banking information).

This redirected approach resulted in more capacity for participation in consultation and engagement for the Community Access Road. During the timeline of the Community Coordinator Program, only one community participated, whereas nine communities received Community Capacity Funding and all those who received funding provided feedback on the Draft Environmental Assessment / Impact Statement (as of September 5, 2025), with the exception of the Proponent, Marten Falls First Nation.

Table 11-2: Status of Neighbouring Indigenous Communities' Participation in the Community Capacity Funding Program and the Indigenous Knowledge Program

No.	Indigenous Community	Status of Uptake in Community Capacity Funding Program and Comments on the Draft Environmental Assessment / Impact Statement	Status of Uptake for Community Coordinator Program	Status of Funding Offer for Indigenous Knowledge Program
1	Aroland First Nation	• Funding provided • Aroland First Nation provided comments on the Draft Environmental Assessment / Impact Statement	• Aroland First Nation was reviewing applicants for the position • The Community Coordinator Program was amended to the Community Capacity Funding Program in advance of an applicant being selected by the community	• Funding Provided • Received Indigenous Knowledge from the community
2	Attawapiskat First Nation	• Capacity Funding information sent to community • No response received • Attawapiskat First Nation provided comments on the Draft Environmental Assessment / Impact Statement	• Offered • No response received	• Indicated they do not want to participate in the Indigenous Knowledge Program
3	Animbiigoo-Zaagi'igan Anishinaabek	• Funding provided • Animbiigoo-Zaagi'igan Anishinaabek provided comments on the Draft Environmental Assessment / Impact Statement	• Offered • No response received	• Funding provided • Received Indigenous Knowledge from the community
4	Constance Lake First Nation	• Funding provided • Contance Lake First Nation provided comments on the Draft Environmental Assessment / Impact Statement	• Offered • Expressed interest; noted difficulty finding resource to fill role • The Community Coordinator Program was amended to the Community Capacity Funding Program in advance of an applicant being selected by the community	• The Sharing Agreement is with the community for signing • The updated funding agreement is with the community for review • Constance Lake First Nation did not provide Indigenous Knowledge
5	Eabametoong First Nation	• Community Capacity Funding information sent to community • Community acknowledged receipt of information and expressed interest. Follow-ups have been sent; no further response received regarding the program during the Assessment Process • Eabametoong First Nation provided comments on the Draft Environmental Assessment / Impact Statement, after the review period ended	• Offered • No response received	• Updated versions of the sharing and funding agreements are with the community for review • Eabamatoong First Nation did not provide Indigenous Knowledge
6	Fort Albany First Nation	• Funding provided • Fort Albany First Nation provided comments on the Draft Environmental Assessment / Impact Statement	• Offered • Acknowledged offer • The Community Coordinator Program was amended to the Community Capacity Funding Program in advance of an applicant being selected by the community	• Funding provided • Received Indigenous Knowledge from the community
7	Ginoogaming First Nation	• Funding provided • Ginoogaming First Nation provided comments on the Draft Environmental Assessment / Impact Statement	• Offered • Have expressed interest in program; actively recruiting • The Community Coordinator Program was amended to the Community Capacity Funding Program in advance of an applicant being selected by the community	• Funding provided • Received Indigenous Knowledge from the community
8	Kasabonika Lake First Nation	• Community Capacity Funding information sent to community • No response received • Kasabonika Lake First Nation did not provide comments on the Draft Environmental Assessment / Impact Statement	• Offered • No response received	• Updated versions of the sharing and funding agreements are with the community for review • Kasabonika Lake First Nation did not provide Indigenous Knowledge

No.	Indigenous Community	Status of Uptake in Community Capacity Funding Program and Comments on the Draft Environmental Assessment / Impact Statement	Status of Uptake for Community Coordinator Program	Status of Funding Offer for Indigenous Knowledge Program
9	Kashechewan First Nation	• Funding provided • Kashechewan First Nation provided comments on the Draft Environmental Assessment / Impact Statement	• Offered • Acknowledged offer • The Community Coordinator Program was amended to the Community Capacity Funding Program in advance of an applicant being selected by the community	• Funding provided • Received Indigenous Knowledge from the community
10	Long Lake #58 First Nation	• Community Capacity Funding information sent to community • Community acknowledged receipt of information and expressed interest; Community Capacity Funding Agreement has been sent to the community • Long Lake #58 First Nation did not provide comments on the Draft Environmental Assessment / Impact Statement	• Offered • Acknowledged offer • The Community Coordinator Program was amended to the Community Capacity Funding Program in advance of an applicant being selected by the community	• Initial versions of sharing and funding agreements sent to the community • Long Lake #58 First Nation did not provide Indigenous Knowledge
11	Marten Falls First Nation	• Funding provided • Marten Falls First Nation did not provide comments on the Draft Environmental Assessment / Impact Statement	• One previous Community Coordinator hired (living in Marten Falls); one current Community Coordinator (living outside of Marten Falls) • Funding provided	• Funding provided • Received Indigenous Knowledge from the Community
12	Neskantaga First Nation	• Community Capacity Funding information sent to community • No response received • Neskantaga First Nation did not provide comments on the Draft Environmental Assessment / Impact Statement	• Offered • No response received	• Updated versions of the sharing and funding agreements are with the community for review • Neskantaga First Nation did not provide Indigenous Knowledge
13	Nibinamik First Nation	• Funding provided • Nibinamik First Nation provided comments on the Draft Environmental Assessment / Impact Statement	• Offered • No response received	• Initial versions of the sharing and funding agreements sent to the community • Nibinamik First Nation did not provide Indigenous Knowledge
14	Webequie First Nation	• Community Capacity Funding information sent to community • No response received • Webequie First Nation did not provide comments on the Draft Environmental Assessment / Impact Statement	• Offered • No response received	• Updated versions of the sharing and funding agreements are with the community for review • Webequie First Nation did not provide Indigenous Knowledge
15	Weenusk First Nation	• Funding provided • Weenusk First Nation provided comments on the Draft Environmental Assessment / Impact Statement	• Offered • Acknowledged offer • The Community Coordinator Program was amended to the Community Capacity Funding Program in advance of an applicant being selected by the community	• The final versions of the sharing and funding agreements have been signed by the Project Team and the community • Once banking information is shared by Weenusk First Nation, funding for Indigenous Knowledge will be provided to Weenusk First Nation • Received Indigenous Knowledge from the community

Ongoing outreach continued for communities who did not respond; this encouragement continued throughout the Assessment Process. Alternative methods of consultation were also offered to communities who declined to participate (for example, opportunities to meet with the Project Team).

The Record of Consultation and Engagement for Indigenous Communities is available in **Appendix X** with additional information.

11.3.5 Interested Persons

Interested persons are defined as individuals and groups (for example, associations, non-governmental organizations, industry, and academia) who could have an interest in the Community Access Road. This includes, but is not limited to, communities in the region, those with commercial interests in the area (for example, forestry, trappers, outfitters, and other mineral tenure holders), and recreational users (for example, campers, hunters, and environmental groups). Interested persons also include individual members of an Indigenous community who are interested in the Community Access Road, as opposed to official representatives of an Indigenous community.

Marten Falls First Nation has consulted and engaged with members of the public, as listed in the Public Participation Plan for the Marten Falls Community Access Road (Impact Assessment Agency of Canada, 2020c), with the following exceptions:

- Anishinabek Nation asked to be removed from the contact list in 2023; and
- Noront Resources Ltd. was removed from the contact list in 2023 following updates from the provincial government. Noront Resources Ltd. was renamed to Ring of Fire Metals and has been re-added to the contact list.

Members of the public and anyone interested in the Community Access Road have been able to join the contact list to receive frequent updates.

Section 11.7.3 provides a complete list of consultation and engagement activities for interested persons. **Section 11.7.3.4** summarizes key input received from interested persons and how it has been considered. Additionally, the Record of Consultation and Engagement for Interested Persons is available in **Appendix X**.

11.3.6 Crown Government Agencies and Municipalities

11.3.6.1 Federal and Provincial Agencies

Throughout the Assessment Process, constructive dialogues were established with various Crown government agencies. These agencies provided critical input, particularly

on environmental, cultural, social, and economic aspects of the Community Access Road. Their feedback has been instrumental in shaping the approach to the Community Access Road and ensuring compliance with regulatory frameworks. The following Crown government agencies were engaged:

- Canada Energy Regulator;
- Canadian Forest Service;
- Crown-Indigenous Relations and Northern Affairs Canada;
- Department of Fisheries and Oceans Canada;
- Employment and Social Development Canada;
- Environment and Climate Change Canada;
- Health Canada;
- Impact Assessment Agency of Canada;
- Indigenous and Northern Affairs Canada;
- Indigenous Services Canada;
- Infrastructure Canada;
- Infrastructure Ontario;
- Innovation, Science and Economic Development Canada;
- Natural Resources Canada;
- Nav Canada;
- Ontario Ministry of Citizenship and Multiculturalism;
- Ontario Ministry of Economic Development, Job Creation and Trade;
- Ontario Ministry of Finance;
- Ontario Ministry of Indigenous Affairs and First Nations Economic Development;
- Ontario Ministry of Mines;
- Ontario Ministry of Municipal Affairs and Housing;
- Ontario Ministry of Natural Resources;
- Ontario Ministry of Northern Development;
- Ontario Ministry of the Environment, Conservation and Parks;
- Ontario Ministry of the Solicitor General;
- Ontario Ministry of Tourism, Culture and Gaming;
- Ontario Ministry of Transportation;
- Ontario Parks;
- Transport Canada; and
- Treasury Board of Canada Secretariat.

Table 11-7 provides a list of consultation and engagement activities conducted between October 29, 2021, and September 5, 2025, with government agencies. **Section 11.7.4** summarizes key input received from government agencies and how it has been considered.

11.3.6.2 Municipalities

Municipalities were engaged to help ensure local concerns and perspectives were adequately represented. This engagement helped the Project Team be aware of local development plans and community needs. The following municipalities and groups representing municipal interests were included:

- Municipality of Sioux Lookout;
- Kenora District Services Board;
- Municipality of Greenstone;
- District of Thunder Bay Social Services Administration Board;
- Cochrane District Social Services Administration Board;
- City of Thunder Bay; and
- The Corporation of the City of Timmins.

Table 11-7 provides a list of consultation and engagement activities conducted between October 29, 2021, and September 5, 2025, with municipalities (under the government agencies column). **Section 11.7.4** summarizes key input received from municipalities and how it has been considered.

Additionally, the Record of Consultation and Engagement for Government Agencies is available in **Appendix X**.

11.4 Consultation and Engagement Milestones, Input, and Timing

Consultation and engagement at each milestone were designed to receive feedback on targeted input before advancing to the next stage of the Assessment Process. **Table 11-3** outlines each milestone, its timing, and the targeted input and feedback requested.

Table 11-3: Milestones, Input, and Timing

Milestone	Targeted Input	Timing
Milestone 1: Notice of Commencement of Environmental Assessment	• Requested information to determine and identify: – Level of interest in the Community Access Road; – Level of interest in meetings / discussions with Chiefs and Councils and / or Indigenous communities; – How Indigenous communities would like to be kept informed during the Assessment Process; and – Level of interest in creating Indigenous community-specific consultation and engagement plan(s) as they relate to the Assessment Process.	October 29, 2021, to June 30, 2022
Milestone 2: Effects Assessment Methods	• Obtained feedback on: – Consultation and engagement approach; – Planned existing conditions field programs; – Existing conditions and results of field programs completed; – The Assessment Process; – Local and regional study areas, Community Access Road phases, criteria and indicators, interactions between the Community Access Road and the environment, and net effects characteristics; • Requested information to identify: – Indigenous community values and topics of interest; – Potential effects and impact management measures; – Effects of the Community Access Road on Aboriginal or Treaty Rights and potential impact management measures to avoid, mitigate, and offset effects; • Confirmed, through early release of community-specific Progress Report 1 for consultation and engagement, whether input and feedback provided during the previous milestone was captured appropriately; and • Shared an explainer video on cumulative effects on the Community Access Road website and notified via the October 2022 Community Access Road Newsletter.	July 1, 2022, to May 31, 2023
Milestone 3: Identification of Preferred Alternatives	• Obtained feedback on alternative routes: – Proposed mitigation measures; – Categories (for example, natural / physical, social, economic, and cultural) and technical / cost aspects that were considered in the route selection; – High-level comparative analysis of the potential net effect between the alternatives; – Results of the comparative analysis of advantages and disadvantages; – Preferred Route selected; – Preliminary road design, to the extent available; • Cumulative effects assessment methodology and Project Inclusions List requested information to identify: – Potential follow-up program measures including monitoring measures and adaptive management; – Potential projects and activities that could act cumulatively with the Community Access Road; – How Indigenous communities can participate in the Community Access Road; – Potential cumulative effects to be considered; and • Confirmed through early release of community-specific Progress Report 2 for consultation and engagement whether input and feedback provided during the previous milestone was captured appropriately.	June 1, 2023, to July 31, 2024
Milestone 4: Review of Draft Environmental Assessment / Impact Statement	• Obtained feedback on: – Ongoing issues resolution during the environmental assessment milestone; – Draft Environmental Assessment / Impact Statement; – Proposed impact management measures and follow-up program measures, including monitoring; – Measures and adaptive management plan(s); – Cumulative effects assessment results; – Draft Environmental Assessment / Impact Statement conclusions; and • Confirmed through early release of community-specific Progress Report 3 for consultation and engagement, the Draft Record of Consultation and Engagement for Interested Persons, and the Draft Environmental Assessment / Impact Statement) whether input and feedback provided during the previous milestone was captured appropriately.	August 1, 2024, to September 5, 2025
Milestone 5: Review of Final Environmental Assessment / Impact Statement	• Confirm through release of the last Progress Report (4) for Indigenous communities whether input and feedback provided during the previous milestone was captured appropriately. • Review the Final Environmental Assessment / Impact Statement (not part of this consultation and engagement reporting time period).	September 6, 2025, to February 20, 2026, (Proponent-led consultation and engagement ended February 20, 2026, with the initiation of regulator consultation and engagement February 20, 2026).

As noted in **Table 11-3**, Proponent-led consultation and engagement officially ends with the submission of the Final Environmental Assessment / Impact Statement to the regulators. Consultation and engagement during the review of the Final Environmental Assessment / Impact Statement is undertaken by the federal and provincial government agencies. The Proponent, however, will support the regulator's review process as necessary up until the regulators' decision is made (for example, provide responses to comments, attend meetings as requested).

11.5 How We Engaged

Consultation and engagement for the Community Access Road involved a range of methods and communication channels applied throughout Milestones 1, 2, 3, and 4. These methods supported consistent sharing of information, opportunities for consultation and engagement, and the collection of feedback from Indigenous communities, government agencies, and interested persons.

Section 11.5 describes the broader consultation and engagement activities used to communicate and engage with audiences interested in the Community Access Road, including Indigenous communities, interested persons, and government agencies. Those described below, however, are only a subset of the outreach conducted throughout the Assessment Process. Consultation and engagement was also specifically tailored to meet the unique needs of those being engaged. For example, provincially-supported events—like the Three-Road Project Expo and Gathering and the Aboriginal and / or Treaty Rights and Interests Forum—offered a space for Indigenous communities to gather over several days to collect information and discuss their values and interests. In addition, Indigenous communities were encouraged to meet with the Project Team throughout the Assessment Process; **Table 11-7** provides a summary of the meetings held and **Section 11.7.2** provides more information on those activities tailored for Indigenous communities.

Table 11-7 provides an overview of activities undertaken through Milestones 1, 2, 3, and 4. Communication and engagement activities that were tailored to a specific audience are summarized in **Section 11.7**. Detailed descriptions of all activities listed below are available in **Appendix X,** the Record of Consultation and Engagement, including detailed records of meetings, correspondence, notices, and participation.

11.5.1 Notice of Commencement of Environmental Assessment

On October 29, 2021, the Notice of Commencement of Environmental Assessment was circulated to Marten Falls First Nation, neighbouring Indigenous communities, government agencies, and interested persons, including individuals or groups that are potentially affected by the Community Access Road and / or have an interest in the Community Access Road.

The Notice of Commencement of Environmental Assessment was circulated via email on October 29, 2021, to individuals and groups on the contact list; this list was kept up-to-date throughout the Assessment Process. Notices were also distributed via mail and fax on November 1, 2021. Additionally, radio and newspaper advertisements were also placed.

The Notice of Commencement of Environmental Assessment was also made available on the Project website in English, French, Ojibway, Oji-Cree, and Cree.

11.5.2 Website

The Community Access Road website was developed to provide ongoing access to information about the Project and planned consultation and engagement activities; consideration was given to allow users with low bandwidth and slow internet connection to easily access information. The website was continuously updated throughout the Assessment Process and information was published at key milestones. Examples of posted information include frequently asked questions, Assessment Process information and timelines, videos and webinar recordings, news stories, information on the Indigenous Knowledge Program; and existing publicly available documentation and reports (including the Draft Environmental Assessment / Impact Statement, summary reports, field notices). A contact page was also available for anyone to submit questions, comments, or concerns. The website also reflected information that had been shared via the E-blasts and social media accounts.

11.5.3 Social Media

The Community Access Road social media accounts (Facebook, Instagram, and LinkedIn) were used to share ongoing updates about the Community Access Road and upcoming consultation and engagement activities. Regular posts were shared that provided information on field updates, E-blasts, videos and webinars, Public Information Centres, and information on reports, including the Draft Environmental Assessment /

Impact Statement. Social media content reinforced information shared through the website and E-blasts, helping ensure updates were accessible to a wide audience.

11.5.4 Monthly E-Blasts

Throughout the Assessment Process, newsletters (also known as E-blasts) were distributed via email to the approximately 600 people identified on the contact list. E-blasts were distributed monthly and included Community Access Road updates relevant to the month of distribution (for example, upcoming field programs, report distributions, and engagement activities). Links to the Community Access Road's social media pages and contact information were included. Additionally, E-blasts were published on the Community Access Road website, receiving over 9,596 views.

11.5.5 Field Program Notifications

To help understand the field programs related to valued components, field notices were distributed with plain language information about what the Project Team is studying, why it is important, when the field programs are taking place, and what to expect when crews were in the field (for example, an increase in air traffic as crews travel by helicopter). Field notices encouraged recipients to contact the Project Team if they had any questions or comments. Typically, discussion guides were distributed in advance of field notices with key questions to help shape programs (including timing and locations); however, some field programs required quick mobilization (such as winter programs dependent on snowfall) and discussion guides were distributed at the same time as field notices. Notices were distributed via email to persons identified on the contact list prior to the relevant field program taking place.

11.5.6 Discussion Guides

Discussion guides for various field programs were shared with the Community Access Road contact list prior to the commencement of field programs. These guides provided an overview of the upcoming field program, solicited feedback on key questions listed in the guide, and encouraged interested individuals to book a meeting with the Project Team to discuss their questions and concerns, as well as their Aboriginal and / or Treaty Rights and Interests in the study area. The discussion guides received over 1,871 views. Insights shared by Indigenous communities and interested persons had the opportunity to help shape and enrich the field programs.

Typically, after the discussion guides were distributed and feedback was collected (if provided), a field notice was distributed with confirmed dates for the field programs. Additional information related to planned field programs was also included in the

monthly E-blasts and shared through social media. A web-based version, with an online survey, was also made available on the Community Access Road website.

11.5.7 Public Information Centres

Four Public Information Centres were held throughout Milestones 1, 2, 3, and 4. Note that Public Information Centre #1 and #2 were part of the Terms of Reference so descriptions are therefore not included. A fifth Public Information Centre (Public Information Centre #7) was held outside of the reporting period and is summarized in **Section 11.811.9**.

A detailed description of Public Information Centres, including the materials presented, comments, questions, and responses (via summary report) is available in **Appendix X**, the Record of Consultation and Engagement for Interested Persons.

11.5.7.1 Public Information Centre #3

Notification: On June 13, 2022, a notice was circulated to the Marten Falls First Nation community, neighbouring Indigenous communities, government agencies, and interested persons regarding Public Information Centre #3. The notice was provided via both hard and electronic copies (for example, mail, email) and posted on the Community Access Road website on June 13, 2022, in English, French, Cree, Ojibway, and Oji-Cree. The notice was also published between June 14 and 17, 2022, in various newspapers. Online advertisements were posted from June 13 to 27, 2022, through various media outlets. Radio advertisements were also released during the same period. Additionally, the Public Information Centre was advertised on the Community Access Road Facebook page and the private Marten Falls First Nation Facebook page.

Dates and Locations: June 27, 2022, in Thunder Bay and on June 29, 2022, in the Municipality of Greenstone (Geraldton).

Objectives and Topics: Public Information Centre #3 provided an update on the Community Access Road, including: updates since the Terms of Reference; the Assessment Process; study areas, including specific updates made to reflect potential sources of aggregate material and input received from Indigenous communities; preliminary results of field programs and information on upcoming field programs; overview and importance of Indigenous Knowledge and Aboriginal and / or Treaty Rights and Interests; how Indigenous communities have been involved to date and plans for future consultation and engagement; feedback heard to date and how it is being considered; ongoing and future consultation and engagement opportunities; and next steps.

Attendees: Approximately 33 individuals attended Public Information Centre #3; 25 attendees in Thunder Bay on June 27, 2022, and 8 attendees in Geraldton on June 29, 2022. Attendees included Indigenous community members, government agencies, members of the public / local residents, environmental groups, and industry representatives. Attendees (and members of the following groups) included:

- Marten Falls First Nation;
- Aroland First Nation;
- Ring of Fire Metals (formerly known as Noront Resources Ltd.);
- The BMI Group;
- Ministry of Energy and Mines;
- Mishkeegogamang First Nation;
- Ne-Daa-Kii-Me-Naan Inc. (Nedaak);
- Thunder Bay residents; and
- Geraldton residents.

One staff member from the Ministry of Energy and Mines was also present to provide a brief update and assist in answering questions.

11.5.7.2 Public Information Centre #4

Notification: A formal notice and invitation to Public Information Centre #4 was published on the Community Access Road website on November 22, 2022, in English, French, Cree, Ojibway, and Oji-Cree. The notice was published between November 22 and December 1, 2022, in various newspapers. Online advertisements were also posted / released through various media outlets between November 22 and December 9, 2022, and radio advertisements were released between November 28 to December 9, 2022, on various radio stations. Additionally, the Public Information Centre was advertised on the Community Access Road Facebook page and the private Marten Falls First Nation Facebook page.

Dates and Locations: December 7, 2022, in Thunder Bay and on December 8, 2022, in Geraldton.

Objectives and Topics: Public Information Centre #4 provided an update on the Community Access Road, including: an overview and updates since Public Information Centre #3, as well as what was heard and how feedback was considered; existing conditions results for completed studies; assessment of impacts and comparison of route alternatives; preliminary results of field programs and information on upcoming field programs; overview and importance of Indigenous Knowledge and Aboriginal and /

or Treaty Rights and Interests; process for identifying the preliminary technically preferred route and how route alternatives would be assessed, recommended and a Preferred Route chosen; and next steps.

Attendees: Approximately 46 individuals attended Public Information Centre #4; 30 attendees in Thunder Bay on December 7, 2022, and 16 attendees in Geraldton on December 8, 2022. Attendees included Indigenous community members, government agencies, members of the public / local residents, environmental groups, and industry representatives. Attendees (and members of the following groups) included:

- Marten Falls First Nation;
- Ring of Fire Metals;
- Mining Claim Holders;
- Thunder Bay News Watch;
- Lakehead University students;
- LTL Environmental;
- Métis Nation of Ontario;
- Greenstone Council;
- Thunder Bay residents; and
- Geraldton residents.

Staff from the Ministry of Energy and Mines as well as Ministry of Natural Resources were present to provide a brief update and assist in answering questions.

11.5.7.3 Public Information Centre #5

Notification: A formal notice and invitation to Public Information Centre #5 was published on the Community Access Road website on October 10, 2023, in English, French, Cree, Ojibway, and Oji-Cree. The notice was published between October 19 and 23, 2023, in various newspapers. Online advertisements were also posted / released through various media outlets between October 11 and October 26, 2023, and radio advertisements were released between October 11 and October 26, 2023. Additionally, the Public Information Centre was advertised on the Community Access Road Facebook and LinkedIn pages and the private Marten Falls First Nation Facebook page.

Dates and Locations: October 25, 2023, in Thunder Bay and on October 26, 2023, in Geraldton.

Objectives and Topics: Public Information Centre #5 provided an update on the Community Access Road, including: current stage of the process, as well as the different construction steps needed to build a road; what has happened since Public Information Centre #4, including what was heard and how feedback was considered; what was heard at the Aboriginal and / or Treaty Rights and Interests Forum in February 2023 and plans for the next forum; existing conditions results for completed studies; how Indigenous Knowledge was used and how it informed the process; preliminary technically Preferred Route recommendation, how route alternatives were assessed, recommended and a preliminary technically Preferred Route chosen; cumulative effects assessment, including why it is important and the Project Inclusions List; and next steps and future opportunities to get involved.

Attendees: Approximately 35 individuals attended Public Information Centre #5; 21 attendees in Thunder Bay on October 25, 2023, and 14 attendees in Geraldton on October 26, 2023. Attendees included Indigenous community members, government agencies, members of the public / local residents, environmental groups, and industry representatives. Attendees (and members of the following groups) included:

- Marten Falls First Nation;
- Eabametoong First Nation;
- South Gillis residents;
- Jellico residents;
- Thunder Bay residents;
- Geraldton residents;
- North Superior Workforce Planning;
- Outland / Horizon North;
- Far North District;
- Ministry of Natural resources and Forestry;
- Representative for Member of Provincial Parliament, Kevin Holland;
- Municipality of Greenstone; and
- Longlac-Greenstone Council.

11.5.7.4 Public Information Centre #6

Notice: A formal notice and invitation to Public Information Centre #6 was combined with the Notice of the Draft Environmental Assessment / Impact Statement and was published on the Community Access Road website on April 22, 2025, in English, French, Cree, Ojibway, and Oji-Cree. The notice was published between April 22 and

May 26, 2025, in various newspapers and radio stations. Additionally, the Public Information Centre was advertised on the Community Access Road Facebook, Instagram, and LinkedIn pages and the private Marten Falls First Nation Facebook page.

Dates and Locations: May 26, 2025, in Thunder Bay, and May 29, 2025, in Geraldton

Objectives and Topics: Public Information Centre #6 focused on the Draft Environmental Assessment / Impact Statement, community well-being, and cumulative effects. Information included: Draft Environmental Assessment / Impact Statement review process and schedule; ways to review and provide comments; feedback received to date; land and resource use; information on the Country Foods Program; potential effects and mitigations; cumulative effects process and results; final projects / activities considered as part of the Cumulative Effects Assessment; and, how the Community Access Road could affect community well-being for Marten Falls and nearby communities.

Attendees: Approximately 27 individuals attended Public Information Centre #6; 11 attendees in Thunder Bay on May 26, 2025, and 16 in Geraldton on May 29, 2025. Attendees included Indigenous community members, federal and provincial agencies, members of the public / local residents, environmental groups, and industry representatives. Attendees (and members of the following groups) included:

- Marten Falls First Nation members;
- Thunder Bay residents;
- Geraldton residents;
- Far North Resources Group;
- Four Rivers Environmental Services Group;
- Ministry of Natural Resources;
- Long Lake #58 First Nation members;
- Mushkegowuk Council;
- Municipality of Greenstone; and
- Longlac-Greenstone Council.

11.5.8 Webinars

Notifications for webinars were distributed via email to the contact list and posted on social media platforms including the Community Access Road Facebook page and the private Marten Falls First Nation and Ogoki Facebook page, on an as needed basis. Later in the Assessment Process, information was also posted to LinkedIn and

Instagram, starting November 2023 and March 2024, respectively. Notifications included the date and time of the webinar, links for registration, and webinar poster attachments. Reminder emails were sent shortly before the live webinar occurred.

11.5.8.1 Webinar Series 1: Valued Components

A total of 12 webinars were held in the first series, resulting in 40 questions and 279 views of the recordings. This first webinar series focused on sharing information about what was studied (also known as “valued components”), how and why. This included both Indigenous Knowledge and western science. **Table 11-4** outlines registration and attendance numbers, and recording views, for each webinar in the valued components series.

Table 11-4: Webinar Series 1 Details

Webinar Topic	Date	Engagement
Animals and Wildlife, Ungulates, and Furbearers	November 15, 2022	• 24 registered, 15 attended • 29 viewed the recording.
Surface Water, Fish and Fish Habitat	November 29, 2022	• 8 registered, 5 attended • 19 viewed the recording.

11.5.8.2 Webinar Series 2: Technical Webinars

Three technical webinars were held, resulting in 23 questions and 201 views of the recording. This series provided an ongoing opportunity for communication, dialogue,

and participation among Indigenous community members and other interested persons regarding the technical aspects and planning for the Community Access Road. The goal of the webinar series was to share information about the technical considerations of the road as part of the Assessment Process, offer participants the chance to learn about topics of interest, and create space for meaningful feedback. This approach was intended to broaden our audience, encourage engagement, and helped to ensure the feedback received informed and helped to strengthen the Assessment Process.

Additionally, a post-webinar survey for the climate change webinar was provided. Nine people completed the post-webinar survey on climate change adaptation.

Table 11-5 outlines registration and attendance numbers, and recording views, for each webinar in the technical webinar series.

Table 11-5: Webinar Series 2 Details

Webinar Topic	Date	Engagement
Route Selection	November 16, 2023	• 36 registered, 24 attended • 13 viewed the recording
Building the Community Access Road	November 26, 2024	• 57 registered, 31 attended • 97 viewed the recording
Climate Change Adaptation (including post-webinar survey)	February 8, 2024	• 40 registered, 26 attended • 91 viewed the recording.

11.5.8.3 Webinar Series 3: Draft Environmental Assessment / Impact Statement

Four webinars were held, resulting in 15 questions asked and 43 views of the recordings. The Draft Environmental Assessment / Impact Statement webinar series was developed as part of a broader suite of resources designed to support Indigenous communities and other interested individuals in reviewing the Draft Environmental Assessment / Impact Statement. The webinars explored key valued components across three major topic areas: land, water, and people and guided participants through the assessment approach used in each study. This included an overview of existing conditions, potential effects, proposed mitigation measures, and an examination of residual and cumulative effects. Overall, the webinars provided a high-level introduction to what could be explored in greater depth within the full Draft Environmental Assessment / Impact Statement. **Table 11-6** outlines registration and attendance numbers, and recording views, for each webinar in the Draft Environmental Assessment / Impact Statement series.

Table 11-6: Webinar Series 3 Details

Webinar Topic	Date	Engagement
Community Well-Being	May 6, 2025	• 23 registered, 17 attended • 14 viewed the recording
Land Valued Components: Ungulates (Atik / Caribou & Mooz / Moose)	May 15, 2025	• 13 registered, 8 attended • 5 viewed the recording
Water: Fish and Fish Habitat	May 22, 2025	• 22 registered, 11 attended • 1 viewed the recording
Land and Resource Use	June 5, 2025	• 19 registered, 13 attended • 23 viewed the recording

11.5.9 Videos

Videos were posted to the Community Access Road website and included in relevant E-blasts, on an as needed basis. Videos were also shared to the Community Access Road Facebook, Instagram, and LinkedIn pages to encourage broader outreach.

Valued Component Videos:

- Thirteen videos on valued components provided information about what is being studied and why, what has already been learned, and how individuals can get involved;
- The videos have received a total of 2,056 views and 130 downloads.

Draft Environmental Assessment / Impact Statement Videos:

- Four videos on the Environmental Assessment / Impact Assessment provided information about the federal and provincial processes, the Draft Environmental Assessment / Impact Statement, cumulative effects, Project effects and mitigations, what the Project Team has heard from Indigenous communities and interested persons, and how individuals can get involved;
- The videos have received a total of 527 views.

11.6 Draft Environmental Assessment / Impact Statement

The Draft Environmental Assessment / Impact Statement was released in stages to support review by Indigenous communities, interested persons, and government regulators. Early release for Indigenous communities began on February 18, 2025, initiating a 120-day review period. The public and regulator review period began later, on April 22, 2025, for a 60-day review period. The comment period for Indigenous

communities, interested persons, and government regulators was initially scheduled to conclude on June 23, 2025, but extension requests from Indigenous communities and government regulators resulted in the review period being extended to September 5, 2025.

To fulfill federal requirements, an Assessment Summary of the Draft Environmental Assessment / Impact Statement (with sufficient details for the reader to understand the Community Access Road) was included as part of the distribution package. To provide readers with easy access to the information they value most, the Assessment Summary consisted of the following components:

- Marten Falls First Nation Chief's letter;
- An Introduction to the Assessment Summary;
- Executive Summary of the Draft Environmental Assessment / Impact Statement;
- Frequently Asked Questions: Draft Environmental Assessment / Impact Statement;
- An Introduction to the Plain Language Summaries and Technical Supporting Documents;
- Eleven technical discipline plain language summaries;
- Map of the Preferred Route;
- Cumulative Effects Inclusions List; and
- USB drive that included all the components listed above, the Draft Environmental Assessment / Impact Statement, and the Technical Support Documents.

The Assessment Summary was available on the Community Access Road website, for viewing at Public Information Centre #6, and at specific public library locations.

Throughout the review period for the Draft Environmental Assessment / Impact Statement, the Project Team welcomed comments by email, telephone, or mail. A total of more than 1,900 comments were received on the Draft Environmental Assessment / Impact Statement. Of these, over 1,000 comments were submitted by 9 Indigenous communities: Aroland First Nation, Animbiigoo Zaagi'igan Anishinaabek, Constance Lake First Nation, Fort Albany First Nation, Ginoogaming First Nation, Kashechewan First Nation, Mushkegowuk Council, Nibinamik First Nation, and Weenusk First Nation.

In addition, Attawapiskat First Nation submitted comments to the Ministry of the Environment, Conservation and Parks and the Impact Assessment Agency of Canada, copying the Project Team.

Comments from interested persons totaled 10 submissions, including comments from Wildlife Conservation Society Canada, Andomoozwe Outfitters, Albany-Ogoki Outposts, and members of the public.

All comments and responses are included in the Feedback and Response Log (**Appendix C**), which documents each submission, the Project Team's response, and whether changes were made to the Final Environmental Assessment / Impact Statement.

11.7 Consultation and Engagement by Audience

11.7.1 Activities Snapshot

Table 11-7 provides an overview of consultation and engagement activities with Marten Falls First Nation, neighbouring Indigenous communities, and interested persons during the first four milestones: Notice of Commencement of Environmental Assessment; Effects Assessment Methods; Identification of Preferred Alternatives; and Review of Draft Environmental Assessment / Impact Statement.

A high-level summary of issues and feedback received through consultation and engagement activities during these milestones is included in **Section 11.7.2** (Indigenous communities), **Section 11.7.3** (interested persons), and **Section 11.7.4** (government agencies). The sections also demonstrate whether the information received informed milestones of the Assessment Process.

Section 11.9 provides a summary of consultation and engagement activities that took place after the fourth milestone and before submission of the Final Environmental Assessment / Impact Statement. **Section 11.10** provides a summary of consultation and engagement during and after the submission of the Final Environmental Assessment / Impact Statement.

Table 11-7: Consultation Snapshot – From October 29, 2021, to September 5, 2025

Activity	Description	Indigenous Communities	Interested Persons	Government Agencies
Notice of Commencement	• Distribution of the Notice of Commencement of Environmental Assessment (October 29, 2021).	Yes	Yes	Yes
Notice of Commencement	• Notice of Commencement Advertisement (October 29 to November 12, 2021).	Yes	Yes	Yes
Interim Record of Consultation and Engagement	• Draft Interim Record of Consultation and Engagement distributed to Indigenous communities for review (December 6, 2022).	Yes	Not applicable	Not applicable
Interim Record of Consultation and Engagement	• Email follow-up distributed in January 2023.	Yes	Not applicable	Not applicable
Progress Report 1	• Draft progress report distributed to Indigenous communities for review (December 6, 2022).	Yes	Not applicable	Not applicable
Progress Report 1	• Email follow-up distributed in January 2023.	Yes	Not applicable	Not applicable
Progress Report 2	• Draft progress report distributed to Indigenous communities for review (November 27, 2023).	Yes	Not applicable	Not applicable
Progress Report 2	• Email follow-up to request re-download of draft progress report (November 29, 2023).	Yes	Not applicable	Not applicable
Progress Report 3	• Draft progress report distributed to Indigenous communities for review (November 28, 2024).	Yes	Not applicable	Not applicable
Progress Report 3	• Email follow-up distributed in December 2024 and January 2025.	Yes	Not applicable	Not applicable
Draft Environmental Assessment / Impact Statement	• Release of the Draft Environmental Assessment / Impact Statement to Indigenous communities (February 18, 2025).	Yes	Not applicable	Not applicable
Draft Environmental Assessment / Impact Statement	• Email notification of the release of the Draft Environmental Assessment / Impact Statement to Indigenous communities (February 19, 2025).	Yes	Not applicable	Not applicable
Draft Environmental Assessment / Impact Statement	• Release of the Community Well-Being Report to Indigenous communities and email notification (April 10, 2025).	Yes	Not applicable	Not applicable
Draft Environmental Assessment / Impact Statement	• The Assessment Summary for the Draft Environmental Assessment / Impact Statement was distributed to Indigenous communities via Canada Post registered mail (February 19, 2025).	Yes	Not applicable	Not applicable
Draft Environmental Assessment / Impact Statement	• Notice of publication of the Draft Environmental Assessment / Impact Statement (April 22, 2025).	Yes	Yes	Yes
Draft Environmental Assessment / Impact Statement	• Release of the Draft Environmental Assessment / Impact Statement to interested persons and government agencies (April 22, 2025).	Yes	Yes	Yes
Draft Environmental Assessment / Impact Statement	• The Assessment Summary for the Draft Environmental Assessment / Impact Statement was made available online and at designated library locations (announcement made April 22, 2025).	Yes	Yes	Yes
Draft Environmental Assessment / Impact Statement	• Email follow-up reminder to provide feedback on the Draft Environmental Assessment / Impact Statement (June 19, 2025).	Yes	Yes	Yes
Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports	• Release of community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports (various dates between June and July 25).	Yes	Not applicable	Not applicable
Public Information Centres	• Public Information Centre #3 Notice distributed (June 13, 2022).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #3 in Thunder Bay (June 27, 2022).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #3 in Geraldton (June 29, 2022).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #4 Notice distributed (November 22, 2022).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #4 in Thunder Bay (December 7, 2022).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #4 in Geraldton (December 8, 2022).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #5 Notice distributed (October 10, 2023).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #5 in Thunder Bay (October 25, 2023).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #5 in Geraldton (October 26, 2023).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #6 Notice distributed (April 21, 2025).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #6 in Thunder Bay (May 26, 2025).	Yes	Yes	Yes
Public Information Centres	• Public Information Centre #6 in Geraldton (May 29, 2025).	Yes	Yes	Yes
Provincially-Supported Forums	• Aboriginal and / or Treaty Rights and Interests Forum #1 in Thunder Bay (February 8 and 9, 2023).	Yes	Not applicable	Yes
Provincially-Supported Forums	• Aboriginal and / or Treaty Rights and Interests Forum #2 in Thunder Bay (November 21 to 23, 2023).	Yes	Not applicable	Yes

Activity	Description	Indigenous Communities	Interested Persons	Government Agencies
Provincially-Supported Forums	• Three-Road Project Gathering and Expo in Thunder Bay (June 11 to June 13, 2024).	Yes	Not applicable	Yes
Provincially-Supported Forums	• Three-Road Project Gathering and Expo in Thunder Bay (February 19 to February 20, 2025).	Yes	Not Applicable	Yes
Provincially-Supported Forums	• Three-Road Project Gathering and Expo in Timmins (February 25 to February 26, 2025).	Yes	Not Applicable	Yes
Individual Community Access Road Meetings	• In-person meeting with Marten Falls First Nation to provide an update on the Community Access Road and the approval of the Terms of Reference (November 16 and 17, 2021).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person presentation to the Mushkegowuk Council Annual General Meeting (November 24, 2021).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Teleconference with Marten Falls First Nation to discuss the Assessment Process (February 2, 2022).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Teleconference with Métis Nation of Ontario to discuss the Indigenous Knowledge Program (February 4, 2022). • **Note:** also captured under the Indigenous Knowledge Program section below.	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Teleconference with Constance Lake First Nation (April 21, 2022). • **Note:** also captured under the Indigenous Knowledge Program and Community Coordinator Program sections below.	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Teleconference presentation to Mushkegowuk Tribal Council's Terrestrial Working Group (May 18, 2022).	Yes	Yes	Not applicable
Individual Community Access Road Meetings	• Teleconference with Marten Falls First Nation Senior Community Member Advisor to discuss and collect feedback on the upcoming Bird Field Program (May 31, 2022).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Marten Falls First Nation in advance of Public Information Centre #3 (June 28, 2022).	Yes	Yes	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Ginoogaming First Nation to discuss the Indigenous Knowledge Program and the Community Coordinator Program (July 5, 2022).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Long Lake #58 regarding Community Coordinator and Indigenous Knowledge Programs (August 9, 2022).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Marten Falls First Nation in advance of Public Information Centre #4 (November 2, 2022).	Yes	Yes	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Marten Falls First Nation in advance of Public Information Centre #4 (December 6, 2022).	Yes	Yes	Not applicable
Individual Community Access Road Meetings	• In-person Council-to-Council meeting with Marten Falls First Nation and Aroland First Nation in Thunder Bay. Meeting minutes were not taken (January 26, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Teleconference with Long Lake #58 First Nation to discuss the Community Coordinator Program and Indigenous Knowledge Program (February 13, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Ginoogaming First Nation to discuss the Indigenous Knowledge Program and the Community Coordinator Program (March 27, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Long Lake #58 First Nation, Constance Lake First Nation and Ginoogaming First Nation to discuss the Archaeology and Cultural Heritage reports (April 21, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Teleconference with Métis Nation of Ontario to discuss Archaeology and Cultural Heritage Program (April 27, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person Council-to-Council meeting with Eabametoong First Nation to provide an overview of the Community Access Road (May 10, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Marten Falls First Nation was held regarding the engineering, construction and the route selection process for the Community Access Road (May 15, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Long Lake #58 First Nation's legal counsel to discuss the Indigenous Knowledge Sharing Agreement (May 17, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Long Lake #58 First Nation was held to provide a Community Access Road overview (August 29, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Marten Falls First Nation in advance of Public Information Centre #5 (October 23, 2023).	Yes	Yes	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Marten Falls First Nation in advance of Public Information Centre #5 (October 24, 2023).	Yes	Yes	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Long Lake #58 First Nation Elders to discuss general updates for the Community Access Road (October 26, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Long Lake #58 First Nation was held as a follow-up to discuss the Community Coordinator and Indigenous Knowledge Programs meeting (November 10, 2023).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting held with Attawapiskat First Nation representatives to discuss the Community Access Road and Caribou Study Plan (December 4, 2023).	Yes	Not applicable	Not applicable

Activity	Description	Indigenous Communities	Interested Persons	Government Agencies
Individual Community Access Road Meetings	• In-person meeting with Nibinamik First Nation to provide a Community Access Road update (January 16, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Red Sky Métis Independent Nation to review the Draft Aboriginal and / or Treaty Rights and Interests Existing Conditions Report (March 19, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person Council-to-Council meeting with Aroland First Nation to build on and improve the relationship between the two nations and to provide both nations the opportunity to discuss any concerns or issues, including the previously drafted Communication Protocol Agreement (April 19, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person taskforce meeting between Marten Falls First Nation and Aroland First Nation (May 7, 2024). • **Note:** in April 2024, a taskforce was created between Marten Falls First Nation and Aroland First Nation to discuss various topics, including advancing discussions related to the Community Access Road and other road projects, as well as collaboration between the nations. Several taskforce meetings have occurred between the two communities; however, they are not specific to the Community Access Road and fall outside of the scope of this Environmental Assessment / Impact Statement.	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person taskforce meeting between Marten Falls First Nation and Aroland First Nation (May 28, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person Chief and Council meeting with Marten Falls First Nation to provide a Community Access Road update (May 29, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Attawapiskat First Nation to discuss the spring Groundwater Program (May 31, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person taskforce meeting between Marten Falls First Nation and Aroland First Nation (June 5, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Weenusk First Nation to provide a Community Access Road update and discuss the Indigenous Knowledge Program and community well-being (social and economic) programs (June 5, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meetings with Aroland First Nation community members to obtain feedback on the Preferred Route recommendation, existing conditions, and cumulative effects, including Project Inclusions List (June 19 and 20, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Long Lake #58 First Nation Elders and community members to present the preliminary technically preferred route (June 20, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Ginoogaming First Nation to discuss the Archaeology Assessment Report, Community Coordinator Program and upcoming engagement opportunities (July 10, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person taskforce meeting between Marten Falls First Nation and Aroland First Nation (July 11, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meetings with Aroland First Nation community members to obtain feedback on the Preferred Route recommendation including Segment 1, Dusey Lake, Segment 2, Segment 3, cumulative effects, evaluation approach and Project Inclusions List, engineering considerations, and existing conditions (valued component studies) (July 15 and 16, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meetings with Marten Falls First Nation members to confirm selection of the Preferred Route selection, cumulative effects, evaluation approach and Project Inclusions List, engineering considerations, and existing conditions (valued component studies) (July 17 and 18, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting held with Attawapiskat First Nation to discuss the Draft Aboriginal and / or Treaty Rights and Interests Existing Conditions Report (July 23, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting held with Ginoogaming First Nation to discuss the Stage 1 Archaeological Report (August 1, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person taskforce meeting between Marten Falls First Nation and Aroland First Nation (August 8, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting held with Animbiigoo Zaagi'igan Anishinaabek to discuss the Indigenous Knowledge Program (August 28, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Marten Falls First Nation to discuss Preferred Route selection, the Draft Environmental Assessment / Impact Statement, construction and design details, potential effects and mitigations, socio-economics, climate change adaptation, and offsetting (October 15, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with a professor from Laurentian University, who provided a presentation on climate change (October 24, 2024).	Not applicable	Yes	Not applicable
Individual Community Access Road Meetings	• In-person taskforce meeting between Marten Falls First Nation and Aroland First Nation (October 29, 2024).	Yes	Not applicable	Not applicable

Activity	Description	Indigenous Communities	Interested Persons	Government Agencies
Individual Community Access Road Meetings	• Virtual meeting held with Fort Albany First Nation to discuss Community Access Road updates and meaningful consultation and engagement (November 7, 2024).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtually attended the Geraldton Area Natural Resources Advisory Committee fall general meeting to deliver a presentation on the Community Access Road (November 20, 2024).	Not applicable	Yes	Not applicable
Individual Community Access Road Meetings	• Virtual meeting held with Long Lake #58 First Nation to discuss the Indigenous Knowledge Program and the community's Indigenous Knowledge collection study (February 6, 2025).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meetings with Marten Falls First Nation to present the Draft Environmental Assessment / Impact Statement and discuss the Draft Environmental Assessment / Impact Statement content (February 12 and 19, 2025).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meetings at the Three-Road Project Gathering and Expo with representatives from Animbiigoo Zaagi'igan Anishinaabek, Aroland First Nation, Attawapiskat First Nation, Constance Lake First Nation, Fort Albany First Nation, Long Lake #58 First Nation, Kashechewan First Nation, Mushkegowuk Tribal Council, Nibinamik First Nation and Red Sky Métis Independent Nation (February 19 to 25, 2025).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Constance Lake First Nation community members to provide a Community Access Road overview and present the Draft Environmental Assessment / Impact Statement (February 22, 2025).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Attended the Prospectors & Developers Association of Canada Conference in-person to deliver two presentations and host an information booth (March 2 to 3, 2025).	Not applicable	Yes	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Matawa First Nations Management to discuss the Community Well-Being Report (May 9, 2025).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Marten Falls First Nation to discuss the Draft Environmental Assessment / Impact Statement content including community well-being and cumulative effects (May 27 and 28, 2025).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• In-person meeting with Aroland First Nation community members to discuss the Draft Environmental Assessment / Impact Statement content including community well-being and cumulative effects (May 28 and 29, 2025).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• Virtual meeting with Fort Albany First Nation to discuss the community's ongoing review of the Draft Environmental Assessment / Impact Statement (June 3, 2025).	Yes	Not applicable	Not applicable
Individual Community Access Road Meetings	• The Project Team's attendance at in-person general meeting for Marten Falls First Nation in Thunder Bay (July 4, 2025).	Yes	Not applicable	Not applicable
Field Program Involvement	• Helicopter flyover to visually inspect three potential groundwater sites with Aroland First Nation (August 17 and 18, 2022).	Yes	Not applicable	Not applicable
Field Program Involvement	• Well drilling activities monitored by Aroland First Nation representatives (November 25 to December 3, 2022).	Yes	Not applicable	Not applicable
Field Program Involvement	• Helicopter flyover to inform the Geotechnical Program with Marten Falls First Nation and Aroland First Nation (July 19 and 20, 2024).	Yes	Not applicable	Not applicable
Other Notices / Newsletters	• 2021 Highlights Letter distributed to Indigenous communities via email (December 15, 2021).	Yes	Not applicable	Not applicable
Other Notices / Newsletters	• Phone calls to Indigenous communities to follow-up on the December e-blast, Winter Discussion Guide, and field notice (December 16 and 17, 2021).	Yes	Not applicable	Not applicable
Monthly E-Blasts	• Circulated Monthly Community Access Road Update E-blast: – October 2021 (November 3, 2021); – November 2021 (November 30, 2021); – December 2021 (December 15, 2021); – January 2022 (January 31, 2022); – February / March 2022 (March 15, 2022); – April 2022 (April 29, 2022); – May 2022 (May 27, 2022); – June 2022 (June 24, 2022); – July 2022 (July 26, 2022); – August 2022 (August 19, 2022); – September 2022 (September 29, 2022); – October 2022 (November 2, 2022); – November 2022 (November 25, 2022);	Yes	Yes	Yes

Archaeological Assessment Reports	• Stage 1 Archaeological Assessment Report (June 3, 2024).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Circulated an update on the Indigenous Knowledge Program which included an updated schedule and timeline for Indigenous communities to share Indigenous Knowledge (January 21 to 24, 2022).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Teleconference with Métis Nation of Ontario to discuss the Indigenous Knowledge Program (February 4, 2022).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Teleconference with Constance Lake First Nation to discuss the Indigenous Knowledge Program (and Community Coordinator Program) (April 21, 2022).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Indigenous Knowledge Program Update on the Proposed Aboriginal and / or Treaty Rights and Interests Study Areas Memo and Aboriginal and / or Treaty Rights and Interests Shapefiles were distributed via email. (August 2022).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Distributed a Save the Date for the upcoming Aboriginal and / or Treaty Rights and Interests Forum and Cultural Heritage Workshop via email (December 20, 2022).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Invitation to Aboriginal and / or Treaty Rights and Interests Forum distributed (January 13, 2023, and February 1, 2023).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Cultural Heritage Workshop in Thunder Bay at the Aboriginal and / or Treaty Rights and Interests Forum (February 8 and 9, 2023).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Indigenous Knowledge Program timeline and update letter (March 22, 2023).	Yes	Not applicable	Not applicable

Activity	Description	Indigenous Communities	Interested Persons	Government Agencies
Indigenous Knowledge Program	• Indigenous Knowledge Program timeline and update letter (June 22, 2023).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Indigenous Knowledge Program timeline and update letter (October 5, 2023).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Indigenous Knowledge Program timeline and update letter (November 10, 2023).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Draft Preliminary Aboriginal and / or Treaty Rights and Interests Existing Conditions Report distributed via email to Indigenous communities (November 28, 2023).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Distribution of community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports (June 10 to July 11, 2025).	Yes	Not applicable	Not applicable
Indigenous Knowledge Program	• Ongoing monthly outreach regarding participation in the Indigenous Knowledge Program.	Yes	Not applicable	Not applicable
Community Coordinator Program	• Distribution of letter introducing the Community Coordinator Program to 13 neighbouring Indigenous communities including job posting (March 17, 2022).	Yes	Not applicable	Not applicable
Community Coordinator Program	• Teleconference with Constance Lake First Nation to discuss the Community Coordinator Program (and the Indigenous Knowledge Program) (April 21, 2022).	Yes	Not applicable	Not applicable
Community Coordinator Program	• Ongoing monthly outreach regarding participation in the Community Coordinator Program.	Yes	Not applicable	Not applicable
Community Capacity Funding Program	• Information on the Community Capacity Funding Program sent to 15 Indigenous communities via email (October 30 to November 13, 2024).	Yes	Not applicable	Not applicable

11.7.2 Consultation and Engagement with Indigenous Communities

11.7.2.1 Marten Falls First Nation

During the preparation of the Terms of Reference and leading up to the Notice Commencement of Environmental Assessment community, meetings were designed to gather input from members and receive direction from Chief and Council.

Table 11-8 summarizes the meetings held with Marten Falls First Nation during the Assessment Process to provide updates on the Community Access Road and receive feedback. The meetings were open to all Community members and held either in Marten Falls or outside of the Community (virtual, Thunder Bay or Geraldton), up to the release of the Final Environmental Assessment / Impact Statement.

Table 11-8: Summary of Meetings with Marten Falls First Nation

Milestone	Date	Purpose	In-person / Virtual	Topics Discussed
Milestone 1	November 16 and 17, 2021	Introduction of Assessment Process and Youth Engagement Program	In-person	• This meeting provided an update on the Community Access Road and shared that the Terms of Reference for the Project had been approved. Discussions included: – Provincial environmental assessment process and schedule; – Upcoming field programs and support staff opportunities; – Indigenous Knowledge Program; and – Youth Engagement Program was delivered as part of the meeting.
Milestone 1	February 2, 2022	Community Update	Virtual	• This meeting provided an update on the Community Access Road and discussed the Assessment Process as a whole. Discussions included: – Refresher on the Community Access Road; – Update on the schedule; – Information on the environmental assessment process; – Information on the Assessment Process; – Review of questions and answers from the last community meeting; – Overview of field programs and support staff job opportunities; and – Update on the Indigenous Knowledge Program.
Milestone 2	June 28, 2022	Community Update	In-person	• This meeting featured a combination of community-specific materials and a preview of the materials to be presented at Public Information Centre #3. Discussions included: – Refresher on the Community Access Road; why it is needed and new information since the last community meeting; – Sample photographs of what the road and / or bridges could look like; – Preliminary footprint of the Community Access Road; – Guiding principles for the Assessment Process and an overview of the process; – Alternative routes, evaluation criteria, and new information on aggregate sites; – Field programs and early observations; – Considerations for land and resource use and community well-being (social, economics, and human health); – Overview of the Indigenous Knowledge Program and Indigenous land and resource use, including Marten Falls First Nation's participated to date and next steps; – Assessment of Aboriginal and / or Treaty Rights and Interests; – Advertising the Community Coordinator position and application information; – Summary of consultation, engagement, and communication efforts to date, as well as future plans; – Feedback from the last community meeting and responses provided; and – 6-month look-ahead.
Milestone 2	Marten Falls First Nation (November 2, 2022) Thunder Bay Meeting (December 6, 2022)	Community update	In-person	• This meeting featured a combination of community-specific materials and a preview of the materials to be presented at Public Information Centre #4. Discussions included: – How a route to Marten Falls will be selected; – What has been learned through field programs conducted so far; – What Marten Falls First Nation has accomplished so far through the Indigenous Knowledge Program and Indigenous Lands and Resource Use information; – Introduction to the Marten Falls First Nation Community Coordinator (living in Marten Falls); – Job opportunities; – Feedback from the last community meeting and responses provided; – Plans for the Youth Engagement Program; and – 6-month look-ahead. • The Thunder Bay meeting also included: – Introduction to a second Community Coordinator (living outside of Marten Falls); and – Feedback from the last community meeting and responses provided.

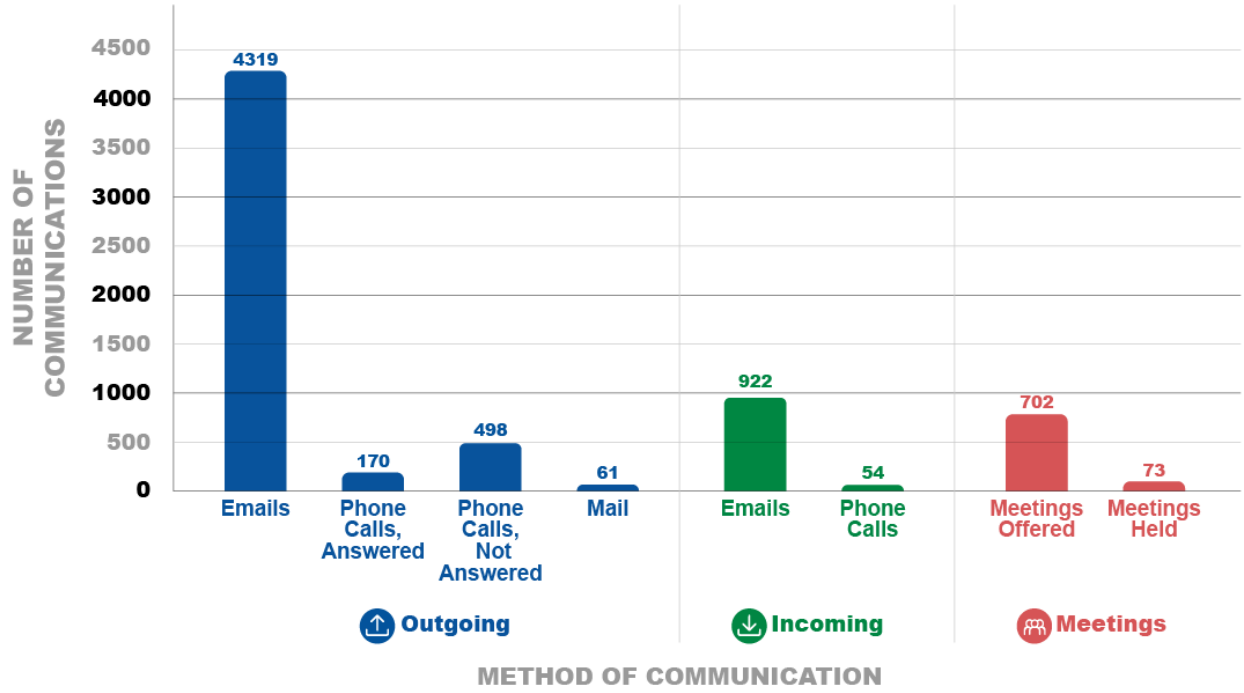
Milestone	Date	Purpose	In-person / Virtual	Topics Discussed
• **Milestone 2**	• May 15, 2023	• Engineering, Design, and Construction: Chief and Council	• Virtual	• This meeting included a presentation and discussion on the engineering, design, and construction details of the Community Access Road.
Milestone 3	Thunder Bay Meeting (October 23, 2023) In-Community Meeting (October 24, 2023)	Community Update: Marten Falls First Nation Members	In-person	• This meeting included a combination of community-specific materials and a preview of the materials to be presented at Public Information Centre #5. Discussions included: – How the Community Access Road differs from the Northern Road Link and Webequie Supply Road projects; – Information on the Assessment Process; – Steps leading to road construction; – Feedback from the last community meeting, the Aboriginal and / or Treaty Rights and Interests Forum, and the Archaeology and Cultural Heritage Workshop and responses provided; – Updates on the Indigenous Knowledge Program; – Existing conditions results for completed studies; – Route selection methods, including the pros and cons of proposed routes (alternatives), how the Preferred Route will be selected, and a preliminary technically preferred route recommendation; – Cumulative effects and the Project Inclusions List; – Overview of community well-being surveys, intended to collect social, economics, and human health information; and – 6-month look-ahead.
Milestone 3	Marten Falls First Nation (May 29, 2024)	Route Alignment	In-person	• This meeting provided a Project overview to Marten Falls First Nation Chief and Council, including an update on the changes to the technically preferred route recommendation. Discussions included: – Updated route; – Overview of existing conditions; – Details of the Assessment Process and engagement efforts; – Information on the Community Coordinator Program; and – Upcoming engagement opportunities, including the Three-Road Project Gathering and Expo.
Milestone 3	Marten Falls First Nation (July 17, 2024) Thunder Bay (July 18, 2024)	Preferred Route Recommendation	In-person	• This meeting focused on reaching a major Project milestone – approving the Preferred Route Recommendation and other Project Updates. Discussions included: – Changes to the Preferred Route recommendation based on consultation and engagement; – Updates on the Band Council Resolution (signed by Chief and Council in August 2024); – Cumulative effects assessment and the Project Inclusions List; and – Updates regarding field programs and Assessment Process.
Milestone 4	Thunder Bay Meeting (October 15, 2024) Marten Falls First Nation (October 17, 2024)	Preferred Route Selection	In-person	• This meeting offered a chance for community members to learn about the Assessment Process and review new information related to various study areas. Discussions included: – Preferred Route including how community feedback played a role in its refinement; and – New information on the Draft Environmental Assessment / Impact Statement review process, construction, socio-community studies, potential effects and mitigation measures, offsetting activities, cumulative effects, and climate change challenges. • The Marten Falls First Nation in-community meeting scheduled for October 17, 2024, was cancelled due to unforeseen circumstances in the Community.
Milestone 4	Marten Falls First Nation (February 12, 2025) Thunder Bay (February 19, 2025)	Draft Environmental Assessment / Impact Statement Release	In-person	• The Draft Environmental Assessment / Impact Statement was delivered for Community members' early viewing (hard copy and digital files). This provided an opportunity to discuss and ask questions about the draft documents and next steps. The in-community session held was structured as an open house / drop-in and the Thunder Bay session provided a presentation and open discussion period. Discussions included: – Preferred Route and questions around construction and designs; Assessment Process schedule and when construction is expected to begin; – How feedback from other Indigenous Communities had on the Community Access Roa; and – In addition to the full Draft Environmental Assessment / Impact Statement, Assessment Summary Packages were shared with Community members, which included plain language summaries to support their review.

Milestone	Date	Purpose	In-person / Virtual	Topics Discussed
Milestone 4	Marten Falls First Nation (May 27, 2025) Thunder Bay (May 28, 2025)	Draft Environmental Assessment / Impact Statement Review	In-person	• This meeting included a combination of community-specific materials and materials to be presented at Public Information Centre #6. Discussions included: – Purpose of the Draft Environmental Assessment / Impact Statement; – What was heard on the Draft Environmental Assessment / Impact Statement; – How the Community Access Road will affect community well-being for Marten Falls and nearby communities and the opportunity to participate in a Story Beads exercise, and Country Foods Program; – Cumulative Effects Assessment process and updated Project Inclusions List; – Land and Resource Use; – Opportunity to participate in a bridge / culverts navigability exercise; and – How to provide feedback on the Draft Environmental Assessment / Impact Statement and upcoming activities.
Milestone 4	Thunder Bay (July 4, 2025)	Marten Falls First Nation General Meeting	In-person	• Marten Falls First Nation invited a member of the Project Team to present on the Community Access Road. Discussions included: – Assessment Process and Environmental Assessment / Impact Statement schedule; – Feedback received during the Draft Environmental Assessment / Impact Statement; – Consultation and engagement activities that occurred during the Draft Environmental Assessment / Impact Statement review period; and – Update on the Country Foods Program.

Marten Falls First Nation, as the Proponent and the community most directly affected, played a defining role in shaping the Final Environmental Assessment / Impact Statement. Their direction, feedback, and knowledge influenced both the process and outcomes in many ways:

- **Early review and direction on engagement materials** - as Proponent and a potentially affected community, Marten Falls First Nation reviewed and shaped presentations, discussion guides, webinars, and video content before these materials were shared with other communities, interested persons or government agencies, helping to ensure alignment with Community expectations and knowledge.
- **Influence on technical work** - feedback helped refine route alignment, assessment focus, and study parameters (for example, areas of concern, valued components), supporting adjustments reflected in the Final Environmental Assessment / Impact Statement.
- **Refinement of the Preferred Route** - input (through community meetings, technical discussions, and leadership reviews) directly contributed to refining the preliminary technically preferred route and confirming the Preferred Route. This culminated in a Band Council Resolution in August 2024, endorsing the Preferred Route.
- **Consent for the Final Environmental Assessment / Impact Statement Submission** - formal support was provided through a second Band Council Resolution, helping to ensure the submission reflects Community priorities and values.

11.7.2.2 Neighbouring Indigenous Communities



In addition to the broader consultation and engagement activities described in **Section 11.5**, the Project Team, throughout Milestones 1 to 4, carried out focused outreach and engagement efforts specifically with neighbouring Indigenous communities. This consultation and engagement provided essential insights into community priorities, land use, cultural values, and technical considerations, including potential sources of aggregate material. Through a combination of broad communications, meetings, field study discussions, Indigenous Knowledge sharing, funding-program engagement, community-specific conversations, and participation in provincially-supported forums, communities offered detailed feedback on environmental, cultural, socio-economic, and rights-related topics. This input helped shape a clear understanding of community interests and concerns throughout the Assessment Process.

Results of consultation and engagement with neighbouring Indigenous communities is summarized in **Section 11.7.2.2.11** and described in more detail in the Record of Consultation and Engagement for Indigenous Communities in **Appendix X**.

11.7.2.2.1 Email and Phone Outreach

The Project Team maintained consistent communication with neighbouring Indigenous communities through email and telephone outreach. Between 2021 and 2025, over 4,300 emails were issued, supported by extensive phone outreach, as part of nearly 4,500 total contact attempts (**Figure 11-3**). These communications provided monthly updates, milestone notifications, and circulation of key documents, including the Milestone Progress Reports, the Existing Conditions Report, the Community Well-Being Technical Support Document (**Appendix T**), Stage 1 and 2 Archaeological Assessment Reports, the community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports and the Draft Environmental Assessment / Impact Statement, released in early 2025.

Figure 11-3: Summary of Communication with Indigenous Communities throughout the Assessment Process

Emails and calls also shared: updates on the Indigenous Knowledge Program; information about the transition from the Community Coordinator Program to the Community Capacity Funding Program in late 2024 (including continuous follow-up to

encourage participation); and seasonal notices about ongoing field studies. Invitations were also issued for Public Information Centres, Aboriginal and / or Treaty Rights and Interests Forums (two), Three Roads Gathering and Expo events (two), webinars, and community meetings. Additional community-specific outreach responded to questions, clarified funding details, requested interest in scheduling meetings with the Project Team, addressed feedback on technical documentation, and supported the submission of Indigenous Knowledge.

11.7.2.2.2 Meeting and Discussions

Meetings with neighbouring Indigenous communities occurred throughout all milestones and were held in the Marten Falls First Nation community, Thunder Bay, Geraldton, or virtually. Across all four milestones, the Project Team offered approximately 700 meetings and held 73 with neighbouring communities.

- **Milestone 1 (2022): 9 meetings with 4 communities** - Early discussions centred around: building Community Access Road awareness; funding questions related to the Indigenous Knowledge Program and Community Coordinator Program; opportunities to participate in field programs; Aboriginal and / or Treaty Rights and Interests; alternative routes; environmental concerns and climate change; COVID-19 effects on consultation and engagement; cumulative effects; community well-being (including access and safety concerns); and Public Information Centre #3.
- **Milestone 2 (2022–2023): 12 meetings with 7 communities** - Building on Milestone 1 topics, discussions expanded as communities reviewed early technical materials and provided more detailed feedback. New and / or deepened topics included: review of Progress Report 1 and the Draft Interim Record of Consultation and Engagement; Public Information Centre #4; feedback on field studies and continued interest in participation; comments related to Aboriginal and / or Treaty Rights and Interests; areas of interest and cultural heritage; environmental impacts to wildlife, vegetation, and water; more specific views on route alignments; consultation and engagement methods; socio-economic impacts; and concerns and comments related to Stage 1 and Stage 2 Archaeology Assessment Reports.
- **Milestone 3 (2023–2024): 25 meetings with 8 communities** - New or Milestone-specific topics discussed included engagement related to: Public Information Centre #5; the second Aboriginal and / or Treaty Rights and Interests Forum; Progress Reports 2 and 3; land use (hunting and fishing); areas of interest and cultural heritage; engineering considerations (bridges, crossings,

and routes); construction and operational topics (ownership, traffic, and maintenance); and community excitement about the Community Access Road, including interest related to job opportunities and improved access.

- **Milestone 4 (2025): 27 meetings with 13 communities** - New or Milestone-specific topics discussed included engagement related to: Public Information Centre #6; transition from the Community Coordinator Program to the Community Capacity Funding Program; more detailed feedback on engineering and construction (timelines, processes, and camps); expanded discussions on socio-economic conditions and human health; the Country Foods Program; and continued expressions of interest in job opportunities and improved access. Meetings also addressed community-specific Aboriginal and / or Treaty Rights and Interests in relation to the Draft Impact Assessment Reports and the Stage 1 Archaeological Assessment Report.

11.7.2.2.3 Milestone Progress Reports

Four additional consultation and engagement reports (Milestone Progress Reports) were provided to Indigenous communities for review and comment at the environmental assessment milestones described below. For more information about the Ministry of the Environment, Conservation and Parks requirements for Milestone Progress Reports, refer to **Section 11.2.2**.

- **Milestone 1: Notice of Commencement of Provincial Environmental Assessment** - sent to Indigenous communities on December 6, 2022. The reporting period covered October 29, 2021, to June 30, 2022, and focused on the introduction of the Community Access Road;
- **Milestone 2: Effects Assessment Methods** - sent to Indigenous communities on November 27 and 29, 2023. The reporting period covered July 1, 2022, to May 31, 2023, and focused on the development of the Effects Assessment methodology, including review by regulators and presentation of the Effects Assessment methodology at Public Information Centres. Indigenous communities were invited to share community values and topics of interest (including cumulative effects), and proposed impact management measures to avoid, mitigate, or offset effects;
- **Milestone 3: Identification of Preferred Alternatives** - sent to Indigenous communities on November 28 and 29, 2024. The reporting period covered June 1, 2023, to July 31, 2024, and supported engagement activities related to the identification of preferred alternatives. Input was obtained on alternative route options, proposed mitigation measures, and the environmental, socio-economic,

cultural, technical, and cost considerations used in route selection. Consultation during this milestone included a strong focus on the cumulative effects assessment methodology, including identification of projects and activities that could act cumulatively with the Community Access Road. The milestone concluded with the identification of a preliminary preferred alternative that involved validation of information from Marten Falls First Nation and other Indigenous communities. Confirmation of the Preferred Route was achieved through submission of the Final Route Recommendation Memo to Marten Falls First Nation Chief and Council, resulting in a Band Council Resolution for the Preferred Route; and

- **Milestone 4: Draft Environmental Assessment / Impact Statement** - sent to Indigenous communities on January 16, 2026. The reporting period covered August 1, 2024, to September 5, 2025, and focused on efforts related to the preparation and release of the Draft Environmental Assessment / Impact Statement in support of the Final Environmental Assessment / Impact Statement submission. Feedback was sought on the Draft document, proposed impact management, monitoring and adaptive management plans, cumulative effects assessment results, and draft conclusions. This milestone focused on consultation and engagement with Indigenous communities through the Indigenous Knowledge Program, Community Capacity Funding Program, community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports, meetings, webinars, and Public Information Centre #6 to support understanding and encourage feedback during the Indigenous review period of the Draft Environmental Assessment / Impact Statement.

11.7.2.2.4 Field Studies Engagement

Field studies engagement was carried out throughout Milestones 1 to 4, providing early notice and opportunities for neighbouring Indigenous communities to participate in or provide input into the design and implementation of field programs. Seasonal field notices were issued during winter, spring, summer, and fall from 2022 to 2025, describing:

- Study purpose, timing, and locations;
- Disciplines such as wildlife, birds, fish and fish habitat, groundwater and geochemistry, vegetation, wetlands, peatlands, terrain, and archaeology;
- Field crews and equipment; and
- Opportunities for Indigenous communities to ask questions or identify sensitive areas.

Indigenous communities were regularly contacted regarding existing conditions studies and ongoing fieldwork, and many expressed interest in specific programs, particularly wildlife and archaeology. Input included observations of wildlife presence, habitat conditions, trapline areas, archaeological locations, and culturally sensitive use areas. Field monitors from Marten Falls First Nation and Aroland First Nation also participated in field programs.

During Milestone 3, Indigenous community input informed updates to study plans. For example, several communities provided comments about water crossings, caribou movement areas, or sensitive cultural landscapes that required additional attention.

In Milestone 4, supplementary fieldwork continued to support the Draft Environmental Assessment / Impact Statement, with ongoing communication to communities through emails, phone calls, and opportunities to ask questions about the purpose or timing of studies.

11.7.2.2.5 Community-Specific Engagement Activities

While all Indigenous communities received the same core opportunities, several neighbouring Indigenous communities engaged more deeply on specific topics. For example,

- Attawapiskat First Nation provided detailed input on Aboriginal and / or Treaty Rights and Interests materials that resulted in the expansion of the Regional Study Area for Attawapiskat First Nation's Aboriginal and / or Treaty Rights and Interests assessment;
- Animbiigoo Zaagi'igan Anishinaabek, Attawapiskat First Nation, Fort Albany First Nation, Long Lake #58 First Nation, and Red Sky Métis Independent Nation participated in meetings to discuss the Aboriginal and / or Treaty Rights and Interests Existing Conditions Report;
- Long Lake #58 First Nation, Constance Lake First Nation, Ginoogaming First Nation, and the Métis Nation of Ontario offered culturally relevant information regarding areas of archaeological importance through their review of the Stage 1 and Stage 2 Archaeological Assessment Reports; and
- Aroland First Nation participated in field monitoring programs and community-specific meetings in Milestones 3 and 4 and discussions through the Marten Falls First Nation and Aroland First Nation taskforce.

At the May 2025 community member meetings, Marten Falls First Nation and Aroland First Nation members participated in a Story Beads exercise to create a space for

intergenerational dialogue and shared storytelling, using beadwork as a metaphor. Participants were offered a variety of coloured beads, each representing a theme. Green represented land, blue water, yellow food, purple youth, red healing, black challenges, and white hope. Participants were asked to select three to five beads, string them onto a cord or safety pin, and share the story or memory behind their choices. Participants could share their story or memory through writing, drawing, or sharing verbally with a facilitator. Community members shared their hopes and concerns around the Community Access Road including increased access to food and reduced costs of living, along with concerns about outsider access, and substance abuse.

Some communities participated selectively based on internal capacity and priorities. Neskantaga First Nation ceased engagement in March 2023 following correspondence related to litigation with the Province of Ontario about environmental assessment consultation processes. While the Project Team continued to outreach and provide information, no further engagement occurred after March 29, 2023.

11.7.2.2.6 Indigenous Knowledge Program Engagement

Communications with Indigenous communities on the Indigenous Knowledge Program began in December 2019. Funding was offered to communities who expressed interest in the program starting in the summer of 2021 and continued beyond Milestone 4. Neighbouring Indigenous communities received regular communication about:

- How Indigenous Knowledge would be gathered, handled, and incorporated;
- Expectations for participation and confidentiality;
- Available tools and supports for sharing knowledge; and
- Coordination with field studies and valued component assessments.

The intent of the Indigenous Knowledge Program was to collaborate with interested Indigenous communities to explore how relevant knowledge could meaningfully inform the Assessment Processes as well as Project planning and design. Outreach efforts intensified during Milestone 3, a period in which Indigenous Knowledge was particularly important for identifying and assessing route alternatives. During this phase, Indigenous Knowledge could be considered alongside scientific and technical information to enhance understanding of existing conditions, inform the prediction of potential effects, and support the development of appropriate mitigation and monitoring measures. Indigenous Knowledge Program outreach continued during the Draft Environmental Assessment / Impact Statement review period, particularly as community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports were circulated in June and July 2025.

At the time of the submission of the Final Environmental Assessment / Impact Statement, seven Indigenous communities had participated in the Indigenous Knowledge Program. Feedback provided on the Draft Environmental Assessment / Impact Statement indicated strong interest from several communities in sharing their Indigenous Knowledge, cultural perspectives, and traditions. Efforts to receive, understand, and integrate Indigenous Knowledge from interested communities will continue in detail design.

11.7.2.2.7 Community Coordinator / Community Capacity Funding Program

Funding-related engagement supported neighbouring Indigenous communities' participation across all milestones. The Community Coordinator Program was introduced in 2022 through email, phone outreach, and meetings. Communities received program information packages, job postings, and guidance on funding eligibility and reporting.

Throughout Milestones 1 to 3, the Project Team followed up with communities to confirm interest, support onboarding, and clarify how the program could be used for document review, meeting attendance, and internal coordination. Some Indigenous communities expressed interest in the program, however only Marten Falls First Nation took part in it.

In November 2024, the program evolved into the Community Capacity Funding Program. Communities were contacted to explain the new funding parameters, including how it will support review of the Draft Environmental Assessment / Impact Statement, and provide flexibility for internal review processes and engagement in meetings and webinars. This outreach continued beyond Milestone 4 as communities worked through the Draft Environmental Assessment / Impact Statement and community-specific Aboriginal and / or Treaty Rights and Interests reports. A total of nine Indigenous communities participated in the program and of those nine, eight provided feedback on the Draft Environmental Assessment / Impact Statement.

11.7.2.2.8 Provincially-Supported Forums

Forums have been a successful approach to consultation and engagement. These provincially-supported events offer a space for Indigenous communities to gather over several days to collect information and discuss the three road projects independently undergoing environmental assessments in the area: the Community Access Road, Webequie Supply Road, and Northern Road Link. Although the three road projects are distinct and in different phases of the environmental assessment, they are similarly regarded by neighbouring communities. Hosting an event forum on all three road

projects was an efficient way to engage Indigenous communities without the associated consultation fatigue.

- Two Aboriginal and / or Treaty Rights and Interests Forums were held in Thunder Bay on February 8 and 9, 2023, and November 21 to 23, 2023, respectively. The Province provided funding for 2 to 3 participants from each Indigenous community to attend the event in person. The two forums provided a private and inclusive space for representatives of Indigenous communities to meet with representatives from the Province and the Project Teams for the Community Access Road, Northern Road Link, and Webequie Supply Road;
- Two Three Roads Gathering and Expos were also held. One occurred in Thunder Bay from June 11 to 13, 2024, and a second occurred in Thunder Bay on February 19 and 20, 2025, and in Timmins on February 25 and 26, 2025. The Province funded up to three participants from each Indigenous community to attend the event in person. The forums were hosted by the company Indigenous Community and Engagement, with support from the Project Teams for the Community Access Road, Northern Road Link, and Webequie Supply Road. The expos provided a space where participants could learn more about the three unique road projects, ask questions, and share feedback;
- On the first day of the June 2024 Three-Road Gathering and Expo, Elders were invited to gather and engage with Project Teams for all three road projects to share their perspectives. The second and third days of the forum included: technical presentations on water, peatlands, and building roads on peatlands; an expo-style forum; and a half-day workshop to review the anticipated schedules for circulating the Draft Environmental Assessment / Impact Statement for the Community Access Road and the Webequie Supply Road. The goal was to inform participants about the proposed review process and seek clarifying questions in advance of the release of the Draft Environmental Assessment / Impact Statement; and
- The February 2025 Three-Road Gathering and Expo included presentations on the Community Access Road, Northern Road Link, and Webequie Supply Road. The 2 days included: an expo-style forum; and private breakout rooms for individual Indigenous communities to review the Community Access Road's Draft Environmental Assessment / Impact Statement, ask questions on the review process, and provide feedback. The Assessment Summary: Draft Environmental Assessment / Impact Statement was distributed to attendees and included a USB that contained the Draft Environmental Assessment / Impact Statement, technical supporting documents and plain language summaries.

11.7.2.2.9 Review Period of the Draft Environmental Assessment / Impact Statement

Preparation for the release began between September 24 and 26, 2024, when letters were issued to all 31 Indigenous communities, Tribal Councils, and Political Treaty Organizations / Provincial Territorial Organizations engaged on the Community Access Road. These letters advised recipients of the upcoming release, included a frequently asked questions document, and requested confirmation of key contacts and preferred formats for receiving the Draft Environmental Assessment / Impact Statement. In the months leading up to release, monthly E-blasts, videos, and social media posts shared information about the upcoming Draft Environmental Assessment / Impact Statement.

On February 12 and 19, 2025, printed copies of the Draft Environmental Assessment / Impact Statement and supporting documents were delivered to Marten Falls First Nation members in-community and in Thunder Bay. On February 19, 2025, Indigenous community key contacts received the Draft Environmental Assessment / Impact Statement link by email, along with links to supporting documents, including the Assessment Summary Package. Hard copies were sent to communities that requested them, and copies were also made available for viewing at multiple public locations and events.

Following the early release of the Draft Environmental Assessment / Impact Statement, the Project Team provided continued support through email, telephone outreach, and distribution of hard copies upon request. Additional communication occurred through monthly E-blasts, videos, website updates, and other information channels.

Throughout the review period, the Project Team offered meetings to assist communities in navigating the Draft Environmental Assessment / Impact Statement. Topic-specific webinars were delivered between April and June 2025, and community-specific meetings tied to Public Information Centre #6 were also offered. Indigenous communities could submit comments by email, phone, or mail until the extended deadline of September 5, 2025. More than 1,900 comments were received on the Draft Environmental Assessment / Impact Statement. Of these, over 1,000 comments were submitted by 9 Indigenous communities: Aroland First Nation, Animbiigoo Zaagi'igan Anishinaabek, Constance Lake First Nation, Fort Albany First Nation, Ginoogaming First Nation, Kashechewan First Nation, Mushkegowuk Council, Nibinamik First Nation, and Weenusk First Nation.

All comments and responses are included in the Feedback and Response Log (**Appendix C**), which documents each submission, the Project Team's response, and

whether changes were made to the Final Environmental Assessment / Impact Statement.

11.7.2.2.10 Community-Specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports

Community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports were prepared and issued to each community in June and July 2025, with a 90-day review period.

These community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports included Indigenous Knowledge information received from the community prior to January 2025, along with information obtained from publicly available sources. These community-specific reports outlined the assessment process for Aboriginal and / or Treaty Rights and Interests related to the Community Access Road. Communities were given 90 days to provide feedback before their Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Report would be finalized in October 2025. The Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports are confidential, therefore feedback provided is not available publicly. An Aboriginal and / or Treaty Rights and Interests Summary Report is, however, provided in **Appendix O** of the Final Environmental Assessment / Impact Statement.

11.7.2.2.11 Summary of Issues and Feedback from Indigenous Communities

Throughout Milestones 1 through 4, Indigenous communities shared input on a wide range of topics. Feedback included observations from field programs, information about wildlife and culturally significant areas, comments on Aboriginal and / or Treaty Rights and Interests, concerns regarding environmental conditions and cumulative effects, route alignment feedback, input on archaeology, requests for funding support, recommendations about study areas, and comments on consultation methods, timelines, and Indigenous Knowledge and Community Capacity Funding program participation. Some feedback was detailed or specific, while other input reflected general interests, concerns, or requests for more information.

Indigenous community input contributed to the Assessment Process in multiple ways. Feedback influenced field program design, helping to ensure that appropriate measures were in place to limit disruption to people and wildlife, as well as timing field work to accommodate key events such as seasonal hunting periods. Field Monitors from Aroland First Nation and Marten Falls First Nation also participated in a number of

programs offering insights, expertise and advice. Feedback also supported route refinements and selection of the Preferred Route, informed revisions to Aboriginal and / or Treaty Rights and Interests study areas, and shaped the development of community-specific Aboriginal and / or Treaty Rights and Interests Draft Impact Assessment Reports. Community-identified archaeological areas were incorporated into fieldwork and updated archaeology reporting. Cumulative effects assessment methods and the Project Inclusions List were shared and updated in response to engagement. Requests for timeline extensions resulted in extensions to both the Impact Statement schedule and Draft Environmental Assessment / Impact Statement review period. Feedback also informed updates to materials, including maps, language supports, and consultation approaches.

Table 11-9 provides a high-level summary of input and information received from Indigenous communities from October 29, 2021, to September 5, 2025, from the start of the Environmental Assessment for the Community Access Road to the end of the review period for the Draft Environmental Assessment / Impact Statement. The table indicates whether the feedback received informed the Assessment Process. While some feedback directly informed the progression of each milestone or the overall Assessment Process, some input was broad, with limited details (which required ongoing follow-up for additional information from the commenters), or consisted of expressions of general interests or concerns.

Table 11-9: Summary of Input and Information Received from Indigenous Communities and Influence on Milestones 1, 2, 3, and 4

Indigenous Communities Input and Information	How the Development of Milestones 1, 2, 3, and 4 Has Been Informed
• Specific feedback provided on environmental existing conditions: – Specific feedback was provided on the bird field program, including birds observed and comments on their habitats; – Specific feedback was provided on the wolverine field program; – Confidential information regarding the Albany River was provided and is considered as Indigenous Knowledge; – Caribou were identified in the District of Kenora; – Requests to participate in field programs were made; and – Feedback on the Community Access Road footprint was provided, specifically on aggregates.	• Bird observations and comments on their habitats were included in the bird field program to collect bird and Species at Risk data, including habitat features (**Section 8.2.68.2.6.6** and **8.2.6.6**); • 1 site of the wolverine hair snag was changed based on feedback provided from Marten Falls First Nation; • The Assessment Process has been informed by confidential information shared about the Albany River; • General identification of caribou location(s) has been used to aid the field investigations in the Ungulates Technical Support Document (**Appendix M**) and is considered in **Section 8.2.7**; • Members of Marten Falls First Nation and Aroland First Nation were invited to participate in field programs. For the Groundwater and Geochemistry field program, including a flyover and planning for the subsequent drilling program, Aroland First Nation joined the flyovers on July 19 and 20, 2024. Marten Falls First Nation members were able to participate in the summer groundwater monitoring in August 2024, the fall groundwater monitoring in September and October 2024, and the Stage 2 Archaeological Assessment in August 2025; and • Feedback on aggregate sites to support the construction on Segment 2 resulted in changes to the Preferred Route (**Section 4.4.2**). Specifically, feedback from Marten Falls First Nation members resulted in aggregate sites near the Albany River being removed from the Preferred Route.
• Concerns related to environmental existing conditions; additional details requested: – It was noted that a spawning area could be relocated if it would be disrupted by the Community Access Road; – Concern was expressed regarding watersheds; – Concern was expressed regarding caribou migration and impacts to gathering rights; – Concern was expressed related to salting on the road and impacts to nearby rivers; – Alternative 1 of Segment 2 was identified as a sensitive and very precious area; and – It was noted that the Community Access Road should not impede fish passage.	• Specific information was not provided, which made it challenging to address the concerns. Below is information on how Marten Falls First Nation attempted to address these with the limited information in the Environmental Assessment / Impact Statement: – Information on specific spawning areas near the Preferred Route was not provided. It should be noted that the selection of the Preferred Route was informed and chosen based on Indigenous Knowledge received, as well as fish and fish habitat information (**Section 4**). Specific mitigation measures are listed in **Table 10-1** of the Fish and Fish Habitat Technical Support Document (**Appendix G**); – An assessment of the existing watershed has been included in **Section 8.1.4.1**. It includes information on the main characteristics of the tertiary watersheds within the Regional Study Area and how the Regional Study Area was selected; – General identification of caribou location(s) has been used to aid the field investigations in the Ungulates Technical Support Document (**Appendix M**) and is considered in **Section 8.2.7.1**; – Information received to date on caribou migration and impacts to gathering rights has been considered in **Section 9.4.5**. Furthermore, confidential individual Aboriginal and / or Treaty Rights and Interest reports will be prepared for each Indigenous community. These consider caribou and impacts to gathering rights for those communities which identified caribou as part of their Aboriginal and / or Treaty Rights and Interests; – Materials used for winter maintenance, like salt or sand, depend on the type of road. The future owner / operator of the road will have specific approved products, as is the case with the Ministry of Transportation. It is unknown at this time who will own the Community Access Road. Generally, unpaved roads like the Community Access Road do not use salt for de-icing; – Comment on Alternative 1 of Segment 2 was noted and has been considered in the route selection. Alternative 1 is not part of the Preferred Route; and – Comments on fish passage have been considered when developing mitigation measures, such as constructing crossings in a manner that maintains downstream flows and fish passage. All potential effects and recommended mitigation measures and monitoring are included in **Section 9.3.3.5**.

Indigenous Communities Input and Information	How the Development of Milestones 1, 2, 3, and 4 Has Been Informed
• Interests related to environmental existing conditions; additional details requested: – Several communities indicated interest in different topics related to existing conditions without providing specific feedback or comments. One example includes the request to receive field program results for caribou when they become available; – Some communities and community members shared information on traplines within the Study Area and trapline locations; – Several communities provided comments on the Aboriginal and / or Treaty Rights and Interests Existing Conditions Report and the overall assessment of their Aboriginal and / or Treaty Rights; – Several communities provided feedback on their community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Report, after September 5, 2025; and – Some communities provided comments on the Stage 1 and 2 Archaeological Assessment Reports and identified areas of archaeological importance.	• Interest in topics has been noted for each community. Marten Falls First Nation distributed discussion guides related to field programs, educational videos, and webinars on valued components. Information on field programs were shared in the monthly Community Access Road updates and in seasonal Field Notices (sent via email and posted on the Community Access Road website). Early observations and methods for field programs completed to date have been provided at Public Information Centre #3, Public Information Centre #4, and Public Information Centre #5 as information has become available. Meetings were offered based on specific topics of interest to solicit additional feedback and issues. Field program results for individual disciplines are available in **Section 8**; • Any information received on traplines in the Study Area was mapped and considered in the Assessment Process. Additional information on Trapping and Traplines in the Project Study Area can be found in the Final Environmental Assessment / Impact Statement in **Section 8.3.6**, **Section 8.3.9**, and **Figure 8.3-17**. Additionally, **Appendix U** includes information on trapping in Section 5.1.6 and Figure 5-2; • Meetings occurred with five communities (Animbiigoo Zaagi-igan Anishinaabek, Attawapiskat First Nation, Fort Albany First Nation, Long Lake #58 First Nation and Red Sky Métis Independent Nation) to discuss the Aboriginal and / or Treaty Rights and Interests Existing Conditions Report. Comments received during meetings and via email from all communities were considered in the development of the community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Report. Community-specific Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports were distributed in June and July 2025. Final community-specific Aboriginal and / or Treaty Rights and Interests Reports will be available to each Indigenous community in Spring 2026; and • Any areas of archaeological importance noted in feedback for the Stage 1 and 2 Archaeological Assessment Reports were assessed in fieldwork and considered in updated versions of the reports. All areas retaining archaeological potential will require further assessment, including physical inspection, even if the area is only accessible by helicopter. More information on Archaeology and Cultural Heritage are included in **Section 8.3.6**, **Section 9.5.5**, **Section 10.4.4**, and **Section 10.4.5**.
• Route alignment: – A variety of comments were provided on the route alignment near Marten Falls, including: river and ice levels can be high near Marten Falls and there are locations where the bank is eroding and could affect the road; intense rain could damage the road and impact streams due to erosion; safety concerns were raised regarding truck activities (including dust, noise, low visibility, and speeding) north of the airport and children who play in the same area; and concerns regarding how the Community Access Road may interfere with Marten Falls First Nation activities (for example, gathering firewood, social events); – Feedback was obtained through Marten Falls First Nation community meetings and Public Information Centre #5 contributing to the Preferred Route selection. During October 2023, 2 in-community meetings and Public Information Centre #5 were held to receive feedback on the preliminary technically preferred route recommendation. Many comments were received regarding the proposed route for Segment 2 (Alternative 1: Albany Crossing). Community input did not align with the technically preferred segment proposed by the Project Team. Community members indicated that they did not want the route running along the Albany River and cited a range of concerns including short and longer-term impacts on the river, wildlife, and vegetation, as well as the enjoyment of the river; and – General comments received by communities on the Community Access Road potentially impacting and disturbing key traditional and cultural areas that intersect with the proposed route for the Community Access Road.	• Concerns related to the route alignment closer to Marten Falls were noted and were considered as part of the Route Selection Process. The evaluation has identified the Preferred Route for the Community Access Road, temporary infrastructure and aggregate sources with the least potential for negative effects, greatest opportunity for mitigating negative effects and greatest benefits to the community. **Appendix A** includes the metrics tables with the information used to select the Preferred Route, which considered safety and erosion; and • Based on community members' feedback, the preliminary technically preferred route recommendation was refined to reflect the feedback heard during the October 2023 meetings. The Preferred Route recommendation was altered to reflect the community's preference to have Alternative 4 be the preferred alternative for Segment 2 (Albany Crossing) (**Section 4.4.2**). Receiving Indigenous Knowledge for the area between late 2023 and mid-2024 further confirmed that Alternative 4 for Segment 2 was the decision supported by Marten Falls First Nation Chief and Council and community members. A Band Council Resolution from Marten Falls First Nation Chief and Council confirming the Preferred Route, which considered Alternative 4 was signed by Chief and Council on August 26, 2024.

Indigenous Communities Input and Information	How the Development of Milestones 1, 2, 3, and 4 Has Been Informed
• Cumulative effects, road projects and regional assessment: – Some communities expressed concerns regarding cumulative effects / impacts in the Community Access Road area, including the scope of the Environmental Assessment, impacts from all three road projects (for example, Community Access Road, Webequie Supply Road, and Northern Road Link), the Regional Assessment, and a moratorium on the Ring of Fire activities; – Some communities expressed ongoing concerns with cumulative effects impacts in relation to other road projects and caribou; and – A community provided feedback on Indigenous Knowledge and land and resource use by providing a community-specific Indigenous Knowledge and Land Use Study Report. The report asked the Project Team to consider of cumulative impacts of past and current resource development projects and noted specific concerns including ability to use the lands, water and environment, ease of access to areas, and upcoming development pressures in the region.	• Some of the comments received were directed to the government agencies (for example, Ministry of Energy and Mines; Ministry of Natural Resources and Forestry; Ministry of the Environment, Conservation and Parks; and the Agency) to respond to as they were outside of the scope of the Community Access Road; • In terms of cumulative effects, if specific details are provided, they are considered as part of **Section 10**. This section includes predicted cumulative effects of the Preferred Route with the effects of past, present and reasonably foreseeable projects. Cumulative effects assessment methods and the Project Inclusions List were shared during the Identification of Preferred Alternatives milestone at Public Information Centre #4, at the second Aboriginal and / or Treaty Rights and Interests Forum, and during community meetings in July 2024. An updated Project Inclusions List was shared during the Review of the Draft Environmental Assessment / Impact Statement milestone at Public Information Centre #6 and during community meetings in May 2025; and • The Project Team considered the feedback received through the Indigenous Knowledge and Land Use Study Report and incorporated it into the community-specific Aboriginal and / or Treaty Rights Impact Assessment Report.
• Impacts from COVID-19: – Some communities expressed inability to effectively engage with their community members due to the COVID-19 pandemic.	• Marten Falls First Nation worked with each Indigenous community's preference for how they would like to be consulted and engaged, whether virtually or in person, in light of the COVID-19 pandemic or other crises. Custom consultation plans and protocols were also offered.
• Timeline extensions: – Some communities requested extended Project timelines for both the federal and provincial processes; and – Some communities requested extended Project timelines for providing feedback on the Draft Environmental Assessment / Impact Statement.	• Questions regarding timeline extensions will continue to be addressed, with an effort to understand the needs of each community; • On November 4, 2022, a request for an Impact Statement extension was submitted to the Agency; the extension was granted on January 13, 2023. On November 25, 2022, Marten Falls First Nation advised communities of the Impact Statement Extension Request. Communities were also advised of the Impact Statement timeline extension approval on January 13, 2023, by the Agency; and • Multiple requests were received from Indigenous communities to extend the review period for the Draft Environmental Assessment / Impact Statement after June 23, 2025. Requests were granted, and the comment capture period was extended until September 5, 2025.
• Request for funding: – Some communities expressed need for provincial funding to participate in consultation and engagement activities. There has also been ongoing coordination to onboard communities to the Indigenous Knowledge Program, Community Coordinator Program, and Community Capacity Funding Program, with funding provided by the Project Team.	• While participant funding is issued by the Province and not the Project Team, requests have been shared with the Province for a response; and • Additional funding for Indigenous communities includes participation in the Indigenous Knowledge Program, Community Coordinator Program, Community Capacity Funding Program, and participation in field monitoring program(s) for Marten Falls First Nation and Aroland First Nation. Marten Falls First Nation has followed up with Indigenous communities through phone and email throughout Milestones 1, 2, 3, and 4 regarding funding opportunities (as part of **Section11**'s reporting time period and will continue to do so).
• Revision to Aboriginal and / or Treaty Rights and Interests Study Areas for the Environmental Assessment / Impact Statement: – Feedback from Indigenous communities and the collected information was used to select the Preferred Route. This included concerns regarding revising the Aboriginal and / or Treaty Rights and Interests study areas to focus on the technically Preferred Route.	• Changes were made to the Aboriginal and / or Treaty Rights and Interests for the Environmental Assessment / Impact Statement, which included an increase to the size of the Local Study Area from a 5 kilometre to a 10 kilometre buffer. Changes were also made to the Regional Study Area, increasing its size to more than double the original area; and • In addition, based on inputs from Indigenous communities and groups to date about the potential for the Community Access Road to influence Aboriginal and / or Treaty Rights and Interests outside of the Regional Study Area, given the ranges and movements of caribou, a Caribou Regional Study Area has also been identified.
• Indigenous Knowledge Program participation: – Several Indigenous communities initially expressed concerns related to the Indigenous Knowledge Program, namely timing, issues with gathering to collect Indigenous Knowledge, limited capacity and funding, as well as how the sensitive information would be used; and – Several communities provided Indigenous Knowledge through the Indigenous Knowledge Program.	• Offers to meet with Indigenous communities, both virtually and in person, were continuously made, as were re-introduction meetings with new Chiefs and Councils. Meetings were held with five Indigenous communities to clarify the schedule of the Indigenous Knowledge Program, available funding, and how sensitive and confidential information would be collected and used. Several communities actively participated in the program (**Section 11.3.3**) and Indigenous Knowledge has been used to inform the Assessment Process.

Indigenous Communities Input and Information	How the Development of Milestones 1, 2, 3, and 4 Has Been Informed
• Consultation Methods on the Community Access Road: – Requests were made at community meetings by community members to update maps, including adding names of creeks and streams for legibility purposes and update locations of certain streams; – A few communities highlighted proper and engaged involvement with Marten Falls First Nation was required to receive community support for the Community Access Road; and – Consultation and engagement during the Draft Environmental Assessment / Impact Statement review period, including meeting availability and concerns regarding document translation availability.	• Updates to names on maps and locations of creeks and streams, along with updated locations of creeks, were made to maps and included in the Final Environmental Assessment / Impact Statement; • Efforts to engage with communities on an individual level were made and resulted in multiple Council-to-Council meetings, along with a Task Force between Marten Falls First Nation and Aroland First Nation. This Task Force was able to increase engagement with Aroland First Nation on the Community Access Road; and • Documents supporting the Draft Environmental Assessment / Impact Statement were made available in five languages, including English, French, Ojibway, Cree and Oji-Cree.

11.7.3 Consultation and Engagement with Interested Persons

Throughout the Assessment Process, several interested persons, including academics, local organizations, advisory committees, remote outfitters, trappers, and industry representatives, requested or participated in engagement activities related to the Community Access Road. These engagements occurred alongside broader public outreach described in **Section 11.5** and provided opportunities to discuss Project information, gather questions, and understand the interests of individuals and organizations with land- or resource-based connections in the region.

11.7.3.1 Email and Phone Outreach

Throughout the Assessment Process, the Project Team engaged interested persons through focused email and phone outreach. This outreach supported ongoing communication with individuals and organizations who expressed an interest in the Community Access Road or whose activities may intersect with the Community Access Road.

These methods supported timely distribution of notices, updates, and invitations to engagement activities such as Public Information Centres, webinars, field programs, and the review of the Draft Environmental Assessment / Impact Statement. Interested persons frequently contacted the Project Team by email or phone to request information, provide comments, ask questions about technical material, or seek clarification on timelines and next steps.

The Project Team responded to all inquiries, provided follow-up information, and offered meetings when appropriate. Email and phone correspondence also facilitated targeted outreach to businesses, non-governmental organizations, academic researchers, tourism operators, and members of the public. This consistent and ongoing outreach contributed to transparent communication and helped ensure that interested persons had accessible avenues to engage throughout the Assessment Process.

Broader outreach to mining, forestry, remote outfitter, and trapper groups occurred on October 1, 2024, November 13, 2024, and May 20, 2025, offering one-on-one or informal virtual meetings to discuss potential Project interactions with their operations and discuss potential mitigation measures. Additional calls to remote outfitters on August 8, 2025, resulted in conversations with two operators about the proposed route, potential business implications, and opportunities to provide comments during the Draft Environmental Assessment / Impact Statement review period. Information specific to mining, forestry, outfitter, and trappers is included in the Land and Resource Use

Technical Support Document (**Appendix U**) of the Final Environmental Assessment / Impact Statement.

11.7.3.2 Meetings and Event Participation

Several meetings and presentations were held with interested persons between 2024 and 2025, either at the request of individuals or through invitations extended to the Project Team.

On October 24, 2024, the Project Team met virtually with a Laurentian University professor, who provided a presentation on climate change projections, including information on precautionary approaches, Climate Atlas resources, and climate engagement tools relevant to northern communities.

In November 2024, the Project Team corresponded with Leuenberger Air Services Limited, who initiated contact to discuss concerns related to the Ogoki River crossing. The Project Team attempted to schedule a meeting and, on May 21, 2025, followed up again during the Draft Environmental Assessment / Impact Statement review period to invite Leuenberger Air to participate in consultation activities. As of September 5, 2025, no meeting had been scheduled.

Also in November 2024, the Project Team contacted Twin Lakes Outfitters to offer a meeting regarding their questions about river crossings. Twin Lakes Outfitters indicated they did not have availability to meet at that time, and no additional concerns were shared prior to September 5, 2025.

On November 20, 2024, the Project Team attended the Geraldton Area Natural Resources Advisory Committee fall general meeting as a guest presenter. The presentation provided an overview of the Community Access Road in advance of the Draft Environmental Assessment / Impact Statement, and committee members raised questions about tourism-related activity, access and ownership of the road, and availability of Preferred Route mapping. The Project Team offered an opportunity to meet again at Public Information Centre #6 in Geraldton or at another time convenient to the committee. The committee advised that attending Public Information Centre #6 would suffice. An invitation to attend Public Information Centre #6 was issued to Geraldton Area Natural Resources Advisory Committee.

In May 2024, the Greenstone Economic Development Corporation invited Chief Bruce Achneepineskum to speak at their general meeting. While the Chief confirmed availability, limited preparation time prevented the meeting from being added to the agenda. The Greenstone Economic Development Corporation expressed interest in scheduling a future engagement opportunity, though a date was not secured.

Between March 2 and 3, 2025, the Project Team presented at the Prospectors & Developers Association of Canada Conference, delivering two presentations on the Community Access Road and hosting an information booth to discuss the Community Access Road with conference participants.

11.7.3.3 Review Period of the Draft Environmental Assessment / Impact Statement

Consultation and engagement with interested persons during the Draft Environmental Assessment / Impact Statement review period occurred through the public release process, Public Information Centre #6, online access to the Draft Environmental Assessment / Impact Statement and Assessment Summary Package, and standard communication channels such as email and the Community Access Road website.

Interested persons were able to access the Draft Environmental Assessment / Impact Statement beginning April 22, 2025, and were invited to submit comments during a 60-day review period until June 23, 2025. The Assessment Summary Package was available at Public Information Centre #6, online via the Community Access Road website, and at selected public libraries as viewing locations.

A total of 10 comments were received from interested persons. Submissions were provided by Wildlife Conservation Society Canada, Andomoozwe Outfitters, Albany-Ogoki Outposts, and members of the public. These comments informed the preparation of the Final Environmental Assessment / Impact Statement and allowed the Project Team to incorporate input where possible in the Final Environmental Assessment / Impact Statement. The Record of Consultation and Engagement does not include formal comments submitted on the Draft Environmental Assessment / Impact Statement or responses to those comments. This information is, however, available in the Feedback and Response Log, available in **Appendix C**.

11.7.3.4 Summary of Issues and Feedback from Interested Persons

Input from interested persons spans several key phases of the Assessment Process, including feedback on data collection programs, mitigation strategies, permitting concerns, and potential impacts on local infrastructure.

Interested persons shared concerns about potential effects on fish and fish habitat, spawning areas, wildlife movement, ungulate populations, and how the road could affect hunting activity. They also provided comments related to cultural heritage, the importance of diversity in community well-being interviews, the Terms of Reference

approval process, and how the multiple road projects would be managed by provincial regulators. Input included concerns regarding cumulative effects and suggestions relating to the Project Inclusions List, including adding the KWG Railway Project. Additional feedback related to mapping, potential impacts on tourism outfitters and other businesses, safety concerns associated with traffic and road access, proximity of crossings to camps, and the location of the Ogoki River crossing. Interested persons also expressed perspectives on the duration of the Assessment Process, asked about the implications of the Impact Statement extension, and made suggestions related to Indigenous involvement.

The information provided by interested persons contributed to several aspects of the Assessment Process. Feedback informed fish and fish habitat evaluation, ungulate assessments, the cumulative effects assessment, and the Project Inclusions List. It supported refinements to mapping, contributed to route selection considerations, and was incorporated into land and resource use analyses, including tourism outfitter assessments and public safety considerations. Additionally, the feedback was reflected in assessment planning and responses to delays caused by external events, and in the extension of the Draft Environmental Assessment / Impact Statement review period.

Table 11-10 provides a high-level summary of input and information received from interested persons. The table outlines whether the information received informed the Assessment Process. While some feedback received directly informed the progression of each milestone or the overall Assessment Process, much of the input was broad, with limited details (which required ongoing follow-up for additional information from the commenters), or consisted of expressions of general interests or concerns.

Table 11-10: Summary of Input from Interested Persons and Influence on Milestones 1, 2, 3, and 4

Interested Persons Input and Information	How the Development of Milestones 1, 2, 3, and 4 Has Been Informed
• Concerns related to fish and fish habitat: – Several concerns were shared regarding bridge crossings and impacts to fish and fish habitat; – Concerns were raised fish spawning area; and – Concerns were raised about barriers to wildlife movement.	• Attachment B of the Fish and Fish Habitat Technical Support Document (**Appendix G**) details the results of the fish and fish habitat assessment. Attachment B includes the results of the quality of habitat, potential barriers to fish movements, and the fish sampling program; • The Environmental Assessment / Impact Statement outlines the methodology for completing the fish and fish habitat assessment (**Section 8.1.6**). This includes a review of existing information and field investigations that occurred between 2019 and 2022; • The Environmental Assessment / Impact Statement identifies the potential effects of the alternative routes on fish and fish habitat by evaluating potential effects to fish and fish habitat quantity and quality, use and access to habitat and migration, as well as survival, reproduction, and abundance (**Section 9.3.3**). This assessment also includes a review of potential effects from placing crossing structures on waterbodies and the potential effects from changing public access to recreational angling areas; • Measures and mitigation strategies have been designed to maintain existing environmental conditions to the extent possible with potential effects being minimized or avoided altogether; and • The potential effects and mitigation measures and monitoring strategies are identified in **Section 9.3.3.5**.
• Potential effects and mitigation measures related to ungulates: – Concerns were raised regarding the potential environmental impacts associated with increased hunting activity; and – Concerns were also raised about the potential effects of the Community Access Road on moose and caribou populations.	• The impacts to ungulate populations have been considered in the Ungulates Technical Support Document (**Appendix M**); • Throughout the Assessment Process various field studies have taken place to evaluate the impacts to ungulates including but not limited to tracking and aerial surveys, remote cameras, and caribou collaring which have informed the Final Environmental Assessment / Impact Statement; and • The Land and Resource Use Technical Support Document (**Appendix U**) provides information on remote outfitters, fishing, and hunting.
• Suggestions for additional Indigenous involvement: – It was suggested to involve more knowledge keepers in the Community Access Road.	• Decisions of the Project Team have been guided by Marten Falls First Nation, the Proponent of the Community Access Road. The Project Team regularly received guidance from community members, through both in-community and outside-of-community meetings, which helped inform decisions; • The Project Team has received Indigenous Knowledge from certain Indigenous communities to understand Aboriginal and / or Treaty Rights and Interests related to the Community Access Road. Indigenous Knowledge as well as information on Indigenous land and resource use and cultural practices has helped the Project Team better understand and appreciate the environment with respect to the identity, culture, and heritage of Indigenous communities. Indigenous Knowledge or guidance provided through meetings, emails, surveys, and focus groups was considered in the Technical Support Documents (**Table 3-1**), where available. The Indigenous Knowledge received to date has been woven with scientific approaches, and both knowledge systems have been given equal consideration in forming the foundation for existing conditions, predicting potential project effects, and determining appropriate mitigation and monitoring methods; and • Nine Indigenous communities provided comments on the Draft Environmental Assessment / Impact Statement, comments and responses to the feedback received on the Draft Environmental Assessment / Impact Statement, including how each was considered, is documented in a Feedback and Response Log in **Appendix C**.
• Considerations for Cultural Heritage and Aboriginal and / or Treaty Rights and Interests: – It was suggested to include a diverse sample of interviews related to understanding how Aboriginal and / or Treaty Rights and Interests and community well-being (human health, social, and economics) impacts are considered.	• The community well-being information (socio-community and health) collected targeted subgroups, including women, youth, and Elders, through focus groups and interviews. A total of 10 interviews were conducted with community members, and 10 individuals attended the focus group, including 7 youth. Support was also offered for those needing assistance (for example, to complete surveys).

Interested Persons Input and Information	How the Development of Milestones 1, 2, 3, and 4 Has Been Informed
• Concerns and suggestions regarding provincial involvement and other projects: – Concern was noted regarding the Terms of Reference approval process and lack of Indigenous recognition; and – Concern was noted regarding how the Ministry of the Conservation, Environment and Parks will manage three road projects at the same time.	• The Project Team has acted with input, guidance, and direction from the Marten Falls First Nation Chief and Council. In addition to federal and provincial regulations, the Community Access Road has met Marten Falls First Nation requirements. To meet the provincial requirements, the Project Team prepared a Terms of Reference in accordance with the provincial *Environmental Assessment Act* (Government of Ontario, 1990a). While the 1990 version of the Act is the overarching regulation, amendments are made from time to time and the Terms of Reference was developed in accordance with the regulations in place at the time of submission, and the environmental assessment was developed in accordance with updates in place at the time of submission. Additionally, the Project Team has identified 31 Indigenous communities, Tribal Councils, and Provincial / Territorial Organizations that have the potential to be impacted by the Community Access Road. These groups have been, and will continue to be, consulted and engaged on activities related to the Community Access Road and have been encouraged to share feedback on the Assessment Process; and • It was recommended to contact Government of Ontario and the Agency directly with any concerns regarding their ability to manage the other road projects.
• Concerns and feedback regarding cumulative effects, including the Project Inclusions List: – 1 comment included concerns regarding impacts from Ontario Power Generation on water and fish in the Albany and Ogoki Rivers and noted that water levels being studied need to acknowledge the impacts of diversions and flow levels from dams. It was also noted that although it is not the primary focus of the Community Access Road, Ontario Power Generation may have a greater effect on the environment than the bridges and roads studied as part of the Community Access Road. It was also mentioned that cumulative effects may occur, but impacts from Ontario Power Generation are already occurring; and – Comments were made regarding interest on the cumulative effects Project Inclusions List. A suggestion was made to include the KWG Railway Project in the Project Inclusions List.	• Various sources of information, including Ontario Power Generation reports were reviewed [Section 5.1.2.2 of the Surface Water Technical Support Document (**Appendix F**)]. A water control dam (Waboose Diversion Dam) was identified in the Surface Water Technical Support Document (**Appendix F**) as affecting river flows within the existing conditions Regional Study Area [Section 5.1.2.2 of the Surface Water Technical Support Document (**Appendix F**)]. The Community Access Road included the Ogoki and Long Lac water diversion existing infrastructure as part of the cumulative effects assessment for surface water (**Section 10.2.2**); and • The comment was noted, and the KWG Railway Project was considered for inclusion. The KWG Railway Project is included in the Project Inclusions List in **Section 10**.
• Suggestions for map additions – There were two suggestions for additions to maps provided at public meetings: an outfitters company on Brace Lake and a well location on Marten Falls First Nation reserve.	• Planning for the groundwater and geochemistry program took 2 years and included direct conversations and site visits with representatives from Marten Falls First Nation and Aroland First Nation to review areas of sensitive use. Feedback on well locations, as well as any other information, was encouraged to assist with planning future field programs. The water supply well location has been added to Figure 4-3 in the Groundwater Technical Support Document (**Appendix H**); and • Outfitters were contacted as part of the Land and Resource Use Technical Support Document. Brace Lake Outfitters was contacted but did not engage [Section 4.3.2 of the Land and Resource Use Technical Support Document (**Appendix U)**] Brace Lake (camp) was not identified to be potentially impacted by the Community Access Road.
• Concerns about impacts to businesses: – Concerns related to businesses, including whether businesses negatively affected by the built Community Access Road would be purchased, and general concerns around how the Community Access Road could affect businesses, specifically tourism outfitters.	• Various factors, including the location of outfitters were considered in the selection of the Preferred Route for the Community Access Road (**Section 4**). The analysis of factors considering outfitters concluded that from the alternatives being evaluated the Preferred Route would have a lower net effect on the attractiveness of the area for remote tourism operations (**Appendix A**); • Section 7.2.3 of the Land and Resource Use Technical Support Document **(Appendix U)** indicates that the Community Access Road could provide new recreation and tourism opportunities. However, construction and operations of the Community Access Road may result in disruption to existing activities due to changes in noise, vibration, air quality and views. The Community Access Road may also affect species that are hunted or fished for recreational purposes. The outfitter camps that are in proximity to the road have been identified and assessed as part of the Land and Resource Use valued component; and • As well, as part of the assessment, mitigation has been recommended to avoid and / or minimize the predicted effects [Section 7 of the Land and Resource Use Technical Support Document (**Appendix U**)]. This could include measures to minimize effects that could disturb operations of existing tourism outfitters, or as part of design development of alternative route alignments and watercourse crossing locations.

Interested Persons Input and Information	How the Development of Milestones 1, 2, 3, and 4 Has Been Informed
• Support for Impact Statement extension and request for more information: – General support for the Impact Statement extension request was communicated; and – It was also requested to understand if data collection was impacted with revised timelines due to the Impact Statement extension.	• The Impact Statement Phase Extension Request Work Plan (AECOM, 2022b) was influenced by delays resulting from the COVID 19 pandemic, summer 2021 forest fires, winter 2021 / 2022 heavy snow conditions and unforeseen regulatory requirements. These resulted in delays to field programs.
• Concerns regarding traffic and road safety: – Concerns related to safety due to increased traffic, potential new traffic crossings and location of the Community Access Road entering the Marten Falls First Nation community.	• Intersections of the Community Access Road with southern networks have been assessed and reviewed; signage in the form of advance notification and potential STOP conditions may be incorporated. Clear zone on inside of curves (additional tree clearing) may be enhanced for site lines. From a maintenance safety factor dust suppressant may be used in select areas; • Different routing options have been explored, such as along the river versus coming in from the north of Marten Falls by the airport). Safety considerations that were included in the route selection process included temporary and permanent impacts to watercourses used for traditional transportation and increased traffic through the Marten Falls First Nation community. Marten Falls First Nation had chosen the options further away from the Albany River and coming from the north; and • Various factors, including public safety were considered in the selection of the Preferred Route for the Community Access Road (**Section 4**). The analysis of public safety factors specifically considered road use accidents as an indicator (**Appendix A**) and concluded that all alternatives had relatively equal potential for accidents. The potential for public safety effects from the Community Access Road have been assessed in the Community Well-Being Technical Support Document (**Appendix T**).
• Community Access Road timelines: – Concerns that the Community Access Road Assessment Process is taking too long.	• The Project Team advised that the provincial environmental assessment is a long process due to the size of the Community Access Road. The COVID-19 pandemic, summer 2021 forest fires, winter 2021 / 2022 heavy snow conditions and unforeseen regulatory requirements also impacted timelines and caused delays, especially to field programs; and • The review period for the Draft Environmental Assessment / Impact Statement was extended from June 23, 2025, to September 5, 2025, due to requests for extensions from Indigenous communities and government regulators.
• Information regarding Community Access Road access, engineering and design: – Concerns related to the general public's access and use of the Community Access Road; – Concerns about traffic; – Concerns regarding proximity of river crossings to camps; and – Concerns about Ogoki River crossing.	• Information on traffic can be found in **Appendix W**; • The Preferred Route was selected based on feedback received from Indigenous communities and interested persons. Information on the Preferred Route is available in **Section 4.4**; • **Section 4.4.1** contains information on Segment 1 – Ogoki Crossing; and • Information on bridge construction can be found in **Section 7.2.3.5**.

11.7.4 Consultation and Engagement with Government Agencies

Table 11-11 provides a high-level summary of input and information received from government agencies. The table outlines whether the information received informed the Assessment Process. While some feedback received directly informed the progression of each milestone or the overall Assessment Process, much of the input was broad, with limited details (which required ongoing follow-up for additional information from the commenters), or consisted of expressions of general interests or concerns.

Table 11-11: Summary of Input from Government Agencies and Influence on Milestones 1, 2, 3, and 4

Government Input and Information	How the Development of Milestones 1, 2, 3 and 4 Has Been Informed
• Environmental Assessment methodology and study plan comments: – Feedback was provided on the study plans and the Environmental Assessment methodology across all the valued components assessed in the Environmental Assessment / Impact Statement.	• Supporting Technical Documents were prepared by each technical discipline and are appended. Each includes information on how comments received on associated study plans were used to inform assessment methodology or their specific scope and studies. The Supporting Technical Documents also describe deviations from recommendations and the reasoning behind this, if applicable.
• Eastern Migratory Caribou mitigation: – Feedback was provided on the need for tailored strategies for Eastern Migratory Caribou compared to Boreal Caribou.	• The Environmental Assessment / Impact Statement includes tailored mitigation strategies for Boreal Caribou and Eastern Migratory Caribou: – The mitigation strategies account for the distinct sensitivities of each species to disturbances, with specific life history considerations factored into the plans (**Section 9.4.5.5**); and – Feedback on caribou habitats has directly influenced site-specific measures in wildlife management (**Section 9.4.5.5**).
• Sensitive Data License Agreement and caribou collaring: – Requests were made to extend timelines for caribou collaring data and amend the sensitive data license agreement.	• A Sensitive Data License Agreement has been used to maintain confidentiality measures for sensitive caribou data. The agreement has been amended with ongoing discussions with relevant ministries to help ensure compliance with the *Endangered Species Act* and data protection requirements (Government of Ontario, 2007); and • Caribou collaring programs were conducted between April 2020 and March 2024, to identify caribou movement throughout the study area. The caribou collaring program was extended due to collars not falling off automatically; this is not unusual due to the technology used. Additionally, the collars could not be manually removed in 2024 as there was not enough snow to safely remove the collars from the caribou.
• Timeline extension: – A request was made for a timeline extension due to the impacts of extreme weather, COVID-19, and other challenges.	• The Environmental Assessment / Impact Statement describes timeline extensions: – A detailed explanation of how COVID-19, summer 2021 forest fires, winter 2021 / 2022 heavy snow conditions, and unforeseen regulatory requirements impacted the timeline is included in **Section 5.1.2**. As a result of these challenges, a timeline extension request was submitted to the Agency.
• Deviations from the Tailored Impact Statement Guidelines: – Concerns were expressed about deviations from the Tailored Impact Statement Guidelines in the study plans.	• The Technical Support Documents conform with the Tailored Impact Statement Guidelines: – They provide detailed rationales for deviations when necessary, providing transparency and alignment with regulatory expectations (Section 8 of the Technical Support Document for each valued component); and – Feedback from the Identification of Preferred Alternatives was used to fine-tune cumulative effects assessment methods (Section 9 of the Technical Support Document for each valued component).
• Economic impact assessments: – Support was requested from the Ministry of Transportation to assess economic impacts and address concerns regarding the economic valued components.	• The Community Well-Being Technical Support Document (**Appendix T)** incorporates economic impact assessments: – Support from the Ministry of Transportation was secured to assist in evaluating the effects on the economic valued components [Community Well-Being Technical Support Document; (**Appendix T**)]; and – Specific feedback on economic concerns has been incorporated into the Community Well-Being Technical Support Document (**Appendix T**). Recommendations for mitigation measures and monitoring opportunities are included in Sections 7, 8 and 9 of the Community Well-Being Technical Support Document (**Appendix T**)**.**
• Municipality of Greenstone Road Impacts: – Concerns were raised by the Municipality of Greenstone regarding potential negative impacts on local roads due to the Community Access Road.	• The Community Well-Being Technical Support Document (**Appendix T**) addresses feedback from the Municipality of Greenstone: – Potential impacts on local roads due to the Community Access Road-related vehicle activity are included in the Community Well-Being Technical Support Document (**Appendix T**). Changes to road use and traffic volumes on existing road infrastructures have been identified as an impact. Additional consultation will occur throughout the remaining milestones, along with continued examination of road maintenance and mitigation strategies.
• Permitting issues and hydrological programs: – The Ministry of the Environment, Conservation and Parks raised concerns about permitting issues and timelines for the hydrological field programs.	• The Surface Water Technical Support Document (**Appendix F**) addresses permitting issues raised by the Ministry of the Environment, Conservation and Parks: – The study plan review process was updated to include provincial for future hydrological monitoring programs; and – Revised timelines and permitting submissions were implemented based on feedback from hydrological program consultations.
• Cumulative effects project inclusion list: – The Ministry of Natural Resources suggested Wataynikeneyap Powerline should be included in the cumulative effects assessment.	• The Environmental Assessment / Impact Statement includes a cumulative effects assessment that considers reasonably foreseeable future projects within the study area: – Wataynikeneyap Powerline has been included for consideration in the cumulative effects assessment by the relevant valued components.

Government Input and Information	How the Development of Milestones 1, 2, 3 and 4 Has Been Informed
• Groundwater program delays and draft assessment with 1 year of groundwater data: – The Agency requested clarification related to the proposed approach to submit a Draft Environmental Assessment / Impact Statement based on 1 year of groundwater data – The Agency requested confirmation of the hydrograph period to be presented, identification of which groundwater and peatlands program elements would be delayed, and a description of how the draft dataset differs from the approach previously deemed acceptable by the Federal Review Team.	• Groundwater assessment approach and supporting documentation were refined based on Agency and technical review input regarding delayed field program elements and the 1-year dataset basis: – The assessment describes the modified groundwater data collection approach and clearly differentiates the 1-year dataset basis from the previously accepted approach, including clarification of hydrograph coverage and delayed program elements; and – Monitoring methods and terminology were clarified based on Agency questions (for example, hydrographs based on datalogger-equipped wells and “monitoring events” as planned site visits for logger downloads and sampling), with confirmation that Natural Resources Canada’s groundwater expert reviewed the approach and deemed it acceptable (March 22, 2023).
• Issues with maps (Consultation Methods): – It was noted by the Ministry of Energy and Mines that viewing maps should include the names of creeks and streams for legibility, including Marten Falls (the actual falls) and Wabassi Lake, and that Calbert Creek was shown in the wrong location.	• The Environmental Assessment / Impact Statement reflects community feedback on map legibility and accuracy: – Feedback from the May 28, 2025, Marten Falls First Nation community meeting informed updates to mapping presented in the Environmental Assessment / Impact Statement to improve legibility (addition of key creek / stream and feature names, including Marten Falls and Wabassi Lake) and to correct the location of Calbert Creek.
• Wildlife Scientific Collector’s Authorization for wolverine work (Field Studies, Wildlife, Trap Lines): – The Ministry of Natural Resources and Forestry provided direction on authorization requirements for wolverine hair snag surveys, including authorization duration and coverage requirements. – The ministry advised the Wildlife Scientific Collector’s Authorization can only be issued for a 1-year period, must be in place for both collection periods and while samples are at the lab due to reporting requirements, and requested a ministry-issued letter to licensed trappers describing the program, potential implications, and Project Consultant contact information.	• The Environmental Assessment / Impact Statement reflects ministry direction on permitting scope and trapline communications for the wolverine program: – Ministry direction informed the permitting approach for the wolverine field program, including ensuring authorization coverage aligns with collection timing and reporting conditions (including the period when samples are at the lab); and – Ministry input informed how trapline engagement and communications were carried out and documented, including provision of program details and points of contact to licensed trappers to support awareness and coordination.
• Overlapping License Agreement and *Crown Forest Sustainability Act* -exempt Forest Resource License (Provincial Permit): – The Ministry of Natural Resources and Forestry advised that Crown Forest Sustainability Act–exempt Forest Resource Licensing operates on a fiscal year basis (April 1 to March 31), with issued licences valid for 1 fiscal year, and suggested revising the Overlapping License Agreement term to align with the fiscal year-based licensing system (for example, January 1, 2022, to March 31, 2023). – The Ministry of Natural Resources and Forestry confirmed prerequisites for tree clearing authorization (for example, Letter of Authority and Land Use Permit) and directed coordination on the Overlapping License Agreement to support tree clearing for the groundwater monitoring drilling program.	• The Environmental Assessment / Impact Statement reflects ministry direction on authorizations sequencing and fiscal-year alignment for tree clearing permits: – Ministry input informed the sequencing and documentation of provincial authorizations required for tree clearing, including prerequisites identified by the Ministry of Natural Resources and Forestry and the fiscal year-based validity of forest resource licences exempt under the Crown Forest Sustainability Act; and – The Environmental Assessment / Impact Statement includes the Crown Forest Sustainability Act–exempt Forest Resource Licence and the Permit to Remove in the authorizations list, consistent with the permitting approach used to support the groundwater monitoring drilling program.

11.8 Considerations of Identity and Gender-Based Analysis Plus

The *Impact Assessment Act* requires Gender-Based Analysis Plus to be applied to impact assessments in Canada. Gender-Based Analysis Plus is not a specific method but an adaptable approach that assesses inequalities and impacts of policies, programs, and projects on diverse groups and intersecting identities (for example, gender, sexual orientation, age, race, ethnicity, class, religion, and mental or physical disability) (Women and Gender Equality Canada, 2024). This approach supports understanding of socio-cultural and historical contexts, including those shaped by colonization.

As the Community Access Road is led by Marten Falls First Nation and involves extensive Indigenous engagement, a Gender-Based Analysis Plus lens has been incorporated throughout consultation and engagement activities. This approach underscores the importance of considering diverse needs and perspectives within the communities participating.

Efforts to respect and incorporate Indigenous Knowledge are reflected in the guiding principles (see reference to the Terms of Reference Consultation Plan in **Section 11.2.2**). The first-person voice of Marten Falls First Nation in **Section 1**, Our Story, places their experience, sovereignty, and cultural values at the forefront. Gender-Based Analysis Plus considerations are further described and included in **Section 6.2** of the Final Environmental Assessment / Impact Statement and supporting Technical Support Documents.

To fulfill requirements of the *Impact Assessment Act*, the Consultation and Engagement Program made efforts to consider a range of perspectives from marginalized, vulnerable, and / or at-risk sub-populations who often experience inequality and barriers. This included making efforts where possible to provide opportunities for engagement with:

- Indigenous peoples;
- Visible minorities;
- Women;
- Youth;
- Elders;
- Members of the Two-Spirit, Lesbian, Gay, Bisexual, Transgender, Queer, Questioning, Intersex, and Asexual community;

- Indigenous activity-based subgroup (for example, hunter, trapper, fishermen);
- Non-Indigenous activity-based subgroups (for example, recreationalists, snowmobilers, outfitters, tourism establishment operators); and
- People with disabilities.

Marten Falls First Nation also consulted and engaged other subgroups identified by communities during consultation and engagement. The information from these activities was considered by applicable disciplines for the purposes of data collection and consideration of disproportionate effects. More detailed information about the Community Access Road's Gender-Based Analysis Plus study is in **Section 6.2**.

The Consultation and Engagement Program included opportunities to hear from a diverse range of perspectives from interested communities and their members, including subgroups, identified in the Agency's Indigenous Engagement Partnership Plan and the Public Participation Plan. The following consultation and engagement approaches and activities include a Gender-Based Analysis Plus framework:

Guiding Principles:

- The guiding principles adopted for the Assessment Process encourage multiple and ongoing opportunities for dialogue, including participation of relevant self-identified subgroups (for example, women, youth, Elders). They also demonstrate an effort to incorporate Indigenous ways of being and knowing into the plan that guided consultation and engagement on the Community Access Road.

In-person Community Meetings:

- Where possible, meetings, activities and workshops were hosted in Marten Falls or neighbouring Indigenous communities, providing women, Elders, youth, and other community members and land users the opportunity to be in place when discussing the Community Access Road;
- During the Marten Falls First Nation member meeting December 6, 2022 (for Public Information Centre #4), youth commented that they would be more enticed to join meetings if door prizes included items like gift cards (for example, Walmart) or if larger prizes, like cell phones, were offered. These suggestions were applied to future meetings and advertised in notices to community members;

- Community Access Road branded colouring pages were provided for children at community and public meetings to allow attending families to participate in the meetings and for youth participation; and
- During the May 2025 Marten Falls First Nation and Aroland First Nation member meetings, a Story Beads exercise was held to create a space for intergenerational dialogue and shared storytelling using beadwork as a metaphor. Marten Falls First Nation and Aroland members shared their hopes and concerns around the Community Access Road including increased access to food and reduced costs of living, along with concerns about outsider access and substance abuse.

Accessibility for Attending Meetings:

- Private car service was offered to improve accessibility for Marten Falls First Nation and Aroland First Nation community members to attend community meetings in Thunder Bay.
- Private shuttle service to the Public Information Centres held in Geraldton, Ontario were offered to neighbouring Long Lake #58 and Ginoogaming First Nations. There was no expressed interest in the offer until Public Information Centre #6, when Long Lake #58 hired their own shuttle; the cost of the service was paid by the Project Team. The shuttle facilitated attendance of Elders at the meeting.

Youth Participation:

- In November 2021, a youth engagement program was delivered in Marten Falls. The program had different activities separated by age groups (Kindergarten to grade 2; grades 3 to 5; grades 6 to 8; and grade 9+ / post-secondary). Activities focused on continuing awareness, excitement, education and pride about the Community Access Road. Discussion was encouraged and opportunities to learn about science, technology, and engineering and math careers were provided;
- On June 20, 2023, a youth engagement program for Marten Falls First Nation youth living outside of the Community was held as part of the Socio-Community Study (**Appendix T**). The purpose of the youth engagement program was to encourage Marten Falls First Nation youth to participate in decisions that will affect them in the future, and to acknowledge their unique perspective;
- An in-community meeting was held in Marten Falls on July 16, 2024. Summer is a time when high school-aged youth are out of school and in the community; this timing allowed youth to attend and learn about the Community Access Road;

- In July and August 2024, Marten Falls First Nation youth were financially compensated to participate in the review of Sections 1 through 4 of the Draft Environmental Assessment / Impact Statement (Our Story, Why We Need This Road, Our Roles, and How We Selected Our Road) in advance of the release; and
- In October 2024, Marten Falls First Nation youth were invited to participate in a Sharing Circle hosted by the Marten Falls First Nation Community Coordinator at community-specific meetings in Thunder Bay and Marten Falls First Nation, respectively. Financial compensation was offered to participants; however, no registrations were received.

Women Participation:

- In October 2024, Marten Falls First Nation women were invited to participate in a Sharing Circle hosted by the Marten Falls First Nation Community Coordinator at community-specific meetings in Thunder Bay and Marten Falls First Nation members, respectively. Financial compensation was offered to participants; however, no registrations were received.

Financial Opportunities for Subgroups:

- Opportunities were provided to specific Indigenous communities to hire Community Coordinators; two women were hired as Marten Falls First Nation Community Coordinators; and
- Young Marten Falls First Nation members (18+), including over 11 women, were hired as field program support staff.

Valuable Elder Knowledge:

- Meetings were held with Elders from Long Lake #58 First Nation on November 10, 2023, and June 20, 2024, to receive updates on the Community Access Road, including the preliminary technically preferred route. A group of Elders from Long Lake #58 also attended Public Information Centre #6 in Geraldton, speaking with Project Team Consultants and the Marten Falls First Nation Community Access Road Senior Advisor;
- On June 11, 2024, Elders participated in a one-day Elders gathering at the Three-Road Project Gathering and Expo; and
- In July and August 2024, Marten Falls First Nation Elders (including women) participated in review sessions for Sections 1 through 4 of the Draft Environmental Assessment / Impact Statement (Our Story, Why We Need This Road, Our Roles, and How We Selected Our Road), in advance of the release; they were financially compensated for their efforts.

Virtual Opportunities:

- Opportunities were provided for people to participate in webinars from outside of the community (youth) or from their homes, including providing feedback via online surveys. Of note, at a Marten Falls First Nation meeting on February 2, 2022, a community member noted their 16-year-old watched the zoom meeting and was very interested.

Youth Preferences for Communication:

- During the Marten Falls First Nation meeting on December 6, 2022, in advance of Public Information Centre #4, youth attended and mentioned that the Facebook group was the best way to receive information, and that in-community events do not really work for them as they are often away at school. As a result, the Marten Falls First Nation Community Coordinators made sure content was posted on the private Marten Falls First Nation Facebook page; and
- Based on demographic reach and feedback received, Instagram and LinkedIn profiles were created for the Community Access Road in March 2024 to provide updates to youth and Indigenous professionals online.

The following are challenges observed with Gender-Based Analysis Plus in relation to the Community Access Road:

- Marten Falls First Nation youth typically were not able to attend in-community events as they attend high school outside of the Community; however, by scheduling in-community meetings during the summer, there was an increase in youth participation;
- A comment was received at Public Information Centre #3 noting Marten Falls First Nation members' interest in trapping and community events are not as popular as before. Youth do not seem to have interest in these activities;
- Signing in at meetings and engagement events (Public Information Centres) is optional, so there is not always a true representation available of those who identify as part of a subgroup; and
- The subgroups including, but not limited to, Lesbian, Gay, Bisexual, Transgender, Queer, Questioning, Intersex, Asexual and Two-spirited individuals may be unwilling / uncomfortable to self-identify.

11.9 Consultation and Engagement After Milestone 4 up to Final Submission

As previously noted, the reporting period of the Record of Consultation and Engagement ends at the completion of Milestone 4 (September 5, 2025). Consultation and engagement activities, however, occurred after the end of this reporting period but before the submission of the Final Environmental Assessment / Impact Statement. These are activities—occurring between September 6, 2025, up to February 13, 2026—are described below to demonstrate advancements in consultation and engagement efforts. Descriptions of upcoming activities and opportunities for consultation and engagement after submission of the Final Environmental Assessment / Impact Statement is provided in **Section 11.10.**

11.9.1 Public Information Centre #7 (Virtual)

Notification: Notification of Public Information Centre #7 was provided through an email distributed on January 27, 2026, website notifications and social media posts.

Dates and Locations: Virtually on February 4, 2026.

Objectives and Topics: Public Information Centre #7 focused on the release of the Final Environmental Assessment / Impact Statement. Information presented included: an overview of the Assessment Process; the selection of the Preferred Route; feedback received on the Draft Environmental Assessment / Impact Statement; and the Final Environmental Assessment / Impact Statement review process. The presentation was pre-recorded and uploaded to the Community Access Road website on the same day as the Public Information Centre to allow those who were unable to attend the live session the opportunity to view it at their convenience.

Attendees: A total of 31 individuals registered for the Public Information Centre #7, and approximately 22 participants attended. Attendees represented a broad cross-section of audiences, including community members and / or representatives from six different Indigenous communities, federal and provincial government agencies, interested persons, environmental organizations, and industry representatives.

Feedback: A Question and answer period with the Project Team members followed the pre-recorded presentation. Key question and comment themes reflected a range of interests which included job opportunities and access to job information, construction timelines, the Final Environmental Assessment / Impact Statement review process and timeline, Community Access Road governance, maintenance, and monitoring, Aboriginal and / or Treaty Rights and Interests feedback and summary document, access and security, and river crossings.

11.9.2 Meetings

The following meetings were held with Indigenous communities, Marten Falls First Nation, and interested persons to help prepare for the release of the Final Environmental Assessment / Impact Statement.

Meetings with Indigenous Communities

A series of meetings took place to support Public Information Centre #7, including hybrid meetings with Marten Falls First Nation on February 3 and 4, 2026, in Thunder Bay and Marten Falls, respectively. A virtual meeting was also held for Aroland First Nation on February 4, 2026, however, due to a tragedy in the community no one was able to attend.

At each meeting, a presentation provided: an overview of the Assessment Process; the selection of the Preferred Route; feedback received on the Draft Environmental Assessment / Impact Statement; and the Final Environmental Assessment / Impact Statement review process. Following each presentation, a question and answer period was hosted.

On January 26, 2026, the Project Team provided a presentation to Mushkegowuk Council. The presentation provided an overview of the Community Access Road and the Assessment Process. Information was also provided on the selection of the Preferred Route and release of the Final Environmental Assessment / Impact Statement.

Meetings with Interested Persons

On October 21, 2025, the Project Team met with Wildlife Conservation Society Canada to discuss wolverine denning habitat, caribou habitat, mitigation hierarchy, and monitoring and survey techniques. The Project Team noted that the caribou and wolverine effects assessments include an evaluation of aerial surveys, discussion of mitigation and monitoring approaches, and consideration of cumulative effects.

Meetings with Government Agencies

A series of meetings and communications were undertaken with government agencies to support review of the Draft Environmental Assessment / Impact Statement and to clarify next steps in the Assessment Process. These activities included an interagency meeting and follow-up discussions with the Ministry of Natural Resources and the Species at Risk Branch regarding comments received on October 17, 2025. Meetings were also held with the Ministry of the Environment, Conservation and Parks to discuss questions arising from feedback on the Draft Environmental Assessment / Impact

Statement, and the proposed submission plan for the Final Environmental Assessment / Impact Statement including anticipated next steps and overall process.

In addition, the Project Team shared the Progress Report 4 Introduction and the Aboriginal and / or Treaty Rights and Interests Summary Report with the Impact Assessment Agency of Canada to support preparation of the Impact Statement.

11.9.3 Other Communication Activities

Communication activities also occurred during this period. Monthly E-blasts continued to be distributed to the contact list with supporting updates provided via social media. A video—Why the Road to Marten Falls—was also released on social media channels sharing the benefits of the Community Access Road for Marten Falls. These include a lower cost of living, increased housing, a positive effect on mental health, and freedom to travel for community members. Targeted emails continued to be sent to each Indigenous community's group of key contacts to follow up on ongoing conversations and provide updates on the Final Environmental Assessment / Impact Statement.

A Fall Field Notice was distributed on September 16, 2025, via email and posted on the website. The field notice included updates on the groundwater well decommissioning, geotechnical investigation, and SkyTEM geophysical survey field programs which were scheduled to take place in fall 2025. On September 23, 2025, an additional field notice was distributed via email and posted on the website to provide further information on the SkyTEM geophysical survey that was planned to take place in fall 2025. A Geotechnical Investigation Field Notice was distributed on November 10, 2025, via email and posted on the website. The field notice included information on the geotechnical investigation program, which was planned for November and December 2025. In consideration of feedback from Indigenous communities, the field work was postponed to avoid winter hunting activities.

Progress Report 4 was distributed to Indigenous communities for review on January 16, 2026; communities were asked to provide their feedback by February 2, 2026, noting that they could also provide comments during the public review process of the Final Environmental Assessment / Impact Statement. An extension to February 13, 2026, was granted for two communities who requested more time to review their individual report. Feedback was provided by one community and was considered in the Final Environmental Assessment / Impact Statement.

The Stage 2 Archaeological Assessment Report was also released to Indigenous communities for review on January 16, 2026, with feedback requested by February 18, 2026. Any feedback received will be considered in the detail design of the Community Access Road.

11.9.4 Notice of Environmental Assessment Availability

The Ministry of the Environment, Conservation and Parks requires a notice of Environmental Assessment availability to be electronically distributed 2 weeks in advance of the Notice of Submission. On February 6, 2026, the Project Team sent an advance notice of availability and upcoming Notice of Submission email to the contact list. The email was intended to help people plan for the upcoming review period and be informed about next steps. The Notice of Submission was attached, including information on the formal publication on February 20, 2026.

11.10 Ongoing and Future Consultation and Engagement

Activities that occurred on and shortly after submission of the Final Environmental Assessment / Impact Statement, February 20, 2026, are summarized below.

11.10.1 Notice of Submission

The Notice of Submission is a formal public notice issued when a Project Proponent submits a completed environmental assessment to the Ministry of the Environment, Conservation and Parks. The Notice of Submission for the Community Access Road is distributed to the Community Access Road contact list, posted on the Community Access Road website, and advertised in newspapers. The notice provides information on the Assessment Process, where to access the Environmental Assessment / Impact Statement, in-person viewing locations for the Assessment Summary Package, the review period length, and how to provide comments.

11.10.2 Assessment Summary Package

An Assessment Summary is provided to support the review of the Final Environmental Assessment / Impact Statement. This includes the Chief's letter, an executive summary, plain-language summaries of information contained in the Final Environmental Assessment / Impact Statement and associated Technical Support Documents, and frequently asked questions. The information in the Assessment Summary Package will be available online including translations in Ojibway, Oji-Cree, Cree, and French.

11.10.3 Comments on the Final Environmental Assessment / Impact Statement

Proponent-led consultation and engagement officially ends with submission of the Final Environmental Assessment / Impact Statement to the regulators. Consultation and engagement during the review of the Final Environmental Assessment / Impact Statement is undertaken by the federal and provincial agencies. The Proponent, however, will support the regulators in responding to comments on the Final Environmental Assessment / Impact Statement, including attending meetings, to support the comment period for the Final Environmental Assessment / Impact Statement.

11.10.4 Release of Community-Specific Aboriginal and / or Treaty Rights and Interests: Final Impact Assessment Reports

Following the release of the Draft Environmental Assessment / Impact Statement, community-specific Draft Aboriginal and / or Treaty Rights and Interests: Draft Impact Assessment Reports (Draft Reports) were issued to Indigenous communities through June and July, 2025. The Draft Reports included information from publicly available sources, as well as any Indigenous Knowledge Reports received from communities before January 2025. The reports outlined the assessment process for Aboriginal and / or Treaty Rights and Interests related to the Community Access Road. Indigenous communities had 90 days to review and provide feedback on the Draft Reports. The Final Aboriginal and / or Treaty Rights and Interests: Impact Assessment Reports will be issued to individual communities following the submission of the Final Environmental Assessment / Impact Assessment.

11.10.5 Release of Country Foods and Water Use Assessment Report

The Community Well-Being Team conducted a Country Foods Program where community members from Aroland First Nation and Marten Falls provided samples of foods that were hunted, fished, or gathered from the land and water—including walleye, moose, goose, beaver, and blueberries—to assess existing contaminant levels in traditional food species commonly harvested and consumed in the community. These species were selected based on conversations with Marten Falls First Nation Senior Community Advisors and the Marten Falls First Nation Community Coordinator. Samples were accepted at the May 2025 meetings with Aroland First Nation and Marten

Falls First Nation members. These samples were used to understand which contaminants may currently be present in local foods and water, and will serve as a baseline from before the Community Access Road is built. These reports will be made available to Aroland First Nation and Marten Falls First Nation following the release of the Final Environmental Assessment / Impact Statement.

In addition, a team of two Marten Falls First Nation Community Access Road Project Consultants and a Marten Falls First Nation member visited various sites in the Community to retrieve water samples. Water samples were taken from the Albany River near the water treatment plant and at the dock where people are known to swim. The Marten Falls First Nation member recommended sampling sites based on where members are known to swim or collect water for drinking. The results will be shared with the Community following the release of the Final Environmental Assessment / Impact Statement.

11.10.6 Cultural Heritage Reports

The Draft Cultural Heritage Evaluation Report will be made available to Indigenous communities for review and comment before finalization.

11.10.7 Meetings with Neighbouring Indigenous Communities

Indigenous communities have expressed interest in meetings to support their review of the Final Environmental Assessment / Impact Statement and build relationships as the Community Access Road moves into the next phase. It is anticipated that additional meeting requests will be made following submission of the Final Environmental Assessment / Impact Statement. These will be responded to and facilitated by the federal and provincial government.

11.10.8 Meetings with Interested Persons

Ongoing engagement with local outfitters is expected to continue through this next phase of the Assessment Process for the Community Access Road. A meeting with a local outfitter was being planned during preparation of the Final Environmental Assessment / Impact Statement. The date, however, was not yet finalized and the meeting is expected to take place shortly after the release of the Final Environmental Assessment / Impact Statement.

The Project Team will also attend the 2026 Prospectors & Developers Association of Canada Conference from March 1 to 4, 2026.

11.10.9 Other

A Final Environmental Assessment / Impact Statement video will be posted to accompany the submission of the Final Environmental Assessment / Impact Statement. It will provide a summary of what is included in the Final Environmental Assessment / Impact Statement, information on how to provide feedback, and the importance of receiving feedback for the Community Access Road.

11.11 Record of Consultation and Engagement

The Record of Consultation and Engagement is a key component of the Final Environmental Assessment / Impact Statement, supporting fulfillment of federal and provincial requirements and commitments set out in the Marten Falls-Ontario Memorandum of Understanding on Shared Consultation Responsibilities. The Record of Consultation and Engagement is required by the Ontario *Environmental Assessment Act* and prepared in accordance with the Ministry of the Environment, Conservation and Parks Code of Practice.

The Record of Consultation and Engagement documents how input from Indigenous communities, government agencies, and interested persons was sought, received, and considered throughout the Assessment Process. It demonstrates the Project Team's commitment to meaningful consultation and engagement, transparent decision-making, and regulatory compliance.

11.11.1 Purpose and Reporting Period

The purpose of the Record of Consultation and Engagement is to: provide a transparent record of all communication, consultation, and engagement activities; categorize feedback received; and describe how input has informed the Assessment Process.

The reporting timeframe started with release of the Notice of Commencement of Environmental Assessment on October 29, 2021, and ended on September 5, 2025. Consultation and engagement activities for Milestones 1, 2, 3, and 4 are included:

- Milestone 1: Notice of Commencement of Environmental Assessment;
- Milestone 2: Effects Assessment Methods;
- Milestone 3: Identification of Preferred Alternatives; and
- Milestone 4: Review of the Draft Environmental Assessment / Impact Statement.

Consultation and engagement on Milestone 5: Review of Final Environmental Assessment / Impact Statement will be undertaken by the federal and provincial government agencies, with support from the Proponent up to the regulators' decision.

Formal comments submitted on the Draft Environmental Assessment / Impact Statement and responses to those comments are available in the Feedback and Response Log, **Appendix C** of the Final Environmental Assessment / Impact Statement.

11.11.2 Structure of the Record of Consultation and Engagement

The Record of Consultation and Engagement is comprised of multiple reports prepared at key milestones of the Assessment Process and separated by each audience group (Indigenous communities, government agencies, and interested persons).

While **Section 11** of the Final Environmental Assessment / Impact Statement is not a Record of Consultation and Engagement, it provides introductory content and a high-level summary of all consultation and engagement undertaken with Indigenous communities, government agencies, and interested persons.

Indigenous Communities: The Record of Consultation and Engagement for Indigenous Communities is comprised of four Milestone Progress Reports, each corresponding to a specific milestone of the Assessment Process:

- Milestone 1: Notice of Commencement of Provincial Environmental Assessment (October 29, 2021, to June 30, 2022);
- Milestone 2: Effects Assessment Methods (July 1, 2022, to May 31, 2023);
- Milestone 3: Identification of Preferred Alternatives (June 1, 2023, to July 31, 2024); and
- Milestone 4: Draft Environmental Assessment / Impact Statement (August 1, 2024, to September 5, 2025).

These reports were released as community-specific documents for each individual Indigenous community to review and comment before being release publicly.

Government Agencies: Consultation and engagement with government agencies is documented in a single Record of Consultation and Engagement covering the full reporting period from October 29, 2021, to September 5, 2025.

Interested Persons: Consultation and engagement with interested persons is documented in a single Record of Consultation and Engagement covering the full reporting period from October 29, 2021, to September 5, 2025.

All Final Environmental Assessment / Impact Statement Records of Consultation and Engagement are provided in **Appendix X**. Note a Draft Record of Consultation and Engagement for Interested Persons was released as part of the Draft Environmental Assessment / Impact Statement for review and comment.

The following sections are included in the interested persons and Indigenous community Records of Consultation and Engagement:

- **Summary of Key Consultation and Engagement Activities Undertaken During Preparation of the Environmental Assessment / Impact Statement** - an overview of key consultation and engagement activities, including when and where they happened, the number of participants, including any subgroups represented (if available), and a description of the associated information materials provided;
- **Summary of Feedback Received and Response / Action** - identifies specific issues raised, the corresponding topic, communication channel, response / action to the issue, and how it was addressed or considered in the Environmental Assessment / Impact Statement (if applicable);
- **Consultation and Engagement Log** - a detailed correspondence tracking table including date the correspondence occurred, method of consultation and engagement (for example, email, phone call, letter, in-person meeting), whether it was incoming or outgoing, contact name and title (if applicable), Project Team member involved (for example, Marten Falls First Nation Senior Community Member Advisor, Marten Falls First Nation Project Team, or Marten Falls First Nation Project Consultant), and a summary of the correspondence; and
- **Appendices** - the appendices include notices, letters, meeting summaries / minutes, presentations and correspondence, as applicable for each Record of Consultation and Engagement. Comment and interest tables for interested persons and Indigenous communities are available in those respective reports.

The Record of Consultation and Engagement for Indigenous Communities also includes community-specific tables to demonstrate level of effort in email and phone outreach. The number of outgoing communications compared to incoming, and the meetings offered compared to those held, are included.

To show level of effort, the only logistical correspondence—like scheduling a meeting—included in the appendix is when a meeting was not scheduled or was postponed.

The Record of Consultation and Engagement for Government Agencies includes a summary of activities and information outlining the effort undertaken by the Project Team to consult and engage with municipal, federal, and provincial government agencies.

11.12 Issue Resolution

Issues have been considered and addressed / resolved (or partially resolved) where possible. Unaddressed issues are reflected in the Environmental Assessment / Impact Statement for the regulator's consideration including information on efforts made to address the issue even if attempts were unsuccessful. If issues are raised outside of the mandate of the Proponent, the Marten Falls-Ontario Memorandum of Understanding on Shared Consultation Responsibilities allows that these issues can be addressed by Ontario (Ministry of the Environment, Conservation and Parks and Ministry of Mines).

12. Our Changing Climate

Climate change presents many challenges for infrastructure projects, particularly in remote areas like Marten Falls. This section explores how climate change could affect the Community Access Road and outlines a series of strategies to make it safer and more resilient. Climate events such as increased rainfall, flooding, wildfire risks, extreme heat, and ecosystem shifts (for example, changes in vegetation patterns, loss of critical wildlife habitats, or shifts in species distributions) have the potential to affect both the construction and long-term use of the Community Access Road. If climate events result in the closure of the Community Access Road, they will also affect Marten Falls First Nation and potentially other communities that rely on it.

As the climate continues to change, it is important to consider strategies for making the Community Access Road resilient so that it remains operational. This section outlines proposed adaptations to protect the Community Access Road and its users, including enhancing drainage to manage flood risks, employing techniques to minimize wildfire impacts, and implementing safety measures for workers during heat waves. Building resilient infrastructure aims to promote the Community Access Road's long-term stability and the safety of the communities that rely on it.

12.1 Background and Approach to Addressing Climate Change Impacts

12.1.1 Greenhouse Gases and Climate Change

Greenhouse gases are gases that trap heat and regulate Earth's temperature. They allow sunlight to enter the atmosphere but prevent some of the heat generated by the sunlight from escaping back into space. This process is similar to how a greenhouse works, which is why they are called greenhouse gases. Greenhouse gases are essential for keeping the Earth warm; however, human activities have increased their concentration in the atmosphere, resulting in a changing climate.

Some common greenhouse gases include water vapour, carbon dioxide, methane, nitrous oxide, and ozone. Greenhouse gases can be both natural and human made. Natural greenhouse gases are produced by natural sources and processes, such as animals and humans breathing, decomposition of plants, and water evaporation. Greenhouse gases caused by human activities include the burning of fossil fuels (for example, when driving a car or heating a home) and methane emitted by livestock, such as cows, during digestion.

Climate change is a global issue that impacts every region, including Canada. Greenhouse gases trap heat in Earth's atmosphere, leading to changes in climate patterns that affect water, land, and people. These changes result in effects such as rising temperatures, changing rainfall patterns, and more frequent extreme weather events, all of which impact food security, health, biodiversity, and economic stability.

12.1.2 Understanding Climate and Weather

It is important to understand the difference between weather and climate, as these are often used interchangeably but have distinct meanings.

12.1.2.1 Weather

Weather refers to the atmospheric conditions experienced daily, such as temperature, precipitation, wind, and humidity. It changes from day to day and can even vary significantly within a single day.

12.1.2.2 Climate

Climate, on the other hand, refers to the average weather conditions over a much longer period, typically 30 years or more. Climate helps us understand broader trends and patterns, such as how much rain an area typically receives during certain months or how average temperatures vary from season to season.

When weather patterns change consistently over time, the climate changes, impacting both natural and human systems. For instance, warmer temperatures can lead to earlier snowmelt, affecting water availability in summer. Climate changes can also influence animal migration patterns, plant blooming times, and the timing of hunting and fishing activities—important for Indigenous communities that rely on natural cycles for cultural and economic practices.

12.1.2.3 Human Influence on Climate Change

The climate change experienced today is largely caused by human activity. For 5,000 years before Common Era, the global population has grown from approximately 5 million to over 8 billion by the end of 2024. This exponential growth has fuelled greater demand for energy, food, and resources. As the population has expanded, so has the use of fossil fuels such as gasoline, diesel, and coal, along with the conversion of forests into farmland, ranches, and urban areas.

These greenhouse gases are responsible for warming Earth's atmosphere and driving changes in global climate patterns. In Canada, these changes have led to more severe wildfires, reduced ice cover on lakes and rivers, and altered agricultural productivity. For example, near the Community Access Road, Marten Falls First Nation members reported that the Albany River water levels were so low during the summer of 2024 that they could cross it on foot. Marten Falls First Nation members also reported changes in animal species while trapping and noted changes to animal behaviour, which affected the timing of the annual moose hunt in 2024. Such shifts highlight the importance of assessing climate risks for any new project, such as the Community Access Road, and make sure that infrastructure is designed to withstand future conditions.

12.1.3 Addressing Climate Change Impacts

There are two main ways to address climate change impacts: mitigation and adaptation.

12.1.3.1 Mitigation

Mitigation involves reducing greenhouse gas emissions to lessen the severity of climate change (Intergovernmental Panel on Climate Change, 2021). This includes reducing the use of fossil fuels, transitioning to renewable energy, and improving energy efficiency across various sectors. The Community Access Road incorporates mitigation measures to minimize emissions from construction and maintenance activities, as discussed in **Section 9.5.4.2.2**. These measures include maintaining construction and maintenance equipment.

12.1.3.2 Adaptation

Adaptation involves preparing for and managing current expected and anticipated climate impacts. For the Community Access Road, this means designing infrastructure to withstand expected and anticipated climate change conditions, such as increased rainfall, higher temperatures, frequent freeze-thaw cycles, and heightened flooding risks. The goal is to construct a road that is resilient and minimizes risks to surrounding communities in a changing climate.

12.1.4 Leveraging an Indigenous Climate Lens

Including different perspectives, particularly those of Indigenous communities who live near the Community Access Road and have a deep connection to the land, is important for understanding climate change and its potential impacts. In 2019, the Project Team initiated a program to gather Indigenous Knowledge. Indigenous Knowledge is based on generations of observations and interactions with the environment. This knowledge is

deeply rooted in the culture and traditions of Indigenous communities and provides unique insights into environmental changes that may not be captured by conventional scientific data.

Marten Falls First Nation engaged with 22 Indigenous communities throughout the environmental assessment process. Six of these communities provided feedback on the climate change study or in other formats, including:

- Fort Albany First Nation;
- Kashechewan First Nation;
- Kitchenuhmaykoosib Inninuwug;
- Marten Falls First Nation;
- Wapekeka First Nation; and
- Weenusk First Nation.

These communities contributed their knowledge through climate change webinars, workshops, supplemental documents, and surveys. Knowledge Keepers from these communities shared observations of environmental changes, such as shifts in animal migration patterns, changes in fish populations, and variations in vegetation health. For instance, they reported that certain bird species, including waterfowl, are migrating earlier in the spring and leaving later in the fall. These shifts have direct impacts on hunting practices, which are vital for food security and cultural heritage.

Additionally, community members have noted changes in fish populations, particularly a decline in cold-water species. Warmer water temperatures, changes in stream flows, and habitat degradation are believed to be contributing to these declines. The loss of key fish species has implications for food security, as fish are an important source of nutrition for many Indigenous communities. Changes in vegetation have also been reported, with some native plant species becoming less common, while other, more heat-tolerant species are increasingly prevalent.

Indigenous Knowledge has also highlighted the broader effects of climate change and anticipated extreme weather events on community life. Warmer winters and shorter winter access road seasons have disrupted traditional travel routes, making it more difficult for community members to access hunting and fishing areas. During the 2023 / 2024 winter season, most winter access roads to northern communities, including Marten Falls, were not opened or only opened for light traffic (Stimpson, 2024). As such, northern Ontario First Nations declared a state of emergency over winter roads (Global News, 2024). These changes impact not only the physical environment but also the cultural and social aspects of community life, as traditional activities are central to cultural identity and community well-being.

By combining Indigenous Knowledge with scientific research, a more comprehensive understanding of climate impacts can be achieved, enabling the development of sustainable and culturally respectful solutions.

12.2 Observed and Predicted Changes

Research on climate change and the Indigenous Knowledge considered during this study indicate that the Community Access Road area will become warmer and wetter in the future. By the end of the century (2071 to 2100), average temperatures are expected to increase by approximately 6.2 degrees Celsius (Intergovernmental Panel on Climate Change, 2021). This will likely result in longer heatwaves, changes in plant life, and shifts in ecosystems.

The number of days with temperatures above 30 degrees Celsius is expected to rise from an average of 1.4 days per year to approximately 6 days. This increase in heat poses health risks, weakens construction materials, and reduces agricultural productivity. More heatwaves may cause heat stress for community members and workers, while also making infrastructure maintenance more difficult. Warmer temperatures during the winter will lead to an increase in freeze-thaw cycles. The number of mid-season days with temperatures above 0 degrees Celsius will increase from on average 14 days to 27 days per season.

Annual precipitation is expected to increase by approximately 17 percent, with more rain and slightly less snow. This increase could result in more frequent flooding, increased soil erosion, and extra stress on drainage systems. These changes may affect the Community Access Road by causing erosion and damaging bridges and culverts. Shifts in rainfall patterns will likely result in more extreme rainfall events and longer dry periods. Such dry periods in combination with higher temperatures will likely lead to more wildfires. The Community Access Road could, to an extent, act as a limiting factor and a potential fire break.

Climate change will also impact ecosystem services, which are natural processes that provide benefits such as clean water, fertile soil, and healthy fish populations (Intergovernmental Panel on Climate Change, 2021). With the Community Access Road, challenges related to shorter ice seasons will be reduced, making access to hunting and trapping areas more reliable. However, changes in rainfall and temperature may still affect soil stability, water availability, and overall ecosystem health. Warmer weather can lead to an increase in invasive pests that damage trees and other plants, harming forest health and biodiversity. Other climate-tracking species, including birds, fish, insects, mammals, trees, bushes and grasses, may potentially change the composition of the ecosystem.

Seasonal shifts may result in drier conditions at certain times of the year, impacting the availability and quality of water. Reduced water supply and quality can threaten food security by reducing the number of fish and other aquatic resources. Changes in plant growth patterns may also impact the availability of medicinal plants that are important for traditional health practices, further disrupting cultural activities.

These changes disrupt not only the ecological balance but also the cultural, social, and economic life of local communities. Furthermore, climate change will shift the start date of construction for the winter road to later dates. At the same time, the spring melt will result in earlier closures of the winter road. Additionally, mid-winter melting events are projected to reduce the internal stability and potential closure of the winter road.

Refer to the Climate Adaptation and Resiliency Technical Support Document (Appendix Y) for more detail.

12.3 Adapting the Project for Future Climate Conditions

To prepare the Community Access Road for challenges caused by future climate, a climate change risk assessment was conducted using the Public Infrastructure Engineering Vulnerability Committee High-Level Screening Guide (Public Infrastructure Engineering Vulnerability Committee Global Partnership, 2021). This guide provides a systematic approach to evaluating climate risks and planning appropriate adaptation strategies. Full details of the climate change risk assessment are included in the Climate Adaptation and Resiliency Technical Support Document (Appendix Y) and summarized in the following sections.

12.3.1 Climate Change Risk Assessment

The Public Infrastructure Engineering Vulnerability Committee High-Level Screening Guide is a qualitative risk assessment process designed to help organizations understand potential future climate impacts on a project during construction, operations, and potentially decommissioning. The climate change risk assessment utilizes the following four steps:

- **Scope:** The assets being constructed by the project, the time horizons, and the emission scenarios for the climate change risk assessment were determined. For this climate change risk assessment, two future time horizons (2041 to 2070 and 2071 to 2100) were considered to the historical time horizon (1981 to 2010) under the worst-case emission scenario of continued and unabated emissions of

greenhouse gases. The 2041 to 2070 time horizon includes construction and near-future operations, and the 2071 to 2100 time horizon captures far-future operations and potential decommissioning. The worst-case scenario, without international efforts to reduce emissions, constitutes a conservative approach that may overestimate the risk. The assessment considered the Community Access Road, any supporting ancillary infrastructure, and the people who will construct, operate, and maintain the road, along with its users.

- **Data:** The next step involved collecting data to support the assessment, associated with both the Community Access Road and climate. The Community Access Road was broken into components and sub-components (also referred to as elements) of a similar nature for consideration in the climate change risk assessment. The climate records included historical weather records, future climate projections, and insights from Indigenous Knowledge (for example, observed changes to fish populations). Climate data was sourced from Environment Canada's climate reports and assessments by the Intergovernmental Panel on Climate Change (Intergovernmental Panel on Climate Change, 2021). To determine the climate-related risks to the Community Access Road, climate indicators and their relative changes to the historical time horizon were analyzed to develop a likelihood from 1 to 5. The identification of components of the Community Access Road, selected project relevant climate indicators, and their associated likelihood were prepared for the next step of the climate change risk assessment.
- **Assessment:** To develop a risk score for the interaction between a climate indicator and a project component, an impact consequence rating table was developed. It considered the potential impact across five categories including health and safety, infrastructure integrity, operational impact, financial impact to Marten Falls First Nation, and financial impact to the road owner. Each of these categories had five increasing levels of impact to allow for a potential consequence score of 1 to 5. A risk score was developed for each possible interaction between climate indicators and project components by multiplying the climate likelihood and the selected consequence score. Some interactions were not scored as the project component is not exposed to a particular climate indicator. For example, rest stops are not exposed to extreme temperatures. Resulting risk scores, from 1 to 25, were then classified as low risk (risk score less than or equal to 9), moderate risk (risk score between 10 and 16) and high risk (risk score greater than or equal to 20). Those interactions that resulted in a risk score classified as moderate or high risk were moved to the reporting step to develop adaptation measures to reduce the risk score.

- **Reporting:** The final step involved developing adaptation measures for interactions classified as moderate or high risk. These measures are presented in detail in the Climate Adaptation and Resiliency Technical Support Document (Appendix Y), with a summary provided in **Table 12-1**.

Table 12-1: Summary of Adaptation Measures

Climate Indicator	Adaptation Measures	Project Phase
Extreme Temperature and Heat Wave	Implement an alert protocol designed to identify and communicate hot weather and heat wave conditions that could impact the well-being of community members, visitors, and workers.	Construction/ Operations
	Enforce breaks for workers during construction, provide protective equipment and air conditioning in camps, and implement flexible work schedules during heat waves.	Construction
	Communicate the health risks of extreme heat events to the public, as recommended by Health Canada (2011). For example, share heat wave warnings and health safety tips on display signs in construction camps and community buildings.	Construction/ Operations
	Provide designated cool, shaded, or air-conditioned areas for workers to limit their exposure to extreme temperatures and heat.	Construction
Extreme Rainfall	Design drainage systems to handle heavy rainfall, with well-defined overland flow routes.	Construction
	Choose oversized culverts to account for the increase in the recurrence of floods and extreme rainfall of about 172 millimetres (in other words, the 100-year rainfall in 2071 to 2100).	Construction
	Conduct frequent grading and maintenance of the road to fill potholes and maintain a smooth surface that can handle heavy rainfall more effectively.	Operations
	Communicate the condition of the road to the public to encourage people to be careful when traveling. For example, share the location and status of floods or road washouts in construction camps and in community buildings. Include the road in the internet feed for road conditions reporting.	Construction/ Operations
Wildfire	Conduct regular maintenance and inspection of the road to prevent the accumulation of flammable debris and improve safe travel.	Operations
	Implement early warning systems to prepare for wildfire events and make informed decisions about road closures.	Operations
	Develop and implement an emergency preparedness and management plan in the case of a wildfire event.	Operations
Thunderstorm	Establish a storm warning system that alerts road users in advance so that they can plan their travel.	Operations
	Establish guidelines on what to do in case of a thunderstorm and communicate to road users.	Operations

12.3.2 Future Climate

While developing the associated climate data and future climate projections in the vicinity of the Community Access Road to support the climate change risk assessment, two areas of additional research were completed and included in the Climate Adaptation and Resiliency Technical Support Document (Appendix Y). The first is presented in **Attachment C**: Climate Change Impacts on Ecosystems, which includes insights from Indigenous Knowledge. The second is presented in **Attachment D**: Future Usability of the Winter Road.

12.4 Conclusion

After implementing the identified adaptation measures, the negative effects of the climate change on the Community Access Road could be reduced. However, it is important to recognize that while these strategies greatly enhance the Community Access Road's resilience, they do not eliminate all risks.

13. Other Regulatory Requirements

13.1 Accidents and Malfunctions

One of the federal requirements that needs to be met is an assessment of potential accidents and malfunctions of the Community Access Road. This can include the failure of certain works or incidents involving road users caused by technological malfunctions, human error or extreme weather events (for example, flooding, earthquake, forest fire).

As described previously in the Environmental Assessment / Impact Statement, the main phases of the Community Access Road include planning, detail design, construction and operations. Good planning can help prevent and / or minimize the potential for accidents and malfunctions. In addition to this, construction-specific and operations-specific safety measures and plans will be developed to help reduce the potential of accidents and malfunctions and support damage control if and when one occurs.

This section provides information on:

- Potential accidents and malfunctions (construction and operations);
- Plans to reduce their likelihood of occurring and response plans if one were to happen (construction and operations);
- Feedback from Indigenous communities and the public relating to potential accidents and malfunctions associated with the Community Access Road; and
- Cultural awareness and sensitivity.

13.1.1 Potential Accidents and Malfunctions

Based on the Community Access Road design and intended use, professional judgement and experience with other remote road projects, potential accidents or malfunctions are listed in **Table 13-1**. These were considered for the construction and operations phases. The construction phase is anticipated to take between 3 to 10 years, while the operations phase is expected to be permanent. The construction and operations phases of the Community Access Road are distinct in terms of management and responsibilities, often involving different entities.

The hazard identification and risk assessment for the Community Access Road is covered in **Section 12.3**.

Table 13-1: Potential Accidents or Malfunctions

Potential Accident or Malfunction	Phase	General Description
Spill	Construction	• Accidental spill of hazardous material (for example, fuel, dust suppressant, explosives) during storage, handling, or dispensing, resulting in the release of hazardous material on soils, vegetation or near a waterbody. • Exposure to toxic substances: workers or first responders may be exposed to toxic fumes or substances during an accident involving hazardous waste. • Vehicle accident or mechanical malfunction involving construction equipment or trucks, resulting in the release of hazardous materials such as hydraulic fluid, fuel, or oil on soils, vegetation or near a waterbody.
Spill	Operations	• Transportation of hazardous material (for example, fuel) accidental spill. • Vehicle accident or mechanical malfunction, resulting in the release of hazardous materials such as hydraulic fluid, fuel, or oil on soils, vegetation or near a waterbody.
Explosion or Fire	Construction / Operations	• A fire or explosion within project infrastructure, resulting in the release of contaminants to the atmospheric, aquatic, or terrestrial environment • A fire or explosion within project infrastructure causing injury to people or the environment.
Transportation, Storage and Use of Explosives	Construction / Operations	• Accidental discharge of bulk explosive supplies (ammonium nitrate) during transportation or storage, resulting in the release of contaminants to the aquatic or terrestrial environment • Accidental detonation of explosives causing injury to people.
Transportation Accidents	Construction	• Traffic accident (vehicle collision or rollover) during transport of project supplies and workers from camp accommodations to construction sites causing injury to people.
Transportation Accidents	Operations	• Traffic accident (vehicle collision) involving Community Access Road users causing injury to people. • Traffic accident (vehicle-pedestrian collision).
Extreme Weather Event Resulting in Infrastructure Failure	Construction / Operations	• Extreme weather event (rainfall, snowfall) resulting in the failure of infrastructure (culvert washout, bridges damage) and creating unsafe conditions for people and the environment.
Wildlife Encounter	Construction / Operations	• Physical Injuries: workers can suffer bites, scratches, or stings from animals such as snakes, spiders, or bees. These injuries can lead to pain, swelling, infections, or allergic reactions. • Property Damage: wildlife can cause damage to construction sites. Animals like rodents may chew through electrical wires or insulation, leading to potential hazards and additional repair costs. • Zoonotic Diseases: certain wildlife species can transmit diseases to humans. For example, bats and raccoons can carry rabies, while ticks can transmit Lyme disease. • Traffic accident (vehicle-wildlife collision).

13.1.2 Plans

13.1.2.1 Construction

Given the length and complexity to construct the Community Access Road, it is expected that more than one construction company (the contractor) will be involved. Accidents can be prevented through good planning and design. Safety measures will also have to be implemented to support reducing the likelihood of an accident happening and controlling one efficiently if one were to occur. One of the requirements that the owner / operator selected for the Community Access Road will have to fulfill is the preparation and implementation of the plans related to accidents and malfunctions. The prime owner / operator will be responsible for drafting plans, while contractors will be responsible for reviewing and implementing these plans.

A list of potential plans is provided below for consideration. The final list will be confirmed once the ownership of the Community Access Road is determined.

- **Spill Contingency Plan:** its objective is to protect the public, the environment and workers by having a quick and effective action plan to minimize harm. It will outline the steps to be taken if hazardous materials (for example, fuel and engine oil) are spilled during construction. It usually includes what to do on: immediate response, notification, cleanup and prevention, as well as information on equipment;
- **Waste Management Plan:** its objective is to help protect the environment by promoting recycling and proper disposal, as well as keeping workers safe by managing hazardous waste appropriately. It will include details on how construction waste will be handled, strategies on waste separation (for example, recyclables and hazardous waste), collection and storage, disposal, recycling, and minimization / reduction;
- **Emergency Response Plan:** its objective is for everyone to know what to do in an emergency, with an emphasis placed on protecting lives and minimizing damage. It will outline the actions to be taken during various emergencies or accidents. It can include risk assessment, identification of potential hazards specific to the construction site, response procedures, communication protocols, and evacuation plans. The construction of the Community Access Road is anticipated to take between 3 and 10 years. It is possible that during that period extreme climate-related events could occur. As such the Emergency Response Plans, which the owner / operator prepares, will also include provisions on dealing with extreme weather events such as wildfires, flooding and winter

storms. The addition of these will not only consider the safety of construction staff and the public, but also the protection of the Community Access Road, impacts to the surrounding environment, and consider preventing additional accidents (for example, spills or explosions);

- **Explosives Management Plan:** explosives will be used at aggregate sites. Therefore, an Explosives Management Plan will be prepared. Its objective is to protect workers, the public, and members of Indigenous communities by having explosives be used safely and responsibly. It will include storage protocols and handling procedures. It will also include emergency procedures, which list steps to take in case of an accidental detonation or other emergencies involving explosives;
- **Wildlife Management Plan:** its objective is to protect both wildlife and workers by minimizing harmful interactions. It can include monitoring, such as regularly checking for wildlife activity near the construction site, deterrent measures to keep animals away from the construction area, and response procedures if wildlife is encountered, including safe relocation methods; and
- **Traffic Management Plan:** its objective is to keep construction workers safe by managing traffic effectively. It can include traffic control measures (for example, signage and barriers), detours, and road closures and communication.

13.1.2.2 Operations

As with construction, the severity and frequency of accidents can be managed during operations through good planning and appropriate maintenance. Planning incorporates local knowledge and participation in the design and maintenance for such things as:

- Anticipating wildlife movements to limit interactions with vehicles;
- Weather forecasting to caution travellers or to close the road during adverse weather events;
- Routine maintenance activities such as:
  - Grading and addition of new aggregate;
  - Pothole repairs;
  - Flood management (for example, ditching, culvert repairs, and vegetation management); and
  - Snow removal;
- Emergency response capacity and capability.

Maintenance operations involve additional considerations, such as:

- Having appropriate capital assets available and maintained, such as trucks, plows, graders, emergency response vehicles / equipment, and associated supplies; and
- Well-trained labour to perform maintenance operations, ideally labour resident in Marten Falls (note, this is a business development opportunity as well as an employment opportunity).

The Community Access Road will be designed in accordance with the Ontario Ministry of Transportation's Roadside Design Manual (Ontario Ministry of Transportation, 2023). In addition to following the Roadside Design Manual, the geometric design criteria used for the design and construction of the Community Access Road will be based on the latest and best practices from the Transportation Association of Canada and Ministry of Transportation of Ontario Design Supplement. The engineers are also considering including pull outs / rest areas at regular intervals.

The Community Access Road will require consideration of the following safety and traffic management protocols:

- **Emergency Response Plan:** it will outline procedures for responding to various emergencies, such as spills, wildfires, and vehicle accidents. Given the remote location of the Community Access Road, it will have to consider the viability of installing and maintaining SOS phones to allow for people to get in contact with emergency services. The Emergency Response Plan could also include coordination with local / regional emergency services, environmental agencies, and wildlife management authorities;
- **Incident Management Plan:** it will detail the steps to be taken in the event of incidents like culvert blowouts or wildlife collisions;
- **Traffic Management Plan:** it is assumed that the average annual daily traffic to Marten Falls will be 100 vehicles. As such it is not expected that neighbouring communities will see a change in traffic as a result. However, if the Community Access Road is in the future connected to the Northern Road Link, it is estimated that traffic could then increase to an average annual daily traffic of 700 vehicles along the north-south section. It is expected that the same entity will operate and maintain both roads and that a traffic plan will be prepared as part of their operations. Given the traffic-related concerns raised by Indigenous communities, it is recommended that the owner / operator work with Indigenous communities on the preparation of a traffic plan. It could include information on traffic control measures (for example, potential construction of a bypass, signage, and barriers), detours, road closures, and communication; and

- **Communication Protocols:** effective communication is essential during emergencies. These protocols aligns relevant parties, including emergency services, maintenance crews, the public, and Indigenous communities so that they are informed and coordinated during incidents. Given the remote location of the Community Access Road, the communications protocol will also have to consider how to allow users to report issues (for example, potholes, dead animals on the road, and car accidents) as well as how the operator can notify users of potential hazards ahead (for example, road maintenance, icy driving conditions, and road closures).

13.1.3 Engagement and Feedback

Marten Falls First Nation has been consulting and engaging with 22 Indigenous communities as well as the public and have received feedback on many topics. Indigenous communities and the public have also provided feedback to the Agency, and this is available on the Agency's registry. **Table 13-2** presents the feedback obtained on traffic, community safety, and impacts to humans, traditional subsistence, and cultural resources. It lists feedback directly sent to Marten Falls First Nation. At the time of writing this Environmental Assessment / Impact Statement, no feedback relating to accidents or malfunctions was listed on the Agency's registry. The following quotes are from Marten Falls First Nation community members.

> The first time building a road was mentioned one elder said to build it on hard ground, "not in the muskeg as it will be difficult to maintain it."
> — **Rosie Achneepineskum**

> We will need to monitor the all-season road for safety, security and maintenance purposes. Tracking vehicles by having a registration system at each access point would help people to know if a vehicle has arrived at their destination. Forest fire alert systems should be in place. A system for vehicles that break down or are involved in accidents. Random checks for illegal substances may also be necessary. — **Sandra Moonias**

> Monitoring wildlife and natural issues of concern (for example, flooding, fallen trees, snowdrifts and plans) for dealing with these issues need to be made. A mechanic should be accessible when necessary. Road maintenance crews should be available. The need to remove a dead moose or bear struck by a vehicle will be necessary at times and a plan should be made for this. In the past, Marten Falls First Nation community members used the trail radio system to communicate. This could be used or satellite phones for emergencies. Passing lanes and turning around areas for vehicles in case of a wildfire, flooding, etc. — **Sandra Moonias**

Table 13-2: Summary of Engagement Feedback Received by Marten Falls First Nation

Comment	Source	Response
Representatives noted that the community is already dealing with a lot of mining traffic and there was a fear that this Project could make said traffic worse.	Animbiigoo-Zaagi'igan Anishinaabek First Nation	Roadside safety is of paramount importance. The Community Access Road will be designed in accordance with the Ministry of Transportation Ontario's Roadside Design Manual. In addition to the manual, the geometric design criteria used for the design and construction of the Community Access Road will be based on the latest best practices from the Transportation Association of Canada and Ministry of Transportation Ontario's Design Supplement. The designers are also looking at including elements from the Ministry of Transportation Ontario's 2+1 Roadway Site Selection and Design Parameters report, which may include truck passing lanes and pull outs / turnouts along the route (Ministry of Transportation Ontario, 2021).
Communication highlighted several concerns they believed the Community Access Road may have on community safety. In summary, these concerns were related to road safety as there will be the potential for more vehicle collisions due to increased vehicles on the roads and personal safety, especially as it relates to women and girls, as well as to two-spirit, lesbian, gay, bisexual, transgender, queer, intersex, and additional people who identify as part of sexual and gender-diverse communities citizens.	Métis Nation of Ontario	Potential impacts will be evaluated, as required, and mitigation and monitoring programs will be proposed through the Environmental Assessment / Impact Statement (Community Well-Being Technical Support Document; **Appendix T**).
A member raised safety concerns related to future truck activity on the Community Access Road including dust, noise, low visibility, and speeding.	Marten Falls First Nation	Provisions for dust suppression on account of truck traffic are being included and therefore the width is 11 metres. Dust suppressant products are being examined that are acceptable to both the environment and have been proven to work. Noise controls may be exercised in populated areas (for example, braking).
Concerns expressed about road safety (rest areas along the way equipped for survival).	Aroland First Nation	Concerns were noted and will be considered during detail design.
Concern that the Project could cause an increase in traffic and more non-Indigenous harvesters into the area impacting traditional resources.	Kashechewan First Nation	Concerns were noted and incorporated into the Kashechewan Aboriginal and / or Treaty Rights and Interests: Assessment Report. The following mitigation measures is noted in Appendix U when referring to the future owner/operator: The Proponent will discuss possible restrictions for hunting in the Project Area with the Ministry of Natural Resources.

13.1.4 Cultural Awareness and Sensitivity

As discussed in **Section 1**, colonialization, government policies, residential schools, and the incursion of newcomers, among many other factors, have had a devastating impact on the Anishinaabeg. The Indigenous communities in the area are working towards strengthening their communities and culture, salvaging their teachings and knowledge, and improving their lives.

Generally, accidents and malfunctions relate to technical aspects of a project (**Table 13-1**). However, the lack of an appropriate plan to support Indigenous communities and non-Indigenous workers in their interactions could also be considered as a potential accident and malfunction to the Anishinaabeg culture. Some examples include:

- **Disruption of Sacred Sites:** respecting and recognizing sacred Indigenous sites in construction projects helps preserve these important areas, fostering cultural and spiritual well-being for Indigenous communities and promoting harmonious progress without conflicts or delays;
- **Environmental Damage:** incorporating traditional ecological knowledge into design and maintenance plans can limit adverse disruption to ecosystems valued by the Indigenous community. This protects access to valued Indigenous activities such as hunting, trapping, and medicine gathering; and
- **Cultural Misunderstandings:** proactive Cultural Awareness training for workers can avoid misunderstandings and conflicts. For example, workers with cultural awareness training will more likely respect local customs and sensitivities.

During construction the owner / operator will be required to provide mandatory, ongoing cultural awareness and sensitivity training to protect the Anishinaabeg, with guidance and support from Marten Falls First Nation. The training should be developed with the communities so that opening roads to the north does not result in further damage but can be used to build trust and understanding and protect the Anishinaabeg culture among others. The ongoing aspect of the training and exposure to the Anishinaabeg culture will better support non-Indigenous workers deepen their understanding.

13.1.4.1 Potential Mitigation Measures

During construction the owner / operator will be encouraged to consider the following cultural sensitivity / awareness plans and prepare / implement them as applicable:

- **Community Engagement and Consultation:** this should include early and ongoing engagement with Indigenous communities including the establishment of feedback mechanisms. This should also include checking on culturally appropriate communication methods and traditional protocols;

- **Cultural Competency Training:** this could include training programs, workshops and seminars. This could include training for all project staff on Indigenous cultures, histories, and contemporary issues to deepen understanding and sensitivity;
- **Cultural Protocols and Practices:** this could consider integrating cultural practices and ceremonies into project milestones where appropriate (for example, a ground-breaking ceremony or Pow Wow). It could also consider working with communities to identify opportunities for workers to attend cultural events;
- **Health and Safety Considerations:** this could include the development of safety protocols that consider cultural practices and community needs;
- **Monitoring and Reporting:** to confirm the plan is working adequately, regular monitoring by a qualified individual should be completed for compliance with cultural sensitivity commitments. In addition to this, making reports on progress and any issues accessible to Indigenous communities will foster transparency and help strengthen relationships;
- **Local Road Board:** could be established, using the Ontario *Local Roads Board Act* as a framework with representatives of Marten Falls First Nation as part of it (Government of Ontario, 1990e). It could include responsibility for the construction and operations of the Community Access Road, as well as for levying taxes to fund these activities and enter into agreements with other road-related project entities;
- **Anti-human Trafficking Plan:** should include training for employees and Marten Falls First Nation members to recognize and report signs of trafficking. Additionally, the plan could consider establishing a reporting mechanism for suspected trafficking incidents and provide support for victims. The plan should be developed with the collaboration of Marten Falls First Nation and local law enforcement to monitor and address trafficking risks. The plan should also be regularly reviewed so that it remains effective and that it is updated as needed;
- **Culturally Appropriate Reporting System:** consider establishing an easy-to-use and culturally sensitive reporting system. This system should be developed in collaboration with Indigenous communities to confirm it respects traditional protocols and communication methods;
- **Community Support and Engagement:** work with communities to identify ways in which to support community members overcome apprehension about reporting, making them feel comfortable and heard. This could include regular community meetings and feedback sessions to build trust and transparency;

- **Incident Response Team:** it is important for the incident response team to be well-trained in cultural sensitivity. This team should include representatives from Indigenous communities so that responses are appropriate and respectful;
- **Immediate and Long-term Support:** offer immediate support to those affected by incidents, such as counseling services and community support programs. Additionally, consider developing long-term support plans to address ongoing impacts of incidents;
- **Investigation Process:** reported incidents should be investigated thoroughly and transparently, and in a timely manner. Findings should be shared with the affected communities and involve them in the resolution process;
- **Continuous Improvement:** the response plan should be reviewed regularly. Feedback from Indigenous communities and lessons learned from past incidents should be used to update it, as appropriate;
- **Training and Awareness:** ongoing training on how to handle cultural sensitivity incidents; and
- **Documentation and Reporting:** detailed records of incidents and the actions taken in response should be well documented. Regularly report on these incidents to Indigenous communities to maintain transparency and accountability is highly recommended.

13.2 Meeting Canada's Environmental Obligations and Climate Change Commitments

The Tailored Impact Statement Guidelines (Impact Assessment Agency of Canada. 2020) require information on how the Community Access Road may contribute to Canada's ability to meet its environmental obligations and commitments.

- Currently many goods, including fuel, are transported to Marten Falls via the winter access road for a few weeks of the year and via air during the other remaining months. The Community Access Road will allow for easy access year-round.

> Road access will benefit people with cost of living, transportation for people to come in and out. Perhaps create more jobs for people in the long run. Would like to see solar system in place for certain things, for example greenhouses grow our own vegetables, heat. — **Norma Achneepineskum**

- Measures contemplated in the construction and design of the Community Access Road to limit its climate change impacts include the following:
  - There are sections of the road that will be on peatlands. Leaving these in place to avoid releasing carbon stored in the peatlands will be considered;
  - Requiring that equipment used during construction and operations are well maintained; and
  - Providing transportation to construction workers between construction camps and sites.
- The Tailored Impact Statement Guidelines identify federal environmental obligations that may be relevant to the Community Access Road. How these obligations were considered is described below:
  - The Ungulates Technical Support Document notes that caribou are listed as Threatened on Schedule 1 of the *Species at Risk Act* (**Appendix M**) (Government of Canada, 2024b). Mitigation measures were identified and described to lessen potential adverse effects, including maintaining consistency with any applicable recovery strategy, action plan, or management plan;
  - Eight Species at Risk were identified with the potential to occur within the wildlife Local Study Areas (Wildlife Technical Support Document; **Appendix K**). The Wildlife Technical Support Document describes mitigation measures that align with federal provincial recovery, management, or action plans and strategies. Required timing windows to avoid tree removals during sensitive timing windows will be respected during construction;
  - One fish Species of Conservation Concern, Lake Sturgeon, was identified as having potential to occur within the fish and fish habitat Local and Regional Study Areas (Fish and Fish Habitat Technical Support Document; **Appendix G**). Where feasible, areas of sensitive fish habitat and restricted activity timing windows will be avoided;
  - Sixteen bird Species at Risk were identified with potential to occur within in the birds Local and Regional Study Areas (Birds Technical Support Document; **Appendix L**). The *Migratory Bird Convention Act* nesting season (April 28 to August 14) will be considered, so construction clearing activities will occur between August 15 and April 27, where possible (Government of Canada, 2017c). If vegetation clearing is required during the migratory bird nesting season, non-intrusive pre-clearing nest surveys will occur within 7 days prior to clearing; and

  - One plant Species at Risk, Pitcher's Thistle (gaachiichiyaag waabigwanii), has the potential to occur within the vegetation Local Study Area (Vegetation Technical Support Document; **Appendix J**). Habitat description provided in the Recovery Strategy for Pitcher's Thistle (Cirsium pitcheri) in Canada (Parks Canada Agency, 2011) to characterize the suitability of all ecosites mapped within the vegetation Local Study Area was used (Vegetation Technical Support Document).

- Ontario's approach to have ecosystem representation within its network of protected areas uses the Landform / Vegetation Association as a surrogate for biodiversity. A Preliminary Biodiversity Offset Plan has been developed and is included in **Appendix AB** of the Final Environmental Assessment / Impact Statement. The specific approach will be determined through consultation with Environment and Climate Change Canada; Ontario Ministry of the Conservation, Environment and Parks; and Ontario Ministry of Natural Resources.

13.3 Contributions to Sustainability

Another requirement under the Tailored Impact Statement Guidelines is the inclusion of a project's contributions to sustainability. The Assessment Process is a tool to check the sustainability of projects. The three principles of sustainability are environmental sustainability, social sustainability, and economic sustainability. As part of the analysis, potential mitigation measures are used to attempt to balance environmental impacts against development / social gains. During the route selection process, the Community Access Road prioritized environmental sustainability by analyzing data collected in the water and land categories. This analysis confirmed that the Preferred Route for each of the three segments were those that had the least impact on the environment compared to other options. Environmental sustainability was a key consideration throughout, influencing not only the Preferred Route selection but also the development of mitigation measures and monitoring activities.

The main purpose for the Community Access Road is to provide opportunities to future generations of Marten Falls First Nation and to make the Community sustainable. The Community Access Road will support social and economic sustainability for Marten Falls First Nation. As mentioned in **Section 2**, the Community Access Road will make travel safer and lower the cost of food, fuel, and other supplies. It will also improve community services like health, education and wellness, and open up new opportunities for the Community to grow. The Community Access Road will make a positive contribution to Marten Falls First Nation' social interaction, as the community members will be able to travel in and out of the Community to visit relatives living inside and

outside of Marten Falls. In addition to these benefits, the Community Access Road can also be used by others like other Indigenous communities, mining, forestry, and tourism. The Community Access Road can create jobs during construction, maintenance, and operations. It will improve the Community's access to employment opportunities because people would be able to reliably commute to work year-round.

Beyond these benefits, the Community Access Road is more than an infrastructure development; it is a lifeline for the Marten Falls First Nation community, supporting its long-term sustainability and resiliency. Rooted in the principles of mino-bimaadiziwin (living a good life) and the Seven Grandfathers teachings, the Project emphasizes respect for all of Creation and the importance of living a balanced and healthy life. By integrating these teachings, the Project fosters a connection between infrastructure development and cultural values, so that future generations can thrive in harmony with the environment.

By improving access to essential services such as healthcare, education, and employment, the Project addresses critical socio-community challenges. It enhances public safety, particularly for children and Elders, while preserving traditional practices and access to traditional food sources. The Project also aims to reduce strain on public finances and improve housing options, fostering a healthier and more sustainable community. By promoting local work force participation and providing training opportunities, the Community Access Road seeks to empower the Community, creating lasting positive impacts. These benefits contribute to the Community's ability to thrive and adapt to future challenges.

The Project will contribute to sustainability by:

- Requiring the owner / operator to consider sustainable materials (in other words, materials that are recycled, recyclable, or sustainably sourced), and implement energy efficient construction practices and technologies, where practicable;
- Requiring the owner / operator to minimize construction waste, which includes recycling materials and reducing the amount of waste sent to landfills, and reduce water consumption by implementing rainwater harvest and greywater recycling systems, where practicable; and
- Integrating Indigenous teachings, such as mino-bimaadiziwin (living a good life) and the Seven Grandfathers teachings, to guide sustainable decision-making and promote a balanced and respectful relationship with the environment.

14. Monitoring Programs and Future Commitments

The Environmental Assessment / Impact Statement must include information on monitoring programs and future commitments to comply with both federal and provincial requirements.

Monitoring programs are important because they allow regulators, Indigenous communities and specialists to verify that the mitigations and predicted results described in the effects assessment are working as expected. They can also be used to identify potential changes or new and unexpected consequences of those mitigations. This is important as it allows the road operators to make adjustments to mitigation approaches, so they remain effective and that enhancement measures work as intended. Where the approaches are not working it allows for the opportunity to develop updated mitigations or enhancement measures.

Monitoring programs also include future commitments related to mitigating residual effects. A Project-specific environmental monitoring program will be developed during detail design and will include the monitoring commitments related to the various valued components.

Section 9 of each Technical Support Document in Appendix F to Appendix V include detailed information on monitoring programs to be conducted during pre-construction, construction and operations; as well as future commitments. **Appendix AA** includes a compilation of monitoring programs, and mitigation and enhancement measures.

14.1 Pre-Construction Monitoring Programs

Pre-construction is also referred to as detail design, and within these sections, these terms are used interchangeably. During detail design the route and temporary and permanent associated infrastructure will be further refined, and environmental permits and approvals will be obtained for both construction and operations of the Community Access Road. More information on the details noted in the sections below can be found in the respective discipline's Technical Support Document in the appendices of the Environmental Assessment / Impact Statement.

14.1.1 Water

14.1.1.1 Surface Water

Prior to construction, the following monitoring programs will be required:

- Surface water surveys using methods for ground-based surveys (during high and low stream flow conditions, where possible) at any waterbody crossing location that has not already been assessed as part of the field investigations and at water crossings where work is proposed below the high-water mark to meet additional permitting requirements; and
- If new waterbodies are identified, an Aquatics Specialist will be required to assess the new waterbody. Depending on the nature of the waterbody, recommendations for construction methods, appropriate mitigation measures, and permitting requirements will be made by the Aquatics Specialist and, when necessary, local First Nation communities and appropriate regulatory agencies including Fisheries and Oceans Canada and Ministry of Natural Resources will be engaged. This will allow for the appropriate mitigation measures to be implemented during construction at each waterbody crossing at a site-specific level, which will reduce or avoid potential effects on surface water quantity, surface water quality and sediment quality.

During detail design, site-specific surface water surveys will be complete to support engineering and permitting at waterbody crossings where work below high-water mark is proposed. Submit designs of waterbody crossings as required for permit applications to Fisheries and Oceans Canada and Ministry of Natural Resources.

14.1.1.2 Fish and Fish Habitat

Prior to construction, the following monitoring programs will be required:

- Fish and fish habitat and surface water surveys methods will be conducted before construction at any waterbody that has not been assessed and work is proposed below the high-water mark to meet permitting requirements (in other words, for the Fisheries and Oceans Canada Request for Review under the *Fisheries Act* and for permit applications to the Ministry of Natural Resources under the *Lakes and Rivers Improvement Act*); and
- If new waterbodies are identified prior to construction, an Aquatics Specialist will assess the waterbody. Depending on the nature of the waterbody, recommendations for construction methods, appropriate mitigation and

enhancement measures, and permitting requirements will be made by the Aquatics Specialist and, when necessary, local First Nation communities and appropriate regulatory agencies including Fisheries and Oceans Canada and the Ministry of Natural Resources, will be engaged. This will allow for the appropriate mitigation and enhancement measures to be implemented during construction at each waterbody crossing at a site-specific level, which will reduce or avoid potential effects on habitat quantity and quality.

14.1.1.3 Groundwater and Geochemistry

Prior to construction, the following monitoring programs are recommended. Specific details of the monitoring will be confirmed by and directed by a qualified person retained for environmental monitoring of the Project.

A groundwater monitoring program to establish baseline groundwater levels and quality. Groundwater levels and quality will be monitored as follows:

- Groundwater monitoring stations will be established at areas where large groundwater takings are expected or where potential for impacts on groundwater quality exists, such as pits, quarries, temporary construction camps, laydown yards, road constructed over peatland, and large structure foundations or road cuts / fills;
- The groundwater monitoring stations will be located between the anticipated work area and nearby receptors such as wetlands, waterbodies, and seeps / springs. Multiple groundwater monitoring stations may be required at larger sites to assess effects on various or large receptors and the groundwater monitors should provide depth coverage to at least the expected water taking depth;
- Groundwater levels will be measured at the monitoring stations at least monthly for 3 months prior to beginning groundwater taking. For pits and quarries which will be extracted below the water table under an Ontario *Aggregate Resources Act* permit, the groundwater monitoring program will be designed in accordance with the Aggregate Resources of Ontario: Technical Reports and Information Standards (Government of Ontario, 2023c) in addition to the Project monitoring program;
- Groundwater quality will be sampled at the monitoring stations at least monthly for 3 months prior to beginning construction work. The groundwater quality samples should be analyzed for general water quality parameters at minimum (such as., pH, temperature, conductivity, hardness, alkalinity, chloride, nitrate, nitrite, sulphate, phosphate, ammonia, total dissolved solids, dissolved organic

carbon, calcium, copper, iron, magnesium, manganese, potassium, sodium, and zinc). Sampling for metal parameters will include both dissolved and total concentrations to assess the influence of suspended solids on the concentrations. Additional parameters of concern should also be sampled for where identified, for example sampling for volatile organic compounds near areas where fuel or chemical storage is located; and

- In addition to the above recommended pre-construction monitoring, at sites where construction activities will require permitting for dewatering and water management such as Permit to Take Water, Environmental Activity and Sector Registry, and / or Environmental Compliance Approvals, the groundwater monitoring will be enhanced on a site-by-site basis to support the required permitting studies.

A geochemical testing and monitoring program to assess the potential for acid rock drainage from any soils, or bedrock, which will be exposed during construction. As part of this monitoring program:

- Acid base accounting analysis will be carried out and materials assessed for acid rock drainage potential based on the classification as outlined in Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (Price, 2009).

Marten Falls First Nation has also noted interest in highlighting the importance of combining western science hydrology and Indigenous Knowledge (Marten Falls First Nation, 2023e). The Community noted that relevant Indigenous Knowledge provided by Marten Falls First Nation may be integrated into the groundwater monitoring program to provide a holistic approach to the Project's monitoring activities. To further this goal, Indigenous Environmental Monitors will be included in the monitoring program.

14.1.1.4 Peatlands

During detail design, the following tasks will be undertaken to minimize effects on peatland ecosystems:

- Refine peatland community mapping and field-verify the locations of sensitive or difficult to restore communities (such as fens and bogs) to inform the micro-siting of temporary access roads, staging areas, camps, debris and / or timber stockpiles, as well as the centreline of the Community Access Road within the 100 metre cleared right-of-way;

- Complete an assessment of pit / quarry locations to identify potential effects due to changes in hydrogeology / hydrology on peatland communities within the radius of influence for dewatering programs;
- Airborne Electromagnetic Surveying to produce continuous peat depth mapping. which is critical for construction planning such as identifying saturated or sensitive areas that may require specialized engineering solutions.

In addition, the following pre-construction monitoring programs and additional studies will be developed and initiated:

- A peatlands groundwater monitoring and water budget study will be developed and implemented during detail design to determine groundwater flow and influence on peatland ecosystems. This will further inform the assessment of the potential Project impacts on peatland ecosystems and the associated mitigation recommendations that will be confirmed and refined at detail design.
- A program designed to monitor groundwater on both sides of the Community Access Road and in areas of dewatering programs to establish pre-construction groundwater levels, as well as monitor groundwater levels during construction and post-construction. This program will include pre-construction, construction, and post-construction components. This also includes the creation of a monitoring program to include further geochemical testing on exposed bedrock and soils and determine the potential for acid rock drainage and / or metal leaching as it relates to methylmercury production in peatland communities present within the Construction Disturbance Area. The program will also monitor potential increases in methylmercury production related to changes in groundwater levels as a result of the construction of the Community Access Road. At a minimum, the program will include the following activities. Monitoring requirements will be further developed during detail design.
- Locations of groundwater monitoring instruments (such as piezometers) will be established approximately every 1,000 metres along sections of the road that will be constructed with the “floating road” construction methodology. Details of the monitoring plan including the final placement of piezometers and the duration of monitoring will be developed and refined during detail design.
- Monitoring locations will be established both up- and down-gradient of the future road to capture pre-construction, construction, and post-construction groundwater levels and movement patterns. Monitoring locations should be located away from equalization culverts.
- Monitoring will occur three times annually (spring, summer, fall).

- In addition to the pre-construction surface water monitoring programs specified in the Surface Water Technical Support Document (**Appendix F**), a pre-construction peatlands hydrological monitoring and water budget study will be developed and implemented. This will further inform the assessment of potential Project impacts on peatlands and the associated recommended mitigation measures (such as the culvert size and locations) that will be confirmed at detail design.

During detail design, the following activities will be completed:

- Complete an assessment of pit / quarry locations to identify potential effects due to changes in hydrogeology / hydrology on peatland communities within the radius of influence for dewatering programs.
- Prepare a Vegetation Restoration Plan that includes measures specific to peatland communities and peatland restoration, including peat stockpile management. This plan will be developed through engagement and consultation with Indigenous communities and integration of local Indigenous Knowledge and stewardship protocols.
- Implement a program designed to monitor groundwater on both sides of the Community Access Road and in areas of dewatering programs to establish pre-construction groundwater levels, as well as monitor groundwater levels during and post-construction.
- Develop a pre-construction peatlands hydrological monitoring and water budget study to further inform the assessment of potential Project impacts on peatlands and the associated recommended mitigation measures (such as culvert size and locations) that will be confirmed at detail design.

14.1.2 Land

14.1.2.1 Vegetation

During detail design, the following tasks will be undertaken to minimize effects on vegetation valued components:

- Refine vegetation community mapping and field-verify the locations of sensitive or difficult to restore vegetation communities (for example, organic wetlands) to inform the micro-siting of temporary access roads, staging areas, camps, debris and / or timber stockpiles, as well as the centreline of the Community Access Road within the 100-metre cleared right-of-way;

- Collaborate with the design team during the micro-siting of temporary access roads, staging areas, camps, and debris and / or timber stockpiles to minimize effects on known Traditional Use Plant harvesting areas, where possible;
- Reassess the status of Black Ash protection. If Schedule 1 of Ontario Regulation 6/24 has been updated to include the Construction Disturbance Area, a search for Black Ash trees will be completed at the Ogoki River crossing. Other suitable habitat in the south portion of the Construction Disturbance Area may also need to be searched. The scope of this additional assessment will be determined in consultation with regulatory agencies. If Black Ash trees are anticipated to be affected by the Project, regulatory agencies (Ministry of the Environment, Conservation and Parks, Environment and Climate Change Canada) will be consulted on next steps; and
- Complete an assessment of pit / quarry locations to identify potential effects due to changes in hydrogeology / hydrology on vegetation communities within the radius of influence for dewatering programs.

In addition, the following pre-construction monitoring programs and additional studies will be developed and initiated:

- A peatlands groundwater monitoring and water budget study will be developed and implemented during detail design to determine groundwater flow and influence on peatland ecosystems (a component of wetland ecosystems). This will further inform the assessment of the potential Project impacts on wetland ecosystems and the associated mitigation recommendations that will be confirmed and refined at detail design;
- Airborne Electromagnetic Surveying to produce continuous peat depth mapping which is critical for construction planning such as identifying saturated or sensitive areas that may require specialized engineering solutions;
- A program designed to monitor groundwater on both sides of the Community Access Road and in areas of dewatering programs to establish pre-construction groundwater levels, as well as monitor groundwater levels during construction and post-construction. This program will include pre-construction, construction, and post-construction components;
- Locations of groundwater monitoring instruments (for example, piezometers), will be also determined in consultation with vegetation ecologists and Indigenous communities so that effects on vegetation valued components are considered when determining their placement;

- Any programs as identified in the Peatlands Technical Support Document (**Appendix I**);
- In addition, a Vegetation Restoration Plan will be developed at detail design. This plan will include measures that are specific to peatland communities and peatland restoration, including peat stockpile management. This plan will be developed through engagement and consultation with Indigenous communities and integration of local Indigenous Knowledge and stewardship protocols; and
- Additional consultation with Ontario Parks will be completed at the detail design stage to determine permitting, mitigation and / or compensation or offsetting expectations for direct impacts to the Albany River Provincial Park and impacts to Critical Landform / Vegetation Associations.

14.1.2.2 Wildlife

Baseline data collected from existing conditions wildlife field program completed between 2019 to 2023, are expected to be adequate for pre-construction monitoring of all wildlife valued components except for beavers. Due to the importance of beavers to Indigenous communities and the uncertainty with respect to the effect of the Project on populations of furbearers and the fact that there are gaps in the existing conditions data, an additional aerial survey for active beaver lodges will be completed throughout the effects assessment Local Study Area to complement existing conditions data and refine the baseline characterization of beaver distribution. Pre-construction existing conditions for beaver can then be compared to post- construction conditions using the same survey approach.

Should the initiation of construction be delayed for an extended period of time (for example, five or more years), additional baseline monitoring may be required to update an assessment of adverse effects during the *Endangered Species Act* authorization process.

14.1.2.3 Birds

- Baseline data collected for breeding birds and marsh birds during point count and autonomous recording unit surveys from 2018 to 2022 are assumed to be adequate for pre-construction monitoring; and
- Additional pre-construction monitoring has been proposed, including the following program:
  - Pileated woodpecker habitat assessments, including an evaluation based on aerial interpretation and ground-truthed ahead of pre-clearing activities. These assessments are meant to keep project activities in compliance with the *Migratory*

Birds Convention Act (Government of Canada, 1994), specifically identified under the Migratory Birds Regulations in reference to pileated woodpecker. Pileated Woodpecker assessments will be completed in advance of the Project commencing construction, factoring in requirements for nest monitoring per Environment and Climate Change Canada guidance (for example, monitoring potential pileated woodpecker nest cavity trees for a period of 3 years).

14.1.2.4 Ungulates

Additional pre-construction monitoring for ungulates is not required. Baseline data collected from caribou collaring in 2021 to 2025, caribou and moose winter aerial surveys in 2022 to 2023, and remote camera monitoring surveys from 2021 to 2023, in addition to baseline data collected from caribou collared by Ministry of Natural Resources and for the Webequie Supply Road and Northern Road Link, are expected to be adequate to inform baseline conditions of ungulates.

Should the initiation of construction be delayed for an extended period of time (for example, five or more years), additional baseline monitoring may be required to update an assessment of adverse effects during the Endangered Species Act authorization process.

14.1.2.5 Physiography, Terrain, and Soils

During detail design, the following activities will be completed:

- The Soil Management Plan will be developed and followed for construction and operations;
- Develop and implement a geochemical testing and monitoring program to assess the potential for acid rock drainage from any soils, or bedrock, which will be exposed during aggregate extraction;
- Develop and implement a Spill Prevention and Emergency Response Plan;
- Develop and implement a Blasting and Communication Management Plan;
- Work with the Ministry of Transportation, and the Northern Road Link and Webequie Supply Road Project Teams to develop a coordinated approach to permafrost assessment; and
- Develop and follow recommendations outlined in a Permafrost Management Plan.

14.1.3 People

14.1.3.1 Aboriginal and / or Treaty Rights and Interests

The following Aboriginal and / or Treaty Rights and Interests-specific mitigation measures are proposed and must be confirmed with relevant parties, including Marten Falls First Nation and the province:

- Collaboration with local existing environmental advisory committees to support the development and implementation of all environmental monitoring programs. The objective is to include Indigenous interests and perspectives, particularly concerning resources utilized for rights-based purposes. In the absence of an existing advisory committee with an aligned mandate to Marten Falls First Nation, a Terms of Reference between relevant agencies and Indigenous communities will be established; and
- Collaborate with Indigenous communities to further weave Indigenous Knowledge into the current understanding of existing conditions. It is anticipated the Indigenous Knowledge could include wildlife observations, movement, migration routes, seasonal ranges, and fish health.

14.1.3.2 Acoustic and Vibration Environment

- Develop a Construction Vibration Workplan prior to the start of construction describing the construction schedule, list of construction equipment, list of point of reception locations (such as, traditional land use, residential, heritage structures and utilities), applicable guidance documents including criteria and control measures.

14.1.3.3 Cultural Heritage

- Research and evaluate the potential Mid-Albany Cultural Heritage Landscape and its associated potential heritage attributes for Cultural Heritage Value or Interest and level of significance. The research and evaluation should be completed by a qualified person(s) and recorded in a Cultural Heritage Evaluation Report;
- The Cultural Heritage Evaluation Report will use Ontario Regulation 9/06 or Ontario Regulation 10/06 of the *Ontario Heritage Act* to evaluate for Cultural Heritage Value or Interest of the potential cultural heritage landscape in accordance with the Ontario *Heritage Act* and the Ontario Standards and Guidelines for Conservation of Provincial Heritage Properties. Should any portions of the Local Study Area be found to have

provincial heritage significance under Ontario Regulation 10/06, additional work may require Minister's Consent, as defined in Section 3 of the Ontario *Heritage Act*; and

- If the potential cultural heritage landscape is determined to meet the criteria of either Ontario Regulation 9/06 or Ontario Regulation 10/06 of the Ontario *Heritage Act,* and continues to be adversely impacted by the Project, it is recommended that a Heritage Impact Assessment be prepared to fully assess impacts, including long-term residual effects, and propose mitigation measures to conserve the Cultural Heritage Value or Interest of the cultural heritage landscape.

14.1.3.4 Archaeology

- A Stage 2 Archaeological Assessment is required on the areas identified as having archaeological potential in the Stage 1 Archaeological Assessments;
- Any areas identified as having archaeological potential in the future Stage 2 Archaeological Assessment must complete a Stage 3 or Stage 4 Archaeological Assessment;
- Based on the findings of the partial Stage 2 Archaeological Assessment, a Stage 3 Archaeological Assessment is required at the Caviar (EiIp-1) site;
- The Stage 2 archaeological assessment must be conducted by a licensed archaeologist and must follow the requirements set out in Section 2.1.5 of the Standards and Guidelines for Consultant Archaeologists (Government of Ontario, 2011) for special survey conditions in northern Ontario and on Canadian Shield terrain;
- Test pit survey is required at 5 metre intervals in areas that fall within 50 metres of an identified modern water source. Survey is not required beyond 50 metres of this type of feature of archaeological potential;
- Where areas of archaeological potential include land adjacent to historic water sources (such as, glacial shorelines), or other areas identified as having archaeological potential based on the results of the Stage 1 archaeological assessment including the Aboriginal knowledge information, test pits will be placed at a maximum of 5 metre intervals between 0 and 50 metre from the feature, and at 10 metre intervals between 50 and 150 metre from the feature. Survey is not required beyond 150 metres of the archaeological features; and
- Poorly drained areas and areas of steep slope are to be mapped and photographed.

Archaeological investigations have the potential to reveal buried human remains. Should human remains be identified during any stage of work, the Proponent will be

informed immediately, and all archaeological work will halt until the proper authorities have been notified and permission to resume work has been granted, if required.

14.1.3.5 Atmospheric and Greenhouse Gas

Re-evaluation of potential significance or effect from temporary work camps is recommended following final design.

14.1.3.6 Community Well-Being

- The owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation to discuss community concerns and proposed topics, including those in relation to changes in population or social demographics;
- Owner / operator to develop and implement Diversity, Equity, and Inclusion hiring policies to prioritize women and reduce gender disparities;
- The owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation to discuss construction-related issues and unemployment by identifying and removing employment barriers, offering job readiness programs, and providing counseling and addiction support services to support community members;
- Owner / operator to develop and implement Community Readiness Strategies and Adaptive Management Plans to assess and respond to community needs;
- Develop a comprehensive inventory of the labour and business / procurement / contracting requirements for the project by identifying project requirements (in other words, labour needs, business / procurement needs and contracting needs); and categorizing requirements by time frame (in other words, short-term, medium-term, and long-term);
- Develop a comprehensive inventory of the Marten Fall First Nation and Aroland First Nation current labour and business / procurement / contracting capacities and capabilities to address the Project's requirements by engaging Marten Falls First Nation and Aroland First Nation leaders and members virtually; collecting data (in other words, labour market information; and business and procurement data); analyzing and categorizing skills inventory, business capabilities and contracting experience;
- Conduct a labour and business / procurement / contracting demand and supply gap analysis and develop initiatives to address the gaps;
- Create a Local Content Plan to utilize a certain dollar value or share of operations towards local businesses and owner / operators;

- Owner / operator to create a Local Training Plan to complete a local skills assessment and utilize local labour force;
- Owner / operator to provide information on available opportunities and training programs to help community members obtain necessary qualifications;
- Owner / operator to offer ongoing job readiness programs and coordinate training timing to support workforce transition and career growth;
- Owner / operator to develop and implement Diversity, Equity, and Inclusion hiring policy to prioritize women and reduce gender disparities;
- Owner / operator will develop an Equipment Mobilization Plan with both Marten Falls First Nation and Aroland First Nation for the movement of equipment, personnel, supplies, and resources. Where possible, construction traffic should be separated from community traffic to improve safety and minimize disruptions. The mobilization plan should also include a clear communications strategy to keep the community informed of the mobilization schedule, so that residents are aware of periods of increased heavy equipment traffic on the winter access road;
- Owner / operator will establish working groups with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including topics avoiding pressure on local, essential services and infrastructure;
- Owner / operator will develop waste management policies to minimize waste production and support responsible disposal. Collaboration with the community will be prioritized to develop effective construction waste management and disposal strategies, incorporating local input;
- Owner / operator will establish a secure fuel storage facility and maintain a reliable fuel supply throughout the construction season. Fuel deliveries will be planned in advance and transported via the winter access road, reducing reliance on costly air transport and preserving community fuel resources. All fuel storage sites will comply with safety and environmental regulations to prevent spills and contamination;
- Owner / operator to establish working groups with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the construction of the Community Access Road, including topics associated with housing adequacy, and converting construction camps to permanent housing;
- House workers in autonomous camps to limit demographic shifts and reduce pressure on community housing;

- Prior to construction, owner / operator will develop Access Management Plans with Marten Falls First Nation and Aroland First Nation in relation to hunting, trapping and gathering activities. All activities must conform to licensing requirements and adhere to the rules and regulations under the Ministry of Natural Resources;
- Compile information on use of surface water for transient recreational and potable water sources and locations of use;
- Conduct surface water sampling where project effects are likely to interact with use of surface water for transient recreational and potable water sources to establish existing conditions;
- Owner / operator to work with communities and governments, as required, to support education and development of Indigenous Conservation Officer (Game Warden) program;
- Supplement existing conditions information related to the chemicals or concern present in country foods with the collection of additional samples from Marten Falls First Nation and Aroland First Nation members over several years;
- Explore opportunities to increase total Driver Licence holders, alongside the Ministry of Transportation, including partnerships with third-party remote licence providers;
- Develop Equipment Mobilization Plans with local First Nations for the movement of equipment, personnel, and supplies;
- Develop, with the Ministry of Health, onsite safety and emergency preparedness programs to include fire suppression systems, medical care, security personnel, monitor safety compliance, emergency response plans and clear communication protocols between construction teams and emergency responders; and
- Chemical analysis of quarry materials to be used in road construction should be completed during detail design. These materials will ultimately make up the majority of the fugitive dust created during road construction and operations. Interpretation of this information can be used to source materials with the least potential impacts and to support appropriate mitigations are implemented.

Access to Clean Water - Water Quality:

- For groundwater, a pre-construction geochemical testing and monitoring program to assess the potential for acid rock drainage from any soils or bedrock that will be exposed during construction. The groundwater quality samples should be analyzed for general water quality parameters at minimum (such as, pH, temperature, conductivity, hardness, alkalinity, chloride, nitrate, nitrite, sulphate,

phosphate, ammonia, total dissolved solids, dissolved organic carbon, calcium, copper, iron, magnesium, manganese, potassium, sodium, and zinc). Additional parameters of concern should also be sampled for where identified.

Traditional Foods:

- During detail design, develop and implement a geochemical testing and monitoring program to assess the potential for acid rock drainage from any soils or bedrock that would be exposed during aggregate extraction. Include assessment of the material proposed to be used for road construction for potential for metal leaching and metal composition. Fugitive dust from the Project will be made up of materials proposed to be used for road construction.

14.1.3.7 Land and Resource Use

The owner of the road should be in negotiations with land users for the area that have expressed concerns with impacts associated with socio-economic losses as a result of the Community Access Road. Continued consultation during detail design will be required to address these concerns and comments. Future discussions and engagement with Ontario Parks will be completed during detail design to implement a communication strategy in order to provide ample notice for recreation users in the areas of construction.

14.1.3.8 Visual Environment

- Ground truth sensitive receptors and viewsheds within / adjacent to the Construction Disturbance Area;
- Identify design and construction constraints that protect visual character (buffers, edge form, finishes, lighting);
- Establish more robust existing conditions, photographic records, and dark-sky reference conditions at crossing locations and near Marten Falls;
- Point Receptor Validation and Protected or Priority No-Go View Cone Mapping: Field verification with Indigenous Knowledge holders, Parks representatives, or other applicable community representatives to confirm exact lines of sight for specific locations that hold unique, sacred, or otherwise special, Indigenous cultural or sense of place value points identified during this assessment or through further engagement. These are locations that would be considered absolute no-go locations for Project-related visual environment effects; wherein destruction of the overall visual character (for example, clearing of all vegetation and constructing a road) of

this precise location would be detrimental. One example of this type of location could be a burial ground. Further engagement and ground-truthing is required to identify these precise locations during the final design and micro-siting stages of the Project;

- Install, surveyed photo-stations (minimum three at each of the Albany River Crossing and Ogoki River Crossing): upstream near, upstream mid, downstream near; plus, two along the Marten Falls approach, and areas identified in the task and deliverable preceding (Point Receptor Validation and Protected or Priority No-Go View Cone Mapping). Capture leaf-on and leaf-off daytime sets; one night set under dark, clear conditions;
- Approve fixture cutsheets (for example, for temporary task lights), construction lighting plans with curfews, and mock-ups / samples for matte / low-reflectance finishes. For the finishes of major crossings, community feedback should be garnered to decide on things like paint colour, or if textures / designs could be incorporated into concrete components, with the overall goal of reducing the structures contrast;
- Pre-clearing stakeout of irregular edges and feathering blocks; micro-siting of abutments / approaches to minimize profile in where there are major sightlines where feasible;
- One field campaign per season prior to first clearing (at minimum, spring and late summer) and
- Led by the Environmental / Visual Lead with Indigenous monitors and Parks staff (for works inside park boundaries).
- Existing condition and follow-up photo-monitoring and ground-truthing for absolute no-go locations, and recommended at minimum for Albany and Ogoki River Crossings and Marten Falls approach (day and night), using fixed, surveyed photograph points;
- Co-development of finishes and edges with Indigenous Knowledge holders (including a workshop to share mock-ups, and site walks as necessary to understand the existing visual environment. The goal should be to get the communities feedback on what colours or architectural finishes could feasible be used to reduce the overall visual contrast of the major crossings);
- Lighting control: no continuous lighting; task-only, full cut-off fixtures with curfews; night audits;
- Staging of temporary construction areas within the view cone of absolute no-go or priority areas; and providing notice for when construction will occur and where;

- Feathered edges at major crossing locations, or where feasible; retain screening vegetation; naturalised shoreline shaping with local materials;
- Targeted screening at validated headlight lines of sight (low berms / dense planting) or other protected or priority locations if needed;
- Progressive reclamation of temporary surfaces with organics salvage and native seeding if required; and
- Coordination with Northern Road Link and Anaconda and Painter Lake Upgrades on lighting, staging, and sequencing at shared nodes to reduce cumulative duration and clutter where there is spatial and temporal overlap between the Projects.

14.2 Construction Monitoring Programs

Construction is the time when physical work to the road and associated facilities is being completed onsite, including things like clearing, grubbing or any early works site clearing activities. During this period, the road and all facilities are constructed, and teams may continue to obtain permits for operations. More information on the details noted in the sections below can be found in the respective disciplines Technical Support Document in the appendices of the Environmental Assessment / Impact Statement.

14.2.1 Water

14.2.1.1 Surface Water

During construction, the following monitoring programs will be required for surface water in the Local Study Area:

- In-situ monitoring of one or more surface water quantity and quality parameters (including but not limited to water taking and discharge rates, pH, temperature, dissolved oxygen, turbidity, conductivity, and other contaminants of concerns as required) and sampling for laboratory analysis of surface water quality parameters (including but not limited to hardness, alkalinity, total suspended solids, total dissolved solids, dissolved organic carbon, biochemical oxygen demand, major and minor ions (including sulphate), total metals, nutrients (total phosphorus, total ammonia, total Kjeldahl nitrogen), total and dissolved organic carbon, and other contaminants of concerns as required) will be conducted at water taking and / or discharge locations to satisfy the conditions / requirements of Water Taking and Discharge Plans related to applicable permits and approvals (for example, Permit to Take Water, Environmental Compliance Approval and / or Environmental Activity and Sector Registry), and to confirm the effectiveness of

the Water Taking and Discharge Plans and associated mitigation and enhancement measures. Qualified environmental personnel (with expertise in surface water and water quality such as a water resources engineer) will be retained for monitoring program to help confirm that the proposed environmental safeguards are in place, and effectively utilized in protecting the environment;

- Monitoring / inspecting all erosion and sediment management measures, bank stabilization features, and cofferdams during construction to verify the performance and effectiveness of mitigation and enhancement measures; and
- Monitoring of total suspended solids and / or turbidity (instrumented measurements and / or visual observations), as well as visual inspections to confirm the presence or absence of oil or sheen, will be coupled with monitoring of streamflow rates and / or water levels, as required to meet regulatory or permitting requirements, at all water crossings targeted for in-stream works during construction to verify effectiveness of construction procedures and mitigation measures including dam and pump / diversion activities associated with the removal and / or installation of temporary or permanent crossing structures. An Adaptive Management Plan will be developed in the event of an unexpected change to water quantity or quality (in other words, increase in turbidity in accordance with Canadian Council of Ministers of the Environment standards). Adaptive Management Plan will be provided in permit / approval application for review by regulatory authorities in advance of any construction activities, as applicable.

14.2.1.2 Fish and Fish Habitat

During construction, the following monitoring programs will be required:

- Environmental Monitors and Indigenous Environmental Monitors will be onsite during construction to confirm that all waterbodies crossed by the Community Access Road right-of-way and access roads have been identified and documented in the waterbody crossing list. The Environmental Monitors will monitor the installation, use, and removal of waterbody crossing structures. The Environmental Monitors will confirm that the appropriate waterbody crossing structure is being used and that the required Fisheries and Oceans Canada and the Ministry of Natural Resources approvals and permits are in place;
- If new waterbodies are identified during construction, the waterbody will be clearly flagged and activity will be suspended within 30 metres of the location until an Aquatic Specialist has assessed the waterbody and determined a

suitable course of action, which may include contacting Fisheries and Oceans Canada and the Ministry of Natural Resources;

- Appropriate erosion and sedimentation control measures will be installed, monitored, and managed to minimize or avoid sediment mobilization from the disturbed area to drainages or waterbodies. Adequate and appropriate erosion and sedimentation control materials will be onsite and available prior to commencement of construction;
- A Licence to Collect Fish for Scientific Purposes from the Ministry of Natural Resources will be obtained and Aquatics Specialists will rescue and relocate fish within the isolated workspace prior to construction in the isolated workspace; and
- Turbidity and total suspended solids will be monitored according to Fisheries and Oceans Canada, and the Ministry of Natural Resources permit requirements and will follow the Canadian Council of Ministers of the Environment's Canadian Water Quality Guidelines for the Protection of Aquatic Life (Canadian Council of Ministers of the Environment, 1999).

14.2.1.3 Groundwater and Geochemistry

A groundwater monitoring program to measure groundwater levels and quality and compare them to existing conditions. Groundwater levels and quality will be monitored as follows:

- Groundwater monitoring stations established for the pre-construction monitoring programs will be maintained and monitored through construction;
- Groundwater levels will be measured at the monitoring stations at least weekly during construction activities. During active groundwater takings, the nearby groundwater levels will be measured at least daily;
- Groundwater quality will be sampled at the monitoring stations at least monthly for the same parameters as the pre-construction monitoring; and
- In addition to the above recommended construction monitoring, at sites where construction activities require permits for dewatering and water management such as Permit to Take Water, Environmental Activity and Sector Registry, and / or Environmental Compliance Approvals, the groundwater monitoring will be enhanced and maintained on a site-by-site basis to support any permit requirements.

As construction proceeds, the monitoring program may need to be modified or updated based on changing conditions or work plans. The monitoring program will be overseen

by and directed by a qualified person retained for environmental monitoring of the Project and will include Indigenous Environmental Monitors.

14.2.1.4 Peatlands

During construction, the following monitoring programs will be required. These programs will be further developed during the preparation of the Environmental Protection Plan in consultation with Indigenous communities:

- An invasive species monitoring program designed to prevent, detect, and control (in other words remove) invasive species and monitor areas where invasive species were removed;
- A program designed to monitor groundwater on both sides of the Community Access Road to determine whether water flow beneath the road is being maintained throughout construction will be carried out where the “floating road” construction methodology is used through peatland communities. Monitoring will occur at the same locations established during pre-construction and will occur three times annually (spring, summer, fall) throughout the duration of construction;
- A program to monitor peatland community response to any potential changes in hydrogeology throughout construction (such as in the vicinity of dewatering activities and either side of “floating road” segments);
- A program to monitor for peatland condition in the vicinity of Project activities. The program will include science-based thresholds or indicators of peatland condition based on research and established standards, as well as mitigation and adaptive response plan to prevent long-term damage or carbon release;
- In addition to the construction surface water monitoring programs specified in the Surface Water Technical Support Document (**Appendix F**), monitoring of peatland hydrology will also be conducted. The requirements of this monitoring program will be determined at detail design, and
- A program to monitor whether erosion and sedimentation control measures are functioning as intended and to direct repair and adaptive management measures, where required.

14.2.2 Land

14.2.2.1 Vegetation

During construction, the following monitoring programs will be required. These programs will be further developed during the preparation of the Environmental Protection Plan in consultation with Indigenous communities:

- An invasive species monitoring program designed to prevent, detect, and control (in other words, remove) invasive species and monitor areas where invasive species were removed;
- A program designed to monitor any rare plant, or Species at Risk protection measures that have been implemented (for example, check for damage or failure of protection fencing and make repairs);
- A program designed to monitor groundwater on both sides of the Community Access Road to determine whether water flow beneath the road is being maintained throughout construction will be carried out where the “floating road” construction method is used through peatland communities. Additional details are provided in the Peatlands Technical Support Document (**Appendix I**);
- A program to monitor vegetation community response to any potential changes in hydrology or hydrogeology throughout construction (for example, in the vicinity of dewatering activities and either side of “floating road” segments); and
- A program to monitor whether erosion and sedimentation control measures are functioning as intended and to direct repair and adaptive management measures, where required.

14.2.2.2 Wildlife

Engagement and consultation with Indigenous communities and federal and provincial regulators, as well as requirements outlined in federal and provincial permits, will determine the monitoring programs during construction.

During construction, the following monitoring programs may be required:

- An Environmental Monitor and Indigenous Environmental Monitor will be retained to monitor the development footprint during construction to identify and sensitive wildlife features that have not previously been identified on or near the Construction Disturbance Area. In the event that a sensitive feature is identified

(or suspected to be present) it will be afforded protection according to the Environmental Protection Plan;

- A reporting protocol and system to report incidental wildlife observations and wildlife-vehicle collisions (bats, furbearers and other large mammals, and reptiles and amphibians) during construction and operations will be developed. The details of the incidental wildlife and wildlife-vehicle collision reporting system will be described in the Environmental Protection Plan;
- Waste management and site surveillance monitoring would be completed to avoid attraction of wildlife to the Project and associated risks of adverse human-wildlife interactions. Potential problem areas at the Project would be identified as part of monitoring, which could lead to the implementation of targeted mitigation measures in these areas to limit human-wildlife conflicts. The details of the waste management and site surveillance monitoring will be described in the Waste Management Plan and Environmental Protection Plan;
- Ground-based or aerial pre-clearing surveys (“wildlife sweeps”) will be completed within a biologically relevant distance of the Construction Disturbance Area under the direction of the Environmental Monitor and Indigenous Environmental Monitor, prior to any clearing or grubbing. The wildlife sweeps will entail surveying for sensitive wildlife features, including mammal dens, beaver lodges, amphibian and reptile habitats, and bat maternity roost habitat, and documenting the presence of large mammals;
- Details of the ground-based pre-clearing surveys (wildlife sweeps) will be described in the Environmental Protection Plan, which will be prepared prior to the Project authorization process so as to inform federal and provincial authorizations, as necessary;
- The wildlife sweeps will include surveys to identify potential Species at Risk bat maternity roost habitat within the Construction Disturbance Area to determine the presence of potential bat habitat prior to any tree clearing to be conducted during the bat maternity roost season (May 1 to September 30). Surveys would be conducted to search the Construction Disturbance Area for trees that could provided roosts for little brown myotis and northern myotis (candidate roost trees). Candidate roost trees are defined as trees greater than 10 centimetres diameter at 1.3 metres above the ground, with exfoliating bark, cracks, crevices, or cavities;
- If potential maternity roosting habitat is identified and planned to be removed during the roosting period, bat exit surveys may be conducted depending on the

outcome of consultation and *Endangered Species Act* (Government of Ontario, 2007) permitting with the Ministry of the Environment, Conservation and Parks Species at Risk Branch;

- Construction activities causing loud noises including the use of heavy machinery will not be undertaken adjacent to (in other words, within 50 metres) candidate or confirmed maternity roosts between half an hour before sunset to half an hour after sunrise during the maternity roost season;
- The wildlife sweeps will include surveys to identify American marten dens (and the dens of other furbearing mammals) within the Construction Disturbance Area to determine mammal presence prior to any clearing or grubbing / excavation. Any American marten dens observed will be marked as sensitive and be afforded protection prior to any construction. In the event that American marten dens are identified the mitigation described in the Wildlife Technical Support Document will be followed (**Appendix K**). In the event that dens of other furbearing mammals are observed, mitigation measures outlined in the Environmental Protection Plan will be followed;
- The wildlife sweeps will include surveys to identify beaver lodges within the Construction Disturbance Area to determine potential beaver habitat prior to any clearing or grubbing / excavation or installation of bridges or culverts. Any beaver lodges observed will be marked as sensitive and be afforded protection prior to any construction. In the event that beaver lodges are identified the mitigation described in the Wildlife Technical Support Document will be followed (**Appendix K**);
- The wildlife sweeps will include surveys for reptiles and amphibian. Any reptiles or amphibians found within work areas will be relocated to suitable habitat nearby. Safe handling practices will be used to move turtles, snakes and other herpetofauna to areas away from the construction (for example, Ontario Species at Risk Handling Manual: For Endangered Species Act Authorization Holders; Ministry of Natural Resources, 2014c);
- Areas with potential to support wolverine denning will be identified through a review of plant community mapping (looking for communities that may contain the microhabitat features), and targeted aerial site reconnaissance during the same denning period that construction activities are planned to survey for signs of potential denning areas prior to the initiation of construction activities (for example, clearing and grubbing);

- If clearing or grubbing are required during the wolverine denning period (January 15 to May 31) in habitat suitable for wolverine denning, surveys for the presence of wolverine dens will be conducted prior to clearing. Surveys will be conducted from helicopters or drones. The survey extent will include all potentially suitable denning habitat within 4 kilometres of the disturbance. Den sites require a physical structure such as fallen trees, earthen banks, woody debris, or boulders with snow cover for additional structure and insulation (Scrafford and Ray, 2022). All treed communities (including swamps, forests, treed fens, and treed bogs), all eskers and other prominent terrain features, all rock barrens, all thicket swamps, all watercourse and lakeshore riparian area, and all forestry cut blocks have potential to support maternal denning, Open water and open wetlands such as marshes, open fens, and open fens are not considered suitable for maternal denning;
- The methods of the surveys will be determined in consultation with the Ministry of the Environment, Conservation and Parks Species at Risk Branch and will be described in the Environmental Protection Plan;
- Due to the difficulty in confirming the presence of a wolverine den through aerial surveys, a conservative approach will be taken to the identification of potential wolverine dens and denning areas. The positive identification of potential wolverine denning site or denning areas will use a weight of evidence approach and consider several observations including:
  - Several wolverine tracks observed in the search area;
  - Wolverine tracks concentrated in certain areas; and
  - Wolverine tracks observed disappearing into snow covered blowdown or drifts.
- Observations of wildlife and wildlife signs will be documented and reported to the owner / operator's Environmental Monitor and the Environmental Monitor will confirm all Species at Risk observations are reported to the Natural Heritage Information Centre as per the Report Rare Species (Animals and Plants) site (Ministry of Natural Resources, 2014) and to Ministry of the Environment, Conservation, and Parks – Species at Risk Branch at SAROntario@ontario.ca.

14.2.2.3 Birds

During construction, the following monitoring programs will be required:

- Clearing activities will occur outside the breeding season for most bird species, from August 15 to April 27, where possible (90 percent of species in nesting zones C5 and C6 are expected to be actively nesting between April 28 and August 14; Environment and Climate Change Canada, 2023d);

- If any clearing is required during the migratory bird nesting season (April 28 through August 14), non-intrusive pre-clearing nest surveys will occur within 3 to 7 days prior to clearing; the maximum number of days prior to clearing will depend on the time during the nesting season:
  - During the peak migratory bird nesting season (when more than 40 percent of birds are predicted to be nesting; May 19 through July 30) non-intrusive pre-clearing nest surveys will be completed a maximum of 3 days prior to clearing;
  - During non-peak nesting periods (April 28 through May 18 and July 31 through August 14), non-intrusive pre-clearing nest surveys will be completed a maximum of 7 days prior to clearing; and
  - Pre-clearing nest surveys will be completed by avian biologists with support from Indigenous Environmental Monitors, where possible.
- If any areas are found to have birds exhibiting breeding behaviour during non-intrusive pre-clearing nest surveys, these areas, including an activity disturbance buffer, will be flagged, and protected from disturbance until the fledglings have left the nest or the nest is otherwise deemed unoccupied (in other words, the nest is depredated);
- In addition to nest surveys during the migratory bird nesting season, wildlife sweeps will be completed outside of the nesting season to look for and document pileated woodpecker nesting cavities and raptor stick nests. Wildlife sweeps will focus on mature and old growth forest dominated by deciduous trees as these habitats are most likely to have large trees that can support raptor stick nests and pileated woodpecker nests. Wildlife sweeps will be led by avian biologists with support from Indigenous Environmental Monitors, where possible; and
- The effectiveness of mitigation measures will be evaluated during construction and operations, and mitigation measures will be modified or enhanced as necessary through adaptive management.

14.2.2.4 Ungulates

Engagement and consultation with Indigenous communities and federal and provincial regulators during the permitting phase, as well as requirements outlined in federal and provincial permits, will determine the monitoring programs during construction.

A sensitive data license agreement will be established with the Ministry of the Environment, Conservation and Parks' Species at Risk Branch for the Project (in other

words, owner / operator) to acquire boreal caribou protected habitat information, which will support monitoring and other proposed mitigation commitments during construction.

An Ungulates Management and Monitoring Plan will be developed as part of the Environmental Protection Plan. Recommendations for mitigations and monitoring approaches provided by First Nations during the comment period of the Draft Environmental Assessment / Impact Statement will be considered for inclusion in the Ungulates Management and Monitoring Plan. During construction, the following monitoring programs may be required:

- Clearing, construction activities and decommissioning of temporary construction areas in and within 10 kilometres of Category 1 nursery use areas will occur outside the sensitive timing window of May 1 to September 15, to the extent practical. Clearing and construction activities in and within 10 kilometres of Category 1 winter use areas will occur outside the sensitive timing window of December 1 to March 31, to the extent practical. If activity restrictions cannot be followed for construction activities, Indigenous communities, in addition to the Ministry of Environment, Conservation and Parks, will be engaged to determine alternative approaches. This may include daily monitoring of caribou locations with collars and only commencing construction activities if collar data indicates that there are no caribou within pre-defined “cautionary zones” (pre-defined spatial buffer areas);
- Cautionary zones will be pre-defined spatial buffer areas based on the level of sensory disturbance expected for the activity;
- A hierarchy of mitigation actions based on disturbance type, distance from caribou, and season will be established;
- In addition to the intensive monitoring during sensitive seasons described above, ground-based or aerial pre-clearing surveys (“wildlife sweeps”) will be completed outside of the sensitive timing windows and within a biologically relevant distance of the Construction Disturbance Area under the direction of the Environmental Monitor, prior to any clearing or grubbing. The wildlife sweeps will entail surveying for sensitive wildlife features, including mammal dens, beaver lodges, amphibian and reptile habitats, and bat maternity roost habitat, and documenting the presence of large mammals. Trained staff will survey the area to be cleared or where blasting will take place by foot, all-terrain vehicle, snow machine or truck. An Indigenous Environmental Monitor will participate in pre-clearing surveys. Observations of wildlife and sign will be documented and reported to the owner / operator’s Environmental Manager and the Environmental Manager will help to confirm all Species at Risk observations will be reported to the Natural

Heritage Information Centre as per the Report Rare Species (Animals and Plants) site ((Ministry of Natural Resources, 2014) and to Ministry of the Environment, Conservation, and Parks – Species at Risk Branch at SAROntario@ontario.ca. Details of the ground-based pre-clearing surveys (wildlife sweeps) will be described in the Environmental Protection Plan which will be prepared prior to the Project authorization process so as to inform federal and provincial authorizations, as necessary;

- Indigenous Environmental Monitors will be on site during construction to confirm adherence to all mitigation and monitoring commitments for the Project [as summarized in Table 7-31 of the Ungulates Technical Support Document (**Appendix M**) and in any subsequent permits] and that the required approvals and permits are in place;
- The effectiveness of mitigation measures will be evaluated during construction, and mitigation measures will be modified or enhanced as necessary through adaptive management; and
- A reporting protocol and system will be developed to report Species at Risk observations, including resulting from collisions, during construction and operations, to the Ministry of Natural Resources Natural Heritage Information centre. The details of the incidental wildlife and wildlife-vehicle collision reporting system will be described in the Environmental Protection Plan.

During construction, operations, the following Before-After Control-Impact monitoring programs are potential approaches that could be discussed and evaluated as options during engagement and consultation:

- Deploying and maintaining Global Positioning System collars on adult female caribou, for comparison of caribou seasonal movement patterns, habitat use and mortality in the vicinity of the Project compared to historical Ministry of Natural Resources collar data and collar data collected during baseline studies (2021 to 2024). Monitoring the movements of female caribou in the vicinity of the Project will allow for identification of changes related to areas where caribou occur during sensitive / vulnerable periods as well as their seasonal movement patterns, including possible travel corridors, during construction and operations. Monitoring with collars also would include conducting mortality investigations of collared animals as they occur; this will provide information about changes in causes of mortality during Construction and operations. The number of collars and duration of years for monitoring during Construction and operations will be determined through engagement with Ministry of Environment, Conservation and Parks;

- Deploying and maintaining Global Positioning System collars on adult female moose, for comparison with seasonal movement patterns, habitat use and mortality data from moose collars deployed by Ministry of Natural Resources in the moose Wildlife Management Units pre-construction (anticipated deployment in 2025). Monitoring the movements of female moose in the vicinity of the Project will allow for identification of changes related to areas where moose occur during sensitive / vulnerable periods as well as their seasonal movement patterns during construction and operations. Monitoring with collars also would include conducting mortality investigations of collared animals as they occur; this will provide information about changes in causes of mortality during Construction and operations. The number of collars and duration of years for monitoring during Construction and operations will be determined through engagement with Ministry of Natural Resources;
- Remote camera monitoring at selected reference sites (in other words, locations surveyed in the alternative Project route Local Study Area during baseline surveys from 2021 to 2023 and on undisturbed sites) and within the vicinity of the Project. Remote camera monitoring will provide information about the occurrence and distribution of large mammals in the ungulate Local Study Area and whether there are changes in ungulate presence, habitat use and predation risk with the addition of the Project. Remote cameras could be deployed for a continuous period of at least 2 years during construction and at least 2 years during operations; the need for surveys further into operations will be determined through engagement with the Ministry of Environment, Conservation and Parks;
- More frequent aerial surveys for moose within the ungulate Local Study Area and the moose Wildlife Management Units in the moose Regional Study Area (01D, 17, 18A) in collaboration with the Ministry of Natural Resources. Aerial survey monitoring will provide information about moose population trends, occurrence and distribution in the ungulate Local Study Area and moose Regional Study Area and whether there are changes in moose population size and demographics with the addition of the Project. Aerial surveys that were conducted by Ministry of Natural Resources in WMUs 01D, 17, and 18A will be used to characterize moose populations at existing conditions and compare to during construction and operations. Aerial surveys could be conducted at least twice during construction and at a regular interval (such as every 3 years) during operations. The need for surveys further into operations will be determined through engagement with Ministry of Environment, Conservation and Parks;
- Developing community-based monitoring program in consultation and collaboration with Indigenous communities aimed to monitor Indigenous harvest

to identify potential changes to moose hunter harvest in response to increased human access during construction and operations. Monitoring Indigenous harvest through community-led programs will provide information on Indigenous hunter harvest demand and success, and moose population trends. Information on Indigenous harvest from these community-led programs could be used to inform non-Indigenous hunting quotas set by the Ministry of Natural Resources as a method of collaboratively managing moose populations in the moose Regional Study Area. Action levels or triggers for implementing adaptive management measures would be determined through collaboration with Indigenous communities and the Ministry of Natural Resources;

- A comprehensive Moose Access and Monitoring Plan will be developed in collaboration with Indigenous communities to identify high-risk moose collision zones to inform adaptive management (in other words, the implementation of signage and reduced speed limits) and for long-term monitoring of moose-vehicle collisions. The plan would be developed to protect the safety of people and moose. High-risk moose collision zones would be identified through community-based observations, collision reporting by Ontario Ministry of Transportation, and results from long-term monitoring of moose occurrence described above (in other words, Global Positioning System collars, remote cameras and aerial surveys);
- Designing a long-term sensory disturbance monitoring program, in consultation and collaboration with Indigenous communities, aimed to detect changes in ungulate behaviour in response to noise during construction and operations. This program could fill knowledge gaps and act as a research component of the Preliminary Biodiversity Offset Plan (**Appendix AB**); and
- Monitoring will follow standardized / established methods. A monitoring schedule, description of performance indicators that will be used to evaluate the effectiveness of mitigation measures, and adaptative measures to be implemented if necessary to address issues or problems identified during construction monitoring will be detailed prior to construction. The details of the ungulate monitoring programs will be described in the Environmental Protection Plan.

14.2.2.5 Physiography, Terrain and Soils

During detail design, a Project-specific Soil Management Plan will be developed, which could include the following:

- Slope stability monitoring during land clearing, site preparation, and construction of facilities, especially road components adjacent to rivers, creeks, and streams;

- Monitoring for admixing of soil, compaction, and erosion during clearing, contouring, and excavation activities;
- Monitoring of transportation of soil and stockpiling activities for signs of erosion;
- Monitoring of erosion and sedimentation control measures to avoid and minimize sediment mobilization from disturbed areas to drainages, wetlands, or watercourses;
- Monitoring of soil stockpiles and the Construction Disturbance Area for invasive species such as weeds. If invasive species are identified within the Construction Disturbance Area, a response plan will be prepared;
- Monitoring and managing reclamation concerns pertaining to soil erosion, revegetation, and slope stability; and
- Monitoring of aggregate rehabilitation to fully assess the effectiveness of rehabilitation and detect any unintended effects.

14.2.3 People

14.2.3.1 Aboriginal and / or Treaty Rights and Interests

The following Aboriginal and / or Treaty Rights and Interests-specific mitigation measures are proposed and must be confirmed with all relevant parties, including Marten Falls First Nation and the province:

- Collaboration with local existing environmental advisory committees to support the development and implementation of all environmental monitoring programs. The objective is to include Indigenous interests and perspectives, particularly concerning resources utilized for rights-based purposes. In the absence of an existing advisory committee with an aligned mandate to Marten Falls First Nation, a Terms of Reference between relevant agencies and Indigenous community will be established.
- Involve Indigenous community members in fieldwork and data collection. This participatory approach helps to weave Indigenous Knowledge, experience, values, and perspectives into the monitoring process.
- Develop a system to incorporate seasonal observations from Indigenous hunters, trappers, and land users who have firsthand experience with caribou movements to complement scientific data and provide real-time information.

14.2.3.2 Acoustic and Vibration Environment

A noise monitoring program is not recommended for the Project. Vibration monitoring is expected to be required for both temporary quarries and general construction blasting activities to align with Ministry of the Environment, Conservation and Parks / Ministry of Natural Resources requirements and general industry practices, respectively. Monitoring requirements will be considered and assessed once detailed information regarding the blast designs are available. Based on typical blasts, monitoring would be recommended for construction blasting within 250 metres and quarry blasts within 500 metres of receptors verified to be vibration sensitive.

14.2.3.3 Cultural Heritage

Construction monitoring for this discipline will be further determined based on the results of the Cultural Heritage Evaluation Reports described in **Section 14.1.3.3**.

14.2.3.4 Archaeology

Construction monitoring for this discipline will be further determined based on the results of the Stage 2 Archaeological Assessment described in **Section 14.1.3.4**.

A Stage 3 site-specific archaeological assessment is recommended for the Caviar (EiIp-1) site. Avoidance and protection are the preferred options either through project redesign or excluding or incorporating the area of the archaeological site into the development plan. Given that the site is located on the periphery of one of the route options, avoidance and protection might be possible upon choosing the preferred route. The site could therefore be avoided and protected during construction and the integrity of the area could remain intact. Should an avoidance and protection strategy for the Caviar (EiIp-1) site be implemented during construction, it must include:

- Placement of a temporary barrier around the site, including a 20-metre protective buffer of land surrounding the site;
- Monitoring by a licensed consultant archaeologist for any construction activities that occur within 70 metres of the site;
- The issuance of “no-go” instructions within the 20-metre buffer to all onsite construction personnel or others involved in the construction process (for example, engineers and architects) (Government of Ontario, 2011, Section 4.1.1);

- Illustration of the location of the area to be avoided on contract drawings, including explicit instructions to avoid the area;
- The presence of a licensed archaeologist onsite to inspect fence installation, inspection of the site by a licensed archaeologist after the completion of all soil-disturbing activities, and reporting of the effectiveness of the avoidance and protection strategy to the Ministry of Citizenship and Multiculturalism; and
- Should future repairs or improvements be required near the Caviar (EiIp-1) site or should changes to the current Project Study Area be required, archaeological monitoring by a licensed archaeologist will be required to confirm that the No-Go zone remains in place and that the archaeological site is protected from construction or soil disturbance activities.

14.2.3.5 Atmospheric and Greenhouse Gas

A construction monitoring program is recommended as a mechanism to help mitigate and / or identify potential conditions that may lead to air quality impacts from construction-related activities. A monitoring program, where feasible, may involve either or both air monitoring as well as construction activity monitoring. Construction activity may include verification that construction best management practices are being applied or identify where additional efforts / mitigation techniques may be necessary to help reduce air quality impacts. Construction monitoring may be beneficial in locations where sensitive receptors are in close proximity to the Construction Disturbance Area. Details specific to the scope of the monitoring program would need to be evaluated further following final detail design phases of the Project. Engagement with the Ministry of the Environment, Conservation and Parks to establish an appropriate monitoring program may be beneficial.

14.2.3.6 Community Well-Being

During construction, the following monitoring programs are proposed:

- Owner / operator to implement a monitoring program and perform safety checks at work camps and entry points (for example, airport) for alcohol and substances to prevent entry into the community;
- Owner / operator will develop a community-based reporting system that enables Indigenous community members and employees to anonymously report concerns, including those relating to violence, harassment, and crime, providing an option for anonymous reporting;

- Owner / operator to provide training and hand-off of all reporting mechanisms that are implemented by the owner / operator, so that the data remains in the hands of the community to support long-term response and prevention; and
- Owner / operator to develop an onsite safety and emergency preparedness program to include:
  - Implement onsite fire suppression systems, including sprinklers and fire extinguishers, to minimize reliance on local fire services;
  - Provide onsite medical care (paramedics, first aid stations, medics) to reduce pressure on local emergency response services;
  - Train and employ onsite security personnel to monitor safety compliance and enforce safety policies, reducing the strain on local police;
  - Work with the Ministry of Health and other appropriate government agencies to develop a coordinated emergency response plan with local responders for efficient handling of construction-related incidents requiring additional personnel; and
  - Establish emergency response plans, including clear communication protocols between the construction teams and local emergency responders.

Access to Clean Water - Water Quality:

- During construction, monitoring of surface water quantity and quality parameters (including but not limited to water taking and discharge rates, pH, total suspended solids, turbidity, temperature, dissolved oxygen, biochemical oxygen demand, and other contaminants of concerns as required). Monitoring of total suspended solids and / or turbidity instrumented measurements and / or visual observations), as well as visual inspections to confirm the presence or absence of oil or sheen.
- A construction groundwater monitoring program to continue the pre-construction monitoring through construction activities to identify and quantify any impacts to groundwater levels or quality resulting from construction activities. Groundwater quality should be sampled at the monitoring stations at least monthly for the same parameters as the pre-construction monitoring.

Traditional Foods Quality:

- During construction, a construction monitoring program is recommended as a mechanism to help mitigate and / or identify potential conditions that may lead to air quality impacts from construction-related activities. An air monitoring station

should be set up in Marten Falls throughout construction and into operations. Air monitoring in the community should have transparency in data to allow sensitive individuals to be aware of levels and remain inside during times of high particulate concentrations.

14.2.3.7 Land and Resource Use

The Contract Administrator should work with the Service Provider and Proponent to provide continuous consultation efforts to communicate with all land users to address potential safety concerns for access to the site during construction. Implement monitoring measures as outlined in the air quality, noise, visual, surface water, fish, wildlife, and ungulates technical reports to manage potential impacts related to remote outfitters.

14.2.3.8 Visual Environment

Construction-phase monitoring will confirm that construction activities and mitigation measures are implemented as designed, and to detect any exceedance of predicted contrast levels early enough for corrective action.

Key activities:

- Weekly field checks from photograph points and along staked limits during active clearing; compare to edge plans;
- Site layout review versus “staging outside view cones” plan, prior to set-up and after any relocation, and photograph captures;
- Daily visual plume logs during dry / windy conditions for visible dust beyond right-of-way or persistent foliage lightening in absolute no-go protected or priority view cones; surface reflectance spot checks (qualitative);
- Night audits at first night use per work front, then weekly if night works recur; lux spot checks at ground level (qualitative pass / fail); and photograph captures;
- As-built checks after bulk earthworks and post-armouring; photographs from water level;
- Annual checklist plus photographs (seeding, organics, decommissioning of temporary access) during construction and into the first year of operations;
- Monthly visual compliance memo during active works with a one-page dashboard (indicators, triggers hit, actions taken); and
- Construction notices coordinated with outfitters / park staff for peak activities at major crossings (to support trip planning and reduce exposure).

14.3 Operations Monitoring Program

Operations begins when construction on the roadway and associated facilities is considered complete, and the roadway and all facilities are open to the public. This may occur in phases depending on the sequencing of the construction activity. Maintenance generally refers to any regularly planned or emergency maintenance that may be required to keep the roadway up to the standards expected by the province or other regulatory bodies. Any permits for significant work during this period would be obtained through a separate Class Environmental Assessment or other process and are not considered here. More information on the details noted in the sections below can be found in the respective disciplines Technical Support Document in the appendices of the Environmental Assessment / Impact Statement.

14.3.1 Water

14.3.1.1 Surface Water

During operations, the following monitoring programs will be required:

- Monitoring / inspections of all new permanent water crossing structures (culverts and bridges) and roadside drainage features for physical function and condition in accordance with the Ministry of Transportation inspection guide and manual (Ministry of Transportation, 2008; 2022b); and
- Monitoring of water quality, sediment quality, and streamflow conditions at waterbodies that include greater sensitivity or implication to change from the standpoint of fish habitat, Species at Risk, channel stability, drainage pattern, or other environmental considerations. The specific monitoring locations will be determined during the permitting and design stages of the Project; however, it is expected that waterbodies of varying size (small, medium, large) would be captured, recognizing that this would allow the performance / effectiveness of mitigation and enhancement measures to be evaluated at a range of scales.

14.3.1.2 Fish and Fish Habitat

During operations the following monitoring programs will be required:

- Culverts and bridges will be regularly inspected and maintained to prevent blockages from forming and causing ponding or backwater effects. Where culverts and bridges are installed at fish-bearing waterbodies, Fisheries and Oceans Canada’s Codes of Practice will be followed for debris removal activities

(such as, gradual removal such that flooding downstream, extreme flows downstream, release of suspended sediment, and fish stranding can be avoided) (Fisheries and Oceans Canada, 2025). Inspection frequency will be adjusted where appropriate to take into account changing climate conditions over time; and

- A program will be conducted to verify that erosion and sediment control measures have been successful (such as bank restoration and revegetation), and that the stability of each waterbody crossing is maintained (in other words, the channel has not washed out). The post-construction monitoring will occur within one full growing season after the completion of construction, but timing may be extended if needed. The integrity of the permanent crossing structures will be inspected regularly (annually in spring). Any changes to the morphology of the waterbody channel affecting fish habitat quality or quantity will be identified and addressed, as needed.

14.3.1.3 Groundwater and Geochemistry

During operations, the following monitoring programs are recommended:

- Where no impacts have been identified, the construction monitoring programs noted above can be ended at sites that have been fully decommissioned in accordance with the Project plans. Where impacts are expected to develop over longer time periods, such as settlement of roads built over peatlands, monitoring should continue long enough to confirm that conditions have stabilized. Any groundwater monitoring wells no longer used for monitoring should be decommissioned in accordance with Ontario Regulation 903 Wells;
- At sites where impacts on groundwater levels or quality have been identified, the groundwater monitoring programs should continue, as per the construction monitoring program, until a return to baseline equivalent conditions is observed or a site-specific remediation monitoring plan is implemented as determined by the qualified person retained for environmental monitoring of the Project; and
- For sites that will continue to be used during operations the groundwater monitoring programs detailed above should continue along with any activities that may affect groundwater. For example, if a pit or quarry site is used intermittently, each use of the pit or quarry should be considered like a construction phase and the monitoring guidelines followed as above.

14.3.1.4 Peatlands

During operations, the following monitoring programs will be required. These programs will be further detailed during subsequent Project phases, in consultation with Indigenous communities:

- A program designed to monitor and manage any rehabilitated and restored peatland communities as well as any wetland offset areas. Details regarding the number of monitoring locations, level of effort and length of the monitoring period will be determined during detail design, if any peatland communities are restored or created;
- A program designed to monitor installed groundwater wells to confirm water flow beneath the road is being maintained. Monitoring will occur at the same locations established during pre-construction and will occur three times annually (spring, summer, fall) for a length of time to be determined during detail design;
- A program designed to monitor peatland community responses to any potential changes in hydrogeology. Details regarding the number of monitoring locations and the length of the monitoring period will be determined in subsequent Project phases;
- A program to monitor for peatland condition in the vicinity of Project activities. The program will include science-based thresholds or indicators of peatland condition based on research and established standards, as well as mitigation and adaptive response plan to prevent long-term damage or carbon release. Details regarding the number of monitoring locations and the length of the monitoring period will be determined in subsequent Project phases; and
- In addition to the operations surface water monitoring programs specified in the Surface Water Technical Support Document (**Appendix F**), monitoring of peatland hydrology will also be conducted. The requirements of this monitoring program will be determined at detail design.

14.3.2 Land

14.3.2.1 Vegetation

During operations, the following monitoring programs will be required. These programs will be further detailed during subsequent Project phases, in consultation with Indigenous communities:

- A program designed to monitor and manage rehabilitated and restored vegetation communities as well as any wetland offset areas. Details regarding

the number of monitoring locations, level of effort and length of the monitoring period will be determined in subsequent Project phases;

- A program designed to monitor installed groundwater wells to confirm water flow beneath the road is being maintained. The number of monitoring locations, their placement and the length of the monitoring period will be determined in subsequent Project phases; and
- A program designed to monitor vegetation community responses to any potential changes in hydrology or hydrogeology. Details regarding the number of monitoring locations and the length of the monitoring period will be determined in subsequent Project phases.

14.3.2.2 Wildlife

Engagement and consultation with Indigenous communities and federal and provincial regulators, as well as requirements outlined in federal and provincial permits, will determine the monitoring programs during operations. As required by the Tailored Impact Statement Guidelines (Impact Assessment Agency of Canada, 2020a), opportunities to participate in the development and implementation of the operations monitoring program will be provided for representatives from Indigenous Groups.

During operations, the following monitoring programs may be required:

- A public reporting system to track report incidental wildlife observations and wildlife-vehicle collisions during and operations, will be developed;
- Effectiveness of reclamation efforts will be monitored and managed post-construction, including confirmation that vegetation communities that naturally regenerate (or were planted) are similar to adjacent vegetation communities; and
- Monitoring for effectiveness of mitigation measures is a requirement of the Tailored Impact Statement Guidelines (Impact Assessment Agency of Canada, 2020a) and may include monitoring of eco-passages for wildlife. As details of their implementation are developed in future design stages, monitoring details will be added to the post-construction monitoring program.

Given the duration and intensity of the construction phase, a Before-After Control-Impact Study will be conducted as discussed in **Section 14.3.2.2**. It will begin prior to construction and continue during operations to allow for a quantitative assessment of potential effects of the Project. Due to the extended length of construction (3 to 10 years) and the segmented approach to construction, it is recommended that the study be initiated during construction for segments built early in the development of the Project so

as not to miss the initial years of post-construction (in other words, prior to the completion of the road). Monitoring during operations (in other words, following completion of the Project) would be a continuation of the Before-After Control-Impact Study.

The purpose of the Before-After Control-Impact Study monitoring program will be to determine the efficacy of mitigation measures, verify the predictions in the assessment**,** to guide any future measures that could be implemented during operations, and to fulfill Species at Risk permitting requirements. The Before-After Control-Impact Study will be based on the methods implemented for the existing conditions study.

For species designated as Threatened or Endangered under Ontario's *Endangered Species Act* (Government of Ontario, 2007), it is anticipated that post-construction monitoring will be a requirement of permitting under the Act.

The following monitoring is anticipated to be required as part of permitting:

- Wolverine hair snag / camera trap surveys: monitoring of wolverine population that interacts with the Project Local Study Area to allow for modelling of the wolverine population density during operations; and
- Bat maternity season acoustics: monitoring to confirm continued presence of Species at Risk bats at stations within the Project Local Study Area as well as relative bat activity levels during operations.

In addition to the monitoring requirements for valued components subject to *Endangered Species Act* permitting, the Tailored Impact Statement Guidelines (Impact Assessment Agency of Canada, 2020a) requires post-construction monitoring surveys be undertaken to evaluate whether there are changes in the valued component communities following construction and evaluate the effectiveness of applied mitigation.

The following monitoring is recommended to satisfy the requirements of the Tailored Impact Statement Guidelines:

- Winter snow tracking: to monitor the abundance and distribution of furbearers during construction and operations;
- Beaver lodge survey: to monitor the abundance and distribution of beavers during construction and operations;
- Remote camera program: to monitor the occurrence and distribution of wildlife during construction and operations. Additional details on the recommended remote camera program are provided in the Ungulates Technical Support Document (**Appendix M**); and

- Autonomous recording unit surveys for anurans: to monitor species presence and distribution during construction and operations.

The final monitoring program will be determined in consultation with Indigenous communities and federal and provincial regulators.

14.3.2.3 Birds

A Before-After Control-Impact Study is proposed for operations monitoring. Data from operations monitoring will be compared to data from reference sites (in other words, sites not affected by disturbance) and data collected prior to construction [in other words, baseline survey (2018 to 2022) point count and autonomous recording unit data] to determine population trends and determine if predictions made in the Environmental Assessment are valid. Field work will be completed and led by avian biologists, with support from Indigenous Environmental Monitors, where possible.

During operations, the following monitoring programs will be required:

- Autonomous recording unit and point count surveys at selected reference sites (in other words, locations surveyed in the alternative Project route Local Study Area during breeding bird, nightjar, and marsh bird baseline surveys from 2018 to 2022). Autonomous recording unit and point count surveys will be completed every 2 years for a period of 6 years; the need for surveys beyond 6 years will be determined in consultation with Environment and Climate Change Canada;
- Two roadside North American Breeding Bird Survey routes (each 40 kilometres long and containing 50 survey locations) will be initiated along the Project (in other words, one transect along the southern portion of the Project and one transect along the northern portion of the Project). The placement of each route will be negotiated with Environment and Climate Change Canada. Each route will be surveyed annually with the goal for the routes to be completed by the same observer for a period of 5 years; the need for surveys beyond 5 years will be determined in consultation with Environment and Climate Change Canada. Surveys will be completed in accordance with Environment and Climate Change Canada and United States Geological Survey standards. Refer to the Preliminary Biodiversity Offset Plan (**Appendix AB**) for more information;
- Three roadside Canadian Nightjar Survey routes (each 20 kilometres long and containing 12 survey locations) will be initiated along the Project (in other words, one transect along the southern portion of the Project, one transect along the middle portion of the Project, and one transect along the northern portion of the Project). Nightjar surveys will be focussed on the detection of Common

Nighthawk and Eastern Whip-poor-will. The placement of each route will be negotiated with Birds Canada and / or Environment and Climate Change Canada. Each route will be surveyed annually with the goal for the routes to be completed by the same observer for a period of 5 years; the need for surveys beyond 5 years will be determined in consultation with Environment and Climate Change Canada. Surveys will be completed in accordance with Birds Canada survey standards. Refer to the Preliminary Biodiversity Offset Plan (**Appendix AB**) for more information;

- A minimum of 10 Marsh Monitoring Program survey stations will be initiated along the Project (in other words, spaced evenly along the Project, where suitable habitat is present). The placement of each station will be negotiated with Birds Canada and / or Environment and Climate Change Canada. Each survey station will be surveyed annually with the goal for the routes to be completed by the same observer for a period of 5 years; the need for surveys beyond 5 years will be determined in consultation with Environment and Climate Change Canada. Surveys will be completed in accordance with Birds Canada survey standards. Refer to the Preliminary Biodiversity Offset Plan (**Appendix AB**) for more information; and
- A minimum of 20 targeted survey stations for Short-eared Owl will be surveyed each year, over a period of 3 years along the Project (in other words, spaced evenly along the Project, where suitable habitat is present; total of 60 surveys). Each survey station will be surveyed a minimum of once over the 3-year period of monitoring and the total monitoring effort will equal or be greater than 60 survey stations completed. Survey stations are not anticipated to be repeated to align with greater spatial coverage throughout the Project. The placement of each station will be chosen to align with the species breeding habitat requirements.

14.3.2.4 Ungulates

Engagement and consultation with Indigenous communities and federal and provincial regulators during the permitting phase, as well as requirements outlined in federal and provincial permits, will determine the monitoring programs during operations.

An Ungulates Management and Monitoring Plan will be developed as part of the Environmental Protection Plan. Recommendations for mitigations and monitoring approaches provided by First Nations during the comment period of the Draft Environmental Assessment / Impact Statement will be considered for inclusion in the Ungulates Management and Monitoring Plan.

A sensitive data license agreement will be established with the Ministry of the Environment, Conservation and Parks' Species at Risk Branch for the Project (such as the owner / operator) to acquire boreal caribou protected habitat information, which will support other proposed mitigation commitments during operations.

A Before-After Control-Impact Study is proposed for operations monitoring to allow for quantitative assessment of potential effects of the Project. If a Before-After Control-Impact Study was initiated in construction (**Section 14.2.2.4**), this would be a continuation. Data from operations monitoring will be compared to data collected prior to construction and data collected during construction to determine if predictions made in the Environmental Assessment are valid and to monitor changes in population trends and habitat use through time. Potential approaches to Before-After Control-Impact monitoring are described in **Section 14.2.2.4**.

Monitoring during operations will follow standardized / established methods. A monitoring schedule, description of performance indicators that will be used to evaluate the effectiveness of mitigation measures, and adaptative measures to be implemented if necessary to address issues or problems identified during operations monitoring will be determined through engagement with regulators. An Indigenous Environmental Monitor would be included in monitoring programs during operations.

14.3.2.5 Physiography, Terrain, and Soils

Inspections and maintenance of roadside ditches and culverts will be conducted as appropriate to limit the risk of road washout or sediment release to the environment. The frequency of these inspections will likely vary depending on weather events, amount of traffic, and season.

A program will be conducted to verify that erosion and sediment control measures have been successful (for example, bank restoration and revegetation) and that the stability of each waterbody crossing is maintained (in other words, the channel has not washed out). The post-construction monitoring will occur within one full growing season after the completion of construction, but timing may be extended if needed.

14.3.3 People

14.3.3.1 Aboriginal and / or Treaty Rights and Interests

The following Aboriginal and / or Treaty Rights and Interests-specific mitigation measures are proposed and must be confirmed with all relevant parties, including Marten Falls and the province:

- Collaboration with local existing environmental advisory committees to support the development and implementation of all environmental monitoring programs. The objective is to include Indigenous interests and perspectives, particularly concerning resources utilized for rights-based purposes. In the absence of an existing advisory committee with an aligned mandate to Marten Falls First Nation, a Terms of Reference between relevant agencies and Indigenous communities will be established;
- Involve Indigenous community members in fieldwork and data collection. This participatory approach helps to weave Indigenous Knowledge, experience, values, and perspectives into the monitoring process; and
- Develop a system to incorporate seasonal observations from Indigenous hunters, trappers, and land users who have firsthand experience with caribou movements to complement scientific data and provide real-time information.

14.3.3.2 Acoustic and Vibration Environment

No operational monitoring for acoustic is recommended for the Project.

Vibration monitoring is expected to be required for permanent quarries to align with Ministry of the Environment, Conservation and Parks / Ministry of Natural Resources requirements. Monitoring requirements will be considered and assessed once detailed information regarding the blast designs are available. Based on typical blasts, monitoring would be recommended for quarry blasts within 500 metres of receptors verified to be vibration sensitive.

14.3.3.3 Cultural Heritage

Operational monitoring for this discipline will be further determined based on the results of the Cultural Heritage Evaluation Reports described in **Section 14.1.3.3**.

14.3.3.4 Archaeology

Operational monitoring for this discipline will be further determined based on the results of the Stage 2 and Stage 3 Archaeological Assessment described in **Section 14.1.3.4**.

14.3.3.5 Atmospheric and Greenhouse Gas

The development of best management plans to mitigate fugitive dust generating potential during operations is recommended.

Due to the size of the road network, as well as its geographic location, feasibility / limitations will be present for long-term operations monitoring. It is recommended that consideration of input gathered through other technical monitoring programs specific to potential air quality concerns (in other words, potential dust deposition on vegetation) is completed and evaluated for consideration of future mitigation or monitoring options.

14.3.3.6 Community Well-Being

During operations, the following monitoring programs are proposed:

- The road owner will need to engage with law enforcement to implement increased monitoring of traffic and reckless driving to reduce road safety incidents.
- To address potential effects anticipated during operations, the owner / operator will establish several different working groups with Marten Falls First Nation and Aroland First Nation to meet regularly to discuss community-proposed topics in relation to the Community Access Road. In many cases, these working groups should be established in detail design and then carry through construction and, potentially, into operations.

Access to Clean Water – Water Quality

- During operations, monitoring of water quality, sediment quality, and streamflow conditions at waterbodies that include greater sensitivity or implication to change from the standpoint of fish habitat, Species at Risk, channel stability, drainage pattern, or other environmental considerations. The specific monitoring locations will be determined during the permitting and design stages of the Project; however, it is expected that waterbodies of varying size (small, medium, large) would be captured, recognizing that this would allow the performance / effectiveness of mitigation and enhancement measures to be evaluated Monitoring of surface water quantity and quality parameters will include but not

limited to water taking and discharge rates, pH, total suspended solids, turbidity, temperature, dissolved oxygen, biochemical oxygen demand, and other contaminants of concerns as required). Monitoring of total suspended solids and / or turbidity instrumented measurements and / or visual observations, as well as visual inspections to confirm the presence or absence of oil or sheen;

- An operations groundwater monitoring program to continue the construction monitoring until sites without impacts are decommissioned. Site where impacts to groundwater were observed should continue monitoring until a return to existing equivalent conditions is observed or a site-specific remediation monitoring plan is implemented. Groundwater monitoring should continue at applicable sites used continuously or intermittently during operations, with monitoring starting and ending according to the established construction monitoring programs for the intermittently active sites; and
- During operation, it is recommended that consideration of input gathered through other technical monitoring programs specific to potential air quality concerns (in other words, potential dust deposition on vegetation) is completed and evaluated for consideration of future mitigation or monitoring options. An air monitoring station should be set up in Marten Falls throughout construction and into operations. Air monitoring in the community should have transparency in data to allow sensitive individuals to be aware of levels and remain inside during times of high particulate concentrations.

14.3.3.7 Land and Resource Use

Conduct monitoring measures as outlined in the air quality, noise, visual, surface water, fish, wildlife, and ungulates technical reports to manage impacts related to remote outfitters and recreation (fish and game harvesting) activities.

Monitoring programs should be established to monitor use of the land once the road is operational with respect to collisions and recreation activities (such as, boating, fishing and hunting) so that wildlife and fish populations impacts are monitored and noted during maintenance and rehabilitation. A public reporting systems should be developed to report vehicle-wildlife collisions.

Monitoring and surveying of harvested species should also continue as part of long-term monitoring as increased public access may introduce more hunting and fishing pressures from non-Indigenous hunters and anglers.

For future land development activities that might be facilitated by the Community Access Road, confirm both Marten Falls First Nation and Aroland First Nation are involved in the monitoring process.

14.3.3.8 Visual Environment

Operations monitoring focuses on verification and adaptive management, confirming that long-term visual conditions align with predicted residual effects.

Key Activities:

- Repeat daytime and night photograph sets from photograph point stations during:
  - Commissioning (as-built);
  - End of the first full growing season; and
  - Year 3 of operations;
- Annual (summer) night audits during moonless, clear conditions plus after any fixture changes to verify:
  - Absence of non-task lighting; and
  - No visible skyglow at crossings;
- Observational checks of headlight spill at identified lines of sight (with resident consent), conducted at commissioning and as requested if concerns arise; and
- Preparation of operations visual monitoring reports at the end of Year 1 and Year 3.

If year 3 monitoring confirms that visual contrast and visibility have stabilized within predicted ranges, monitoring may transition to issue-driven monitoring only.

14.4 Future Commitments

Future commitments build upon the information presented in **Sections 14.1** to **14.3** and note where additional work may be required to enhance the monitoring and other commitments described. These commitments included water, land and people but also include commitments made elsewhere within this Environmental Assessment / Impact Statement. These represent items that must be done throughout various stages of the Project. Where it is not described when something will occur, it is expected that it will be an item planned in pre-construction. This plan may include timing that defers the commitment to a later phase.

14.4.1 Water

14.4.1.1 Surface Water

There are no future commitments for surface water.

14.4.1.2 Fish and Fish Habitat

There are no future commitments for fish and fish habitat.

14.4.1.3 Groundwater and Geochemistry

There are no future commitments for groundwater and geochemistry.

14.4.1.4 Peatlands

The effectiveness of mitigation measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management.

A Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed and will be implemented for the Project to provide a net positive increase in wetland habitat (**Appendix AB**). The specific approach will be determined through consultation with Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, but will generally follow a hierarchy of restoration, reclamation and offset alternatives (such as financial compensation directed towards wetland research or inventory work to fill existing information gaps). The Preliminary Biodiversity Offset Plan will focus on activities within the same ecoregions as the Project (in other words, Ecoregions 2W and 2E), to the extent feasible, followed by opportunities available in adjacent ecoregions (such as Ecoregions 1E, 3W, and 3E) or other ecoregions where wetland ecosystems are rare (such as Ecoregion 6E or 7E) and offset activities may provide a larger overall benefit.

14.4.2 Land

14.4.2.1 Vegetation

The effectiveness of mitigation measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management.

A Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed and will be implemented for the Project to provide a net positive increase in wetland habitat. The specific approach will be determined through consultation with Environment and Climate Change Canada, Ontario Ministry of the Environment, Conservation and Parks and Ontario Ministry of Natural Resources, but will generally follow a hierarchy of restoration, reclamation and offset alternatives (such as financial compensation directed towards wetland research or inventory work to fill existing information gaps). The Preliminary Biodiversity Offset Plan will focus activities within the same ecoregions as the Project (in other words, Ecoregions 2W and 2E), to the extent feasible, followed by opportunities available in adjacent ecoregions (such as Ecoregions 1E, 3W, and 3E) or other ecoregions where wetland ecosystems are rare (such as Ecoregions 6Eor 7E) and offset activities may provide a larger overall benefit.

14.4.2.2 Wildlife

- The effectiveness of mitigation measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management. A Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed and will be included in the final report submission. Offsetting measures will be implemented for the Project to provide a net positive outcome for little brown myotis, northern myotis, wolverine, and wetland habitat that provides amphibian breeding habitat. The Offset Plan will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and Ontario Ministry of the Environment Conservation and Parks; and
- A proactive outreach and education program aimed at increasing awareness of the presence of wolverine within the area, the potential effects of incidental trapping on wolverine populations, and effective mitigation measures that reduce the likelihood of incidental wolverine trapping as outlined in Best Management Practices to Avoid Wolverine (Ontario Fur Managers Federation, 2018) will be developed and implemented.

14.4.2.3 Birds

The effectiveness of mitigation measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management.

A Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed and will be implemented for the Project to provide a net positive increase in migratory bird habitat. As part of the Preliminary Biodiversity Offset Plan, primary themes to provide a net

positive for migratory birds include designing surveys as part of the operation monitoring program to be in-line with existing citizen science programs and undertaking land acquisition, including outside of the primary study area that benefits over-wintering migratory birds found in the Project Study Area. Additional survey requirements for bird Species at Risk will be determined through correspondence and potential permitting with Environment and Climate Change Canada and Ontario Ministry of the Environment, Conservation, and Parks.

14.4.2.4 Ungulates

The effectiveness of mitigation measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management.

- A Preliminary Biodiversity Offset Plan (**Appendix AB**) has been developed and implemented for the Project to provide a net positive increase in caribou functional habitat. The Offset Plan will be developed following engagement and consultation with Indigenous communities, Environment and Climate Change Canada, and Ontario Ministry of Environment Conservation and Parks.

14.4.2.5 Physiography, Terrain, and Soils

The effectiveness of mitigation measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management.

14.4.3 People

14.4.3.1 Aboriginal and / or Treaty Rights and Interests

The effectiveness of mitigation and enhancement measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management.

14.4.3.2 Acoustic and Vibration Environment

The effectiveness of mitigation and enhancement measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management.

14.4.3.3 Cultural Heritage

Future Commitments for this discipline will be further determined based on the results of the Cultural Heritage Evaluation Reports described in **Section 14.1.3.3**.

14.4.3.4 Archaeology

Future commitments for this discipline will be further determined based on the results of the Stage 2 and Stage 3 Archaeological Assessment described in **Section 14.1.3.4**.

14.4.3.5 Atmospheric and Greenhouse Gas

There are no future commitments for atmospheric and greenhouse gas.

14.4.3.6 Community Well-Being

The effectiveness of mitigation measures will be evaluated during construction and operations and will be modified or enhanced as necessary through adaptive management.

14.4.3.7 Land and Resource Use

As a component of all phases of the Project, it is recommended that where possible Marten Falls First Nation and Aroland First Nation are included in the monitoring of other future land development activities that might be facilitated by the road.

14.4.3.8 Visual Environment

Future commitments confirm that visual environment mitigation and monitoring remain actionable and auditable through design, construction, and early operations.

14.5 Future Permits and Approvals

A comprehensive list of future permits and approvals is provided in Appendix AA. A brief summary is included below:

- *Endangered Species Act* permitting consultation with Ministry of the Environment, Conservation and Parks will be required for the following species: Bats (little brown myotis and northern myotis), and wolverine;
- The aggregate pits and quarries that are proposed through the Community Access Road will be subject to permitting requirements outlined within the

Ontario *Aggregate Resources Act* and its regulations. For a permit to be issued, additional studies, mitigation plans, consultation and monitoring commitments may be required. In addition to permitting requirements under the Ontario *Aggregate Resources Act*, permitting and approvals under other pieces of legislation may also be required for pit and quarry development, including:

- Ontario *Planning Act*;
- *Ontario Water Resources Act*;
- *Environmental Protection Act*;
- *Endangered Species Act*; and
- *Species at Risk Act*.

15. Summary and Recommendations

15.1 The Community Access Road

The Community Access Road will consist of the road itself, associated access roads, rest areas / pull outs, bridges, culverts, pits, and quarries:

- Approximately 184 kilometres of all-season gravel road of which 8 kilometres will be within Marten Falls;
- Bridge and / or culvert installations for river and stream crossings;
- Right-of-way, approximately 100 metres wide, cleared to a width of 60 metres;
- Two-lane roadway, approximately 12 to 13 metres wide;
- Posted speed limit of 80 kilometres per hour;
- Culverts to maintain water flow connectivity and balance water levels;
- Pits and quarry sites;
- Temporary access roads and construction of temporary crossings;
- Temporary work areas and camps, and
- Road maintenance facilities, rest stops, and pull-out areas.

The Final Environmental Assessment / Impact Assessment was completed on a preliminary design of the road, which means that the details on how the Community Access Road will be built are still conceptual and are presented only at a high level.

15.2 Existing Conditions and Effects Assessment

Environmental studies, both desktop and field, were completed by the technical disciplines to document and assess the existing conditions. A total of 18 technical disciplines are considered in the Final Environmental Assessment / Impact Statement. These were grouped into water, land and people. Each technical discipline used existing conditions information alongside the description of anticipated construction and operations activities. This was used to determine the potential interactions between the Community Access Road and the environment. After the potential interactions were determined, potential effects were identified, and strategies to avoid or mitigate the negative effects were examined. Mitigations are strategies to reduce the potential negative effects on the environment.

Through the proper use of mitigation measures (**Appendix AA**), the potential negative effects from the construction and long-term use of the Community Access Road are

expected to be effectively managed, minimized, or mitigated. The Community Access Road is also expected to realize positive benefits for the community of Marten Falls. From an environmental perspective, the Marten Falls First Nation supports the Community Access Road.

15.2.1 Water

Despite mitigation, significant residual effects are expected:

Peatlands: Residual changes to peatland ecosystems due to changes to groundwater that may alter drainage patterns, groundwater regimes, or groundwater quality. Direct habitat loss (less than 1 percent regionally) and potential changes to groundwater or drainage patterns. Effect severity is moderate due to vulnerability (ecosystem of conservation concern) and irreplaceability (common in this landscape, but limited ability to restore functional peatland ecosystems).

15.2.2 Land

Despite mitigation, significant residual effects are expected on terrestrial Key Biodiversity Components:

- **Boreal Caribou**: loss of Category 1 habitat, sensory disturbance, linear barrier effects, increased access-related mortality risk, and collision potential. Effect severity is high because of vulnerability (Threatened species) and irreplaceability.
- **Wolverine**: habitat removal, sensory disturbance, incidental take, increased access, and potential for vehicle collisions. Effect severity is high because of vulnerability (Threatened species) and irreplaceability.
- **Little Brown Myotis and Northern Myotis**: removal of roost habitat, sensory disturbance, minor collision risk. Effect severity is high because of vulnerability (Threatened species) and irreplaceability.
- **Migratory Birds (including Species at Risk)**: habitat loss, sensory disturbance, and increased edge habitat. Effect severity ranges from low (for non-SAR species), moderate for Special Concern species, and high for Threatened / Endangered species.
- **Raptor Species at Risk**: habitat loss and sensory disturbance. Effect severity is high for Short-eared Owl (Threatened species) and moderate for Bald Eagle (Special Concern species).

A precautionary ecological risk ranking approach identifies boreal caribou, wolverine, Species at Risk bats, and Threatened / Endangered migratory birds as high-priority components requiring offsetting. Peatlands, bald eagle, and special concern migratory birds are considered to have a moderate ecological risk ranking, and will benefit from offsetting approaches implemented for the high-priority Key Biodiversity Components.

15.2.2.1 Offsetting Approach

Offsets are applied as the final step in the mitigation hierarchy and must aim for no net loss, or preferably net positive impact, on biodiversity. Offset planning considers equivalency, additionality, timing, duration, location, and accountability, consistent with federal policy, provincial requirements, and international Business and Biodiversity Offsets Program principles.

15.2.3 People

The Community Access Road presents an opportunity for improved connectivity, economic growth, and long-term resilience for Marten Falls First Nation and surrounding communities. While the Project brings key benefits such as improved accessibility, lower costs for essential goods and services, and increased employment and business opportunities, it also introduces challenges that require careful management. By implementing proactive mitigation measures and ongoing monitoring, the Project aims to balance economic development with cultural preservation and environmental sustainability, allowing for future generations to benefit from a more connected community.

Aboriginal and Treaty Rights and Interests: The Project will enhance access and connectivity within the Local Study Area and to remote regions and expand access to sites and areas that support traditional land and resource use, including hunting, gathering, trapping, fishing, and areas for ceremonial and cultural practices. This improved connectivity to traditional harvest areas, ceremonial and teaching places reinforces cultural practices and intergenerational knowledge transfer while enhanced access to the land for traditional foods can bolster food security and sustain community food sharing.

Community Well-being: Key positive effects include improved accessibility to and from Marten Falls, leading to small increases in on-reserve population, positive effects on productivity and economic growth, and sustained tax revenues. During construction, employment opportunities may lead to an increase in the working-aged population, and potentially altering the gender balance within Marten Falls First Nation and Aroland First

Nation. Increased employment could encourage off-reserve members to return, leading to an increase in the on-reserve population in the communities. There will be increased employment and business opportunities for local and Indigenous workers and companies during construction, contributing to the creation of approximately 8,600 jobs in Ontario, increasing economic activity and providing high earnings for individuals. Construction will lead to increased tax revenues.

During operations, employment and business opportunities may also increase in the community, creating long-term economic growth. Year-round access will also reduce the cost of essential goods such as bottled water and building materials, making everyday necessities more affordable. Additionally, improved connectivity to the region and increased transportation options will create new opportunities for local businesses, employment, and community development, contributing to long-term resilience.

Land and Resource Use: The Project will enhance access to the remote lands and water resources, potentially resulting in increased recreation activity opportunities such as hunting and fishing. Populations of furbearers in the larger area are not predicted to be affected by the Project and improved access to the area may benefit trapping activities. Finally, the road corridor, once established, may facilitate future mining and energy development opportunities.

Despite mitigation, significant residual effects are expected on some key components:

Atmospheric Environment: The air quality assessment identified impacts from dust (particulate matter 2.5 micrometres, particulate matter 10 micrometres and total suspended particulate matter) to be significant. It should be noted that the air quality assessment considered no dust suppression mitigation measures, which is a very conservative approach. With this in mind, the Community Access Road has the potential to negatively affect air quality due to road dust emissions. However, applying mitigation methods can result in up to an 80% reduction of dust.

Community Well-being: The Project has the potential to negatively affect mental health and overall well-being through several interconnected pathways, including reduced connection to the land and changes in sense of place and identity associated with the presence of the road. Additional concerns include the possibility of increased substance use due to easier access to drugs and alcohol, as well as a reduction in the availability of traditional foods resulting from construction-related disturbances, overharvesting, and broader environmental pressures linked to the road. There is also a potential negative effect on the quality of traditional foods due to possible contamination.

15.3 Consultation

Marten Falls First Nation has been consulting and engaging on the Community Access Road with Indigenous communities, interested persons, and government agencies since 2019.

Relationship building has been at the core of consultation and engagement efforts. Over the years, progress has been made to establish lines of communication, increase active participation, and satisfy / resolve concerns and issues. Progress has also been made to host Council-to-Council meetings between Marten Falls First Nation and other Indigenous communities (for example, Eabametoong First Nation and Aroland First Nation) to discuss relationship protocols, approaches for meaningful consultation and engagement, and to provide updates related to the Community Access Road.

15.4 Recommendation

The Community Access Road will connect Marten Falls to Ontario's main highways, making travel safer and allow families to visit one another more easily. It will help lower the cost of food, fuel, and other supplies while improving community services such as health care, education, and wellness. The Community Access Road will also create new opportunities for the Community to grow and flourish.

As a multi-purpose road, it can also increase economic opportunities for Indigenous communities and others. The Community Access Road is anticipated to create jobs during construction and through operations. Additionally, it will provide Marten Falls First Nation members with access to employment opportunities, as they will be able to reliably commute to work year-round.

The Community Access Road will not solve all the Community's challenges, but it does represent a step in a positive direction. It opens the door to new opportunities to grow as a community and offers hope for a better future. As Chief Achneepineskum puts it, "It is not just a path to progress; it is a testament to our resilience, our vision for the future and our commitment to the well-being of our people." From a community point of view, Marten Falls First Nation supports the Community Access Road.

Environmental impacts from the Community Access Road to water, land, and people will be mitigated through monitoring programs and future commitments, as described in **Section 14**. Marten Falls First Nation recommends proceeding with the approval of the Community Access Road, considering its positive effects, monitoring programs, mitigation measures and future commitments.

Marten Falls First Nation looks forward to continuing the conversation on next steps throughout the Assessment Process.
